Results: We show that FXR activation inhibits the glucose-mediated induction of the LPK gene expression. Our hypothesis is that this inhibition could be due to an interference of FXR with ChREBP transcriptional activity. Our results show that the nuclear receptor FXR interacts physically with the transcription factor ChREBP but this interaction does not interfere with the nuclear translocation of ChREBP or its binding to the LPK promoter. Recent results suggest that the activation of FXR leads to a recruitment of Histone Deacetylases (HDAC) to the LPK promoter since a treatment with Trichostatin A blocks the FXR effect on the LPK gene expression.
Conclusion: These results demonstrate that FXR plays an important role in regulating the glucose-mediated induction of glycolysis and lipogenesis by interfering with ChREBP transcriptional activity.

Comparison of direct and indirect pathways of hepatic glycogen synthesis using the [1-13C]glucose and deuterated water methods in fed and healthy subjects
C. Barosa[1], A. Fagulha[2], L. Barros[2], M. Caldeira[3], M. Carvalheiro[2], J. Jones[1];
[1]Center for Neurosciences and Cell Biology, Coimbra, [2]Department of Endocrinology, University Hospital of Coimbra, [3]Department of Chemistry, University of Coimbra, Portugal.

Background and aims: Hepatic glycogen is synthesized by two distinct processes: the classical direct pathway from intact glucose units, and the indirect pathway involving 3-carbon intermediates. It is now well established that the direct pathway is the major route of hepatic glycogen synthesis in healthy subjects but its contribution is significantly reduced in both Type 1 and Type 2 diabetes. Direct and indirect pathway activities can be safely and noninvasively measured using stable isotope tracers to label the glycogen precursors and glucuronidation probes such as Paracetamol to sample the enrichment of UDP-glucose from these tracers. The analysis can be applied in a routine clinical setting and could potentially be a diagnostic tool for assessing hepatic glucose and glycogen metabolism. [1-13C]glucose is the most widely used tracer to quantify the contribution of the direct and the indirect pathways to the glycogen synthesis but it is relatively expensive. Moreover, both plasma and urine need to be collected and analyzed for 13C-enrichment analysis thus incurring a significant analytical burden. Deuterated water (2H2O) has advantages over [1-13C]glucose since it is less expensive and the analysis only requires a single urine sample. To date, the two tracers have not been verified against each other. Therefore, we administered both [1-13C] glucose and 2H2O to healthy subjects and compared the direct/indirect pathway contributions from both tracers for each subject.
Materials and methods: Six overnight-fasted healthy young subjects took a breakfast, were the CHO portion included 10 grams of [1-13C] glucose. A 2H2O load was ingested to attain body water 2H-enrichment of 0.3%. This enrichment was maintained throughout the study by providing drinking water enriched with 0.3% 2H2O. Paracetamol was taken for UDPG sampling as urinary Paracetamol glucuronide and a blood sample was also collected.

Paracetamol glucuronide and blood glucose were derivatized to MAG for 1H, 2H and 13C NMR analysis. Body water 2H-enrichment was also quantified by 2H NMR. Direct pathway from [1-13C] glucose ingestion was calculated by the analysis of excess 13C enrichment of C1 and C6 of MAG obtained from both glucuronide and plasma. Direct pathway from 2H2O was obtained from the 2H5/body water ratio.
Results: Direct pathway measured by 13C and 2H was 59% ± 7.34 and 61% ± 1.88 respectively while indirect pathway was 41% ± 7.34 and 39% ± 1.88. Data are presented as means ± standard errors.
Conclusion: In conclusion, direct and indirect pathway measured by 13C analysis after ingestion of [1-13C] glucose in the postprandial state, matches the data obtained by 2H NMR analysis of 2H enrichment from 2H2O under the same conditions.

New aspects of hepatic glucose phosphorylation by intracellular glucokinase localisation
M.T. Kaminski[1], S. Lenzen[1], S. Baltrusch[1,2];
[1]Institute of Clinical Biochemistry, Hannover Medical School, [2]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

Background and aims: Coupling of millimolar glucose concentrations to liver metabolism is mediated by the glucose phosphorylating enzyme glucokinase (GK) and vital to maintain glucose homeostasis. Only in liver a specific glucokinase regulatory protein (GRP) inhibits GK activity and mediates the GK nuclear import at low glucose. It is poorly understood so far whether GRP affects GK nuclear export at high glucose concentrations. Therefore one aim of this study was to elucidate the role of the GRP in GK nuclear export. Furthermore, a function of GK in the nucleus has not yet been ascertained. Recently we could establish a fluorescence resonance energy transfer (FRET) based glucose specific nanosensor (FLIPglu) to monitor intracellular glucose flux. Thus a second aim of this study was to characterize glucose uptake and metabolism in hepatocytes with respect to the cytoplasmic and nuclear compartments.
Materials and methods: Localization and translocation of GK and GRP were analyzed in primary rat hepatocytes in comparison to MIN6 beta cells by ECFP and EYFP fluorescent fusion proteins and through fluorescence distribution after photoconversion of a Dendra2 or PA-GFP fusion protein, respectively. Dynamic changes in the nuclear and cytoplasmic glucose concentration were determined in perifusion experiments in primary hepatocytes, COS cells and MIN6 cells expressing either the cytoplasmic FLIPglu or the nuclear FLIPglu-nuc.
Results: In hepatocytes a higher portion of the GRP has been identified in the nucleus compared to the cytoplasm. The nuclear/cytoplasmic ratio of the GRP was only marginally affected by glucose. In contrast the nuclear/cytoplasmic ratio of glucokinase was significantly higher at low as compared to high glucose. In MIN6 cells endogenously expressing GK but not GRP, comparable results were observed after overexpression of an EYFP-GRP protein. By selective photoconversion it was demonstrated that one fraction of the GRP protein pool in hepatocytes continuously shuttled between the nucleus and the cytoplasm, both at high and low glucose. While the cytoplasmic fraction of the GRP was completely mobile, in the nucleus an immobile fraction of the GRP was elucidated. Using compartment specific FLIPglu sensor expression it was shown that the cytoplasmic glucose uptake was accompanied by an only slightly time-delayed nuclear glucose uptake irrespective of the analyzed cell type. Interestingly, after removal of extracellular glucose the nuclear glucose concentration decreased twofold faster in hepatocytes compared to MIN6 cells and COS cells, which indicates that glucose phosphorylation takes place only in the nucleus of hepatocytes, where GK is present.
Conclusion: GK leaves the nucleus in a glucose dependent, but GRP independent manner. For the first time we have shown that after dissociation from the GRP, GK is active in the nucleus of hepatocytes. Our results open new therapeutic perspectives for the development of liver specific GK activating compounds interfering with the GK-GRP interactions.

PS 48 Clinical insulin resistance - effect of interventions

Insulin resistance alters post-prandial haemodynamic parameters: an impedance cardiography approach
S. Vigili de Kreutzenberg[1], F. Boscari[1], E. Rossi[1], G. Fadini[1], G. Ceolotto[1], S. Guerra[2], G. Sparacino[2], M. Bottero[3], A. Avogaro[1];
[1]Clinical and Experimental Medicine, Padova University, [2]Information Engineering, Padova University, [3]Cardiology Unit, SS Giovanni e Paolo Hospital, Venezia, Italy.

Background and aims: In postprandial state insulin regulates both metabolic and cardiovascular responses. In insulin resistance (IR) states, insulin action is impaired at both levels. However, the hemodynamic responses of postprandial phase in IR patients are poorly characterized. Impedance Cardiography (ICG), a relatively easy-to-use technique, allows a reliable beat-to-beat non invasive haemodynamic evaluation. We investigated cardiac/vascular hemodynamic response by ICG technique in fasting and postprandial state, in subjects with and without IR.
Materials and methods: In 66 volunteers (50 male, 16 female, age 48±8 years), without subclinical atherosclerosis, a mixed meal (10 kcal/kg; 55% carbohydrate, 15% proteins, 5% fats) was administered while basal and post-meal (180 min) continuous ICG monitoring was performed. Insulin sensitivity (Si) was determined by the minimal model analysis, and the following haemodynamic parameters were recorded: systolic and diastolic arterial blood pressure (BP), heart rate (HR), stroke volume (SV), cardiac index (CI), systemic vascular resistance index (SVRI), left cardiac work index (LCWI).
Results: According to the median value of Si (7.27×10^{-4}dl•kg^{-1}•min^{-1} per μU/ml) subjects were divided in insulin-resistant (IR; n 33) and insulin sensitive (IS; n 33). In fasting condition, IR showed higher values of systolic (p=0.003) and diastolic (p=0.002) BP and SVRI (p=0.011), compared to IS. In post-prandial state vasodilatation was comparable and synchronous (at 30 min) in IR versus IS (SVRI respectively -12.7±2.5% and -3.6±2.5%; p M-ANOVA 0.209), but the subsequent recovery (30-180min) was significantly impaired in IR (M-ANOVA 0.018). In post-prandial state haemodynamic parameters linked to cardiac function were not statistically different in IR vs IS.
Conclusion: IR subjects show a worse cardiovascular performance compared to IS in fasting condition. In post-prandial phase, IR associates with a shorter duration of vasodilatation in the absence of an altered cardiac performance. Hemodynamic alterations in both fasting and postprandial states are important features of insulin resistance.

631

Assessment of insulin signalling in isolated circulating leukocytes is feasible and parallels whole-body insulin resistance in prednisolone-treated healthy men
D.H. van Raalte[1], M.M.L. Linssen[2], E.B.M. Nascimento[2], M. Diamant[1], D.M. Ouwens[2,3];
[1]Department of Internal Medicine / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, [2]Department of Molecular Cell Biology, Leiden University Medical Centre, Netherlands, [3]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Centre, Duesseldorf, Germany.

Background and aims: Impaired insulin-stimulated glucose disposal in skeletal muscle is a hallmark of type 2 diabetes mellitus (T2DM). Thus, several defects in the insulin-signalling cascade in skeletal muscle were reported in subjects with impaired glucose metabolism or T2DM. Assessment of these defects in vivo requires laborious and invasive skeletal muscle biopsies. The aim of this study was to investigate whether it would be feasible to measure insulin signalling in more easily accessible circulating leukocytes. To this end, healthy men were treated with low- or high dose prednisolone in order to induce various levels of insulin resistance.
Materials and methods: Healthy men (n=21; mean±SE: age: 21±2; BMI: 22±2) underwent a hyperinsulinaemic-euglycaemic clamp at baseline and on day 14 of treatment with either prednisolone 30 mg daily (PRED30), prednisolone 7,5 mg daily (PRED7.5) or placebo (PLB). Blood samples were obtained at t=-5 min, t=5 min, t=10 min and t=20 min during insulin infusion (at 40 mU/m2•min) for isolation of peripheral leukocytes using an erythrocyte lysis buffer. The expression and phosphorylation (at Thr246) of

proline-rich Akt substrate of 40 kDa (PRAS40), a marker of the insulin-signalling cascade, was assessed by immunoblotting and densitometry analysis. Insulin sensitivity was quantified as the M-value, obtained during 90-120 min of insulin infusion.
Results: Both PRED7.5 and PRED30 vs. PLB decreased insulin sensitivity (mean difference -2.8±1.0 mg/kg•min, P = 0.03 and -4.5±0.9 mg/kg•min, P = 0.001 respectively). Insulin infusion increased phosphorylated PRAS40 (P-PRAS40)/total PRAS40 ratio at t=5 min, t=10 min and t =20 min as compared to t=-5 min by 35% (P < 0.05 for all). During treatment, P-PRAS40/total PRAS ratio was decreased in the PRED30 group (P = 0.05), but not in the PRED7.5 arm. The change in P-PRAS40/total PRAS40 ratio during treatment correlated with the change in M-value (R=0.447, P = 0.042).
Conclusion: Molecular aspects of insulin signalling and changes thereof can be measured in peripheral leukocytes and correlate with whole-body insulin sensitivity. Although the physiological role of these assessments in leukocytes requires further study, this method may provide an alternative, less-invasive tool to monitor changes in insulin signalling in health and disease.

632

Meal-related increases in microvascular vasomotion are impaired in obese individuals
A.J.H. Houben[1], A.M. Jonk[1], N.C. Schaper[1], P.W. de Leeuw[1], E.H. Serné[2], Y.M. Smulders[2], C.D.A. Stehouwer[1];
[1]Dept of Internal Medicine, Maastricht University Medical Centre, Maastricht, [2]Dept of Internal Medicine, VU Medical Center, Amsterdam, Netherlands.

Background and aims: Steady state hyperinsulinaemia during a hyperinsulinaemic euglycaemic clamp stimulates endothelium-dependent vasomotion as well as capillary recruitment, which contribute to increased glucose uptake; these phenomena have been shown to be blunted in obesity. If insulin's effects on microcirculatory function indeed play a physiological role in regulating insulin-mediated glucose uptake, such effects should be demonstrable not only during steady-state hyperinsulinaemia, but also after meal ingestion. The aim of the present study was to investigate the effects of an oral glucose load and a liquid mixed meal on cutaneous microvascular vasomotion in lean and obese subjects.
Materials and methods: A randomised, placebo-controlled trial was performed in 18 lean (BMI 22.5±1.7 kg/m^2) and 13 obese (BMI 34.0±3.5 kg/m^2) subjects, to examine the effects of a glucose drink (75 g glucose), a 495-kcal liquid mixed meal (60% carbohydrates, 25% proteins, 15% fat) or placebo (tap water) on microvascular function. Skin blood flow was measured by laser Doppler flowmetry (LDF). Vasomotion was examined by Fourier analysis of the LDF signal.
Results: Both the glucose drink and the liquid mixed meal, but not the water drink, induced hyperinsulinaemia. The levels of hyperinsulinaemia were higher in obese compared to healthy subjects (glucose drink: 98.1±82.5 vs. 39.2±17.0 mU/l, P<0.05; mixed meal: 99.8±78.9 vs. 52.7±20.5 mU/l P=0.07). Water intake did not alter the energy density of any of the five frequency components in either the lean and obese group. Intake of the glucose drink increased the endothelial component of vasomotion (P<0.05) in lean subjects. In lean subjects, intake of the mixed meal drink increased the energy density of all five frequency components (P<0.01, P<0.01, P<0.01, P<0.01, and P<0.05, respectively), and the total energy density of the entire spectrum (P<0.01). In obese individuals, neither the glucose nor the mixed meal drink had any effect on the energy density of the five frequency bands or the total energy density. The increase in the energy density of the endothelial, neurogenic, and respiratory frequency components and the total energy density in lean individuals in response to the mixed meal drink was significantly different from the response to the mixed meal drink in obese individuals (P<0.01, P<0.05, P<0.05, and P<0.01, respectively).
Conclusion: Our data demonstrate that ingestion of a meal increases microvascular vasomotion in lean individuals. In addition, we found that the increase in microvascular vasomotion with meal ingestion was impaired in obese individuals and that this lack of meal-induced stimulation of microvascular vasomotion paralleled blunted insulin-stimulated glucose disposal after meal feeding in these subjects. Thus, these data are consistent with a physiological role for insulin-stimulated microvascular vasomotion in insulin-mediated glucose uptake in the postprandial state.

Effects of starvation on insulin sensitivity and glucose metabolism in obese patients with type 1 diabetes mellitus
F. Musil, A. Smahelova, A. Ticha, R. Hyspler, J. Lesna, V. Blaha, L. Sobotka; Department of Metabolic Care and Gerontology, Charles University and University Hospital, Hradec Králové, Czech Republic.

Background and aims: At present time obesity is more frequently connected with type 1 diabetes mellitus (T1DM) in western population. The effect of reduced energy intake and several days of fasting is not fully known in this group of diabetic patients. The aim of our work was to study the influence of seven days of starvation on insulin sensitivity and glucose metabolism in obese patients with T1DM.
Materials and methods: We studied 14 obese patients with T1DM (42,6±9,4 years, BMI 32,4±2,1 kg m^{-2}) and 13 non-obese control patients with T1DM (36,9±13,9 years, BMI 22,6±2,1 kg m^{-2}). The insulin sensitivity and glucose oxidation were measured in obese T1DM patients before starvation, immediately after 7 days of starvation and 21 days thereafter. Control group was studied only after overnight starvation. Insulin sensitivity was measured using hyperinsulinemic euglycemic clamp (the 2-step hyperinsulinemic euglycemic clamp lasting 6 hours, period 1: 0 to 120 minutes 1 IU/kg/min of insulin and period 2: 120 to 360 minutes 10 mU/kg/min of insulin - Humulin R, Elly-Lilly, USA). Glucose oxidation and non-oxidative glucose disposal were measured before and during the clamp by indirect calorimetry - ventilated canopy system (VMAX, Sensormedics, Anaheim, USA). Evaluations of urinary urea nitrogen excretion was made to calculate protein oxidation. Mean±SD, T-test, ANOVA were used for statistical evaluation.
Results: All patients tolerated the period of starvation. Obese T1DM patients lost 6,1±1,1 kg. Glycaemia during starvation was maintained at 5 mmol/l by adjustment of basal insulin dose. Starvation reduced insulin-mediated glucose disposal in both phases of clamp (P<0,001). This was caused mainly by reduced glucose oxidation after starvation period (P<0,001). Non-oxidative glucose disposal was not changed.
Conclusion: One week of starvation transiently decreased insulin mediated glucose disposal in obese T1DM patients. This was namely caused by reduced glucose oxidation. To our best knowledge we are the first who described this effect.

Insulin infusion rate 10mU/kg/min,*P<0,001 obese during the time, #P<0,05 obese vs controls

Obese T1DM (n=14)	Before starvation	After starvation	21 days after starvation	Controls (n=13)
Glucose disposal (mg/min/kg)	9,69±1,48#	6,78±1,21*	9,31±1,16	12,02±2,16
Glucose oxidation (mg/min/kg)	2,81±0,52	0,88±0,98*	2,80±0,67	3,54±1,17
Non-oxidative glucose disposal (mg/min/kg)	6,88±1,44#	5,94±0,87	6,51±1,03	8,48±1,58

Adipocyte fatty acid binding protein in diabetes mellitus - effects of hyperinsulinaemia and acute angiotensin II type 1 receptor blockade
E. Švehlíková[1], M. Klementová[1], S. Kratochvílová[1], J. Kopecký Jr.[1], P. Wohl[1], L. Kazdová[1], P. Mlejnek[2], M. Pravenec[2], M. Hill[3], T. Pelikánová[1];
[1]Diabetes Center, Institute for Clinical and Experimental Medicine, [2]Institute of Physiology, Academy of Sciences of the Czech Republic, [3]Institute of Endocrinology, Prague, Czech Republic.

Background and aims: Beside of its regulatory role in lipid metabolism, adipocyte fatty acid binding protein (A-FABP) has been suggested to be involved in the development of insulin resistance. We investigated: a) plasma concentrations of A-FABP in parallel with its expressions in subcutaneous adipose tissue (SAT) and b) their response to acute hyperinsulinaemia and acute angiotensin II type 1 receptor blockade (ARB) in type 2 diabetes.
Materials and methods: 11 patients with type 2 diabetes (D) and 12 healthy age-matched control subjects (C) underwent: 1) hyperinsulinaemic-euglycaemic clamp (HEC); 2) HEC after acute ARB (losartan 200 mg) (AT-HEC) and 3) saline infusion (SAL) as a volume control examination. At 0 min and

240 min of the interventions blood sampling for assessment of plasma A-FABP and needle biopsies of abdominal SAT were performed. Adipose tissue samples were processed for real-time PCR method to quantify gene expressions of A-FABP, E-FABP (epidermal FABP, a minor FABP-isoform of adipose tissue) and PPAR-γ. For statistical analysis ANOVA with repeated measures was used (significances in Table: [a] Treatment effect p<0.05 - difference between interventions: HEC vs. AT-HEC vs. SAL; [b] Time effect p<0.05 - changes between time points: 0 min vs. 240 min).

Results: Plasma A-FABP was 1.6-fold higher in D relative to C (p<0.001). In D, a comparable decrease in plasma A-FABP was detected during both clamps, whereas no changes were observed during SAL. In C, time profiles of A-FABP differed between the clamps, showing an increase in basal concentrations in AT-HEC. A-FABP expression in SAT was 3.0-fold higher in D (p<0.001) without any dynamic changes during all interventions. Plasma A-FABP correlated positively with its expression (r=+0.59; p<0.001). Both A-FABP plasma concentrations and mRNA expressions were independently associated with BMI, waist circumference, glycaemia, insulinaemia and glucose disposal. E-FABP showed higher expressions in C (p<0.001). A-FABP/E-FABP mRNA ratio was 3.0-fold higher in D compared to C (p<0.001) without any changes within and between clamps. PPAR-γ expressions were lower in D compared to C (p<0.01), no dynamic changes were shown.

Conclusion: A-FABP plasma concentrations as well as expressions are increased in type 2 diabetes and they are closely associated with parameters of obesity, insulin resistance and hyperglycaemia. On the contrary, the expressions of E-FABP and PPAR-γ are decreased in diabetes. Hyperinsulinaemia differentially regulates A-FABP in D compared to C. In C but not in D, losartan stimulates basal A-FABP plasma concentrations without any effect on its expressions.

A-FABP plasma concentrations and expressions of selected genes in SAT. Data shown as mean (95% CI).

Fasting and postprandial hepatic glycogen content is not altered by systemic insulin delivery in type 1 diabetic patients after successful pancreas kidney transplantation

M. Stadler[1], C. Anderwald[2], D. Jankovic[2], M. Krssak[2], C. Göbl[2], Y. Winhofer[2], G. Pacini[3], M. Bischof[4], M. Haidinger[2], M. Saemann[2], F. Mühlbacher[5], A. Luger[2], R. Prager[1], M. Krebs[2];
[1]3rd Medical Department of Metabolic Diseases and Nephrology, Hietzing Hospital, Vienna, Austria, [2]Endocrinology and Metabolism, Medical University Vienna, Austria, [3]Metabolic Unit, ISIB-CNR, Padova, Italy, [4]Krankenhaus der Elisabethinen, Vienna, Austria, [5]Department of Surgery, Medical University Vienna, Austria.

Background and aims: Insulin replacement in Type 1 diabetes mellitus (T1DM) is usually performed via a systemic (subcutaneous) instead of the physiologic portal route. So far it is unclear whether this systemic route of insulin delivery might contribute to metabolic defects in these patients. Successful pancreas kidney transplantation (PKT) with systemic venous drainage is an ideal model of optimized systemic insulin therapy. Therefore, the aim of the present study was to investigate the effects of PKT on fasting and postprandial liver glycogen content.

Materials and methods: Using 13C-nuclear magnetic resonance spectroscopy (13C-NMR), liver glycogen concentrations were assessed in 9 T1DM patients after successful PKT (24±1kg/m², 47±3yrs, 3f/6m, fasting glucose 84±3mg/dl, HbA1c 5.1±0.2%) with systemic venous drainage and in 9 matching nondiabetic controls (CON) (24±1 kg/m², 47±3yrs, 3f/6m, 89±3 mg/dl, 5.4±0.1%) at fasting and after two standardized mixed meals.

Results: Liver glycogen concentrations at fasting (PKT:195±12, CON:209±10mM), after breakfast (PKT:216±12, CON:233±11mM) and after lunch (PKT:230±13 vs. CON:171±15mM), as well as the increment of liver glycogen content after the meals were comparable in PKT and CON. Mean and fasting concentrations of glucose, insulin, C-peptide and glucagon were similar in PKT vs. CON.

Conclusion: Despite systemic insulin secretion, T1DM after successful PKT exhibit unchanged fasting and postprandial liver glycogen stores in comparison with age-and BMI-matched non-diabetic controls. Thus, this study indicates that systemic insulin substitution does not cause alterations of hepatic glycogen storage.

The effect of liraglutide on metabolism in ApoE-/- mice with RNAi-mediated adiponectin gene inhibition

Z. Zhang[1], G. Yang[1], L. Li[2];
[1]Department of Endocrinology, the Second Affiliated Hospital, [2]Department of Clinical Biochemistry, Chongqing Medical University, Chongqing, China.

Background and aims: Liraglutide is an analogue of Glucagon-like peptide-1(GLP-1), researched and developed by Novonordisk. It can bind with the GLP-1 specific receptor, which belongs to the Islets of Langerhans β cells, promote the expression and biosynthesis of the pre-insulin gene, and facilitate the secretion of insulin in the genetic level. But its specific mechanism retains unknown. In our study, we have investigated the effects of Liraglutide on insulin sensitivity and glucose-lipid metabolism in $ApoE^{-/-}$ mice with RNAi-mediated adiponectin gene inhibition.
Materials and methods: High-fat diet fed male apoE-/- mice were randomly divided into adiponectin shRNA adenovirus injection group (ADI group, n=8), Liraglutide co-injection of adiponectin shRNA adenovirus group (HEA group, n=8) and adenovirus control group (GF group, n=6). The hyperinsulinemic-euglycemic clamp combined with 3-[3H] glucose was used as a tracer to assess the insulin sensitivity. Plasma FFA, insulin concentrations (PIns), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), TG and TC concentrations were measured.
Results: In the IVGTT, the group with 1mg· kg^{-1} Liraglutide, Bid, at time points of 5, 15, 30 min after glucose challenge, presented lower significantly than other groups in the blood glucose(P<0.01), with a significant increase in the plasma insulin at the points of 5 and 15 min(P<0.01). Fasting blood glucose (FBG), body weight, Free fatty acids (FFA),TC,TG,LDL-C,HDL-C and fasting plasma insulins (PIns) in $ApoE^{-/-}$ mice with Liraglutide and adiponectin shRNA adenovirus (HEA group) co-injection of were significantly lower than those with high-fat diet and adiponectin shRNA adenovirus injection (ADI group) (P<0.01). However, HDL-C showed a significant elevation, compared HEA with ADI group (P<0.05). During the steady-state of clamp, plasma insulin in ADI group was significantly higher than that in HEA group (P<0.01). Although FFA, TC and TG were suppressed in all groups, they were still higher in ADI group than those in HEA group(P<0.05). Glucose infusion rate(GIR) in HEA group were significantly higher than ADI group (P<0.01). In the end of clamp, glucose disappearance rate (GRd) was significantly lower, and HGP significantly higher in ADI group than HEA group (P<0.01).
Conclusion: Liraglutide administration can improve insulin resistance by increasing plasma adiponectin level in ApoE-/- mice with RNAi-mediated adiponectin gene inhibition.

Normalising effect of GLP-1 and Exendin-4 on the deleterious hepatic metabolism, of an obesity model

I. Gutiérrez-Rojas, P. Moreno, B. Nuche-Berenguer, I. Valverde, M.L. Villanueva-Peñacarrillo;
IIS-Fundación Jiménez Díaz, Madrid, Spain.

Background and aims: Obesity is often related with several metabolic alterations that can drive to insulin resistance and finally diabetes. GLP-1 and its structurally homologous peptide, exendin-4 (Ex-4), both have insulinotropic and antidiabetic actions and stimulatory effects on the glucose metabolism of extrapancreatics tissues such as liver and muscle. Here, we have studied the effect of GLP-1 and Ex-4 treatment, on Glut-2 expression and other parameters, in an obesity model (Ob) compared to normal (N).
Materials and methods: Ob model was obtained in adult Wistar rats by chronic feeding -5 weeks- with a "cafeteria diet", consisting in standard chow supplemented with cookies, liver paste, bacon, and whole-milk containing sucrose (333 g/l) and 10 g/l of a mineral and vitamin complex (65% energy derived from lipids). The N group was fed with standard chow and water *ad libitum* (8% calories from fat). Although weight was not different between N and Ob, the Ob model showed fasting plasma glucose, triglycerides (159±14 mg/dl, n=9) and cholesterol (94±4 mg/l, n=10) higher than N (overall mean: 145±7% Δ N-rats, p<0.001); no significant differences with N were detected in plasma insulin or GLP-1 -RIA-. Ob (n=5-10 rats/group) and N (4-10 rats/group) were treated (3 days), through an osmotic pump, with saline (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1nmol/kg/h). Blood samples were taken before and by the end of treatment for plasma measurements. In liver, we analyzed Glut-2 expression -protein, by Western blot, and mRNA, by RT-PCR- and also glycogen content -antrona method-.
Results: In Ob, liver Glut-2-mRNA was much lower than that in N animals (0.41±0.02 times N-control, n=10 rats, p<0.001), while Glut-2-protein was higher (123±10% N-control, n=14, p<0.05); GLP-1 treatment reduced the Glut-2-protein levels (64±4% Ob-control, n=7, p<0.001), without altering the mRNA value (0.96±0.04 times Ob-control, n=5); treatment with Ex-4 lowered the Glut-2-protein (60±4% Ob-control, n=7, p<0.001) to a value close to that in N (84±7% N-control), without modifying the mRNA expression (1.02±0.06 times Ob-control, n=5). The liver glycogen content in Ob rats (902±52 μg/mg protein, n=6), compared to than that in N animals (395±34 μg/mg protein, n=6), was much higher (228±13% N-control, n=6, p<0.001); treatment with GLP-1 reduced the liver glycogen content in Ob, to a value (396±15 μg/mg protein, n=5, p<0.001) undistinguible from that in N rats; Ex-4 also exerted a lowering effect on glycogen content in Ob rats (81±5% Δ Ob-control, n=5, p<0,02), to a level though (726±45 μg/mg protein, n=5, p<0.05) still higher (p<0.001) than that shown in the N group. Plasma glucose and insulin were not apparently different in any group or condition; yet, in the Ob group, GLP-1 lowered the higher than N triglycerides (-50±4% Δ Ob-basal, p<0.04, n=5 rats) to a value even lower than that in N (76±7% N-control, p<0.02), without modifying that of cholesterol; Ex-4 induced a reduction in both parameters, the magnitude of its effect on cholesterol being small but clear (-12±3% Δ Ob-basal, p<0.01, n=6), and that on triglycerides (-57±6% Δ Ob-basal, p<0.01, n=5) as that exerted by GLP-1.
Conclusion: Both, GLP-1 and Ex-4 have a normalizing effect on the high hepatic glycogen accumulation in this obesity model, perhaps through their lowering action upon the higher than normal liver Glut-2 expression, mainly at the translational process, and by reducing the also higher than normal circulating triglycerides levels.

Enhanced GIP and attenuated GLP-1 incretin effects during IVGTT in Wistar rats under DPP-4 inhibition

E.-J. Freyse, S. Berg, P. Heinke, K.-D. Kohnert, E. Salzsieder;
Institut für Diabetes, Karlsburg, Germany.

Background and aims: DPP-4 (dipeptidyl peptidase-4) inhibition has been reported to increase incretin effects of GIP as well as GLP-1 by prolonging their half life. DPP-4 cleaves GIP into dipeptide and the GIP metabolite GIP (3-42), whereas the GLP-1 (7-36) amide is cleaved to GLP-1 (9-36) amide. Based on studies in man, pig and rat, these peptides are involved in various glucoregulatory processes. We have recently developed a test to differentiate the insulinotropic effects of both peptides in rats. In the present study, we compared the incretin effects of the intact GIP and the GLP-1 (7-36) amide during IVGTT following DPP4 inhibitor administration.
Materials and methods: Groups of catheterized Wistar rats were tested: placebo (P; 0.1 % BSA), DPP4 inhibitor (INH; 30 μmol/kg P32/98, p.o.), incretin in the absence (+P) and presence of INH (+INH) three days apart in a random order. 4.0 nmol/kg GLP-1 ((7-36) amide; Neo MPS; Strasbourg, France) or 2.0 nmol/kg GIP (Probiodrug AG, Halle/Saale, Germany) were injected. Samples for blood glucose (BG) and insulin (I) were taken (-5, 0 min and at 1, 2, 3, 5, 7, 10, 15, 25, 40 and 60 min). INH was given at -20 min, the incretin at -5 min and the IVGTT (0.4 g glucose/kg) commenced at 0 min. G- and I- $AUC_{0\text{-}25min}$, insulinogenic Index iI (I- and G-AUC area quotient (ng/mmol) was selected to measure incretin effects), glucose efflux K_G (min^{-1}; Conard (1959)) was calculated from IVGTT curves. Groups were compared with two-tailed t-test with Bonferroni-Holm correction, a *p<0.05 was considered significant.
Results: INH significantly increased the effects of GIP - G-AUC (P+P: 220±34, INH+P: 185±17, P+GIP: 157±14*, INH+GIP: 156±25* mmol·min/L), I-AUC (P+P: 77±33, INH+P: 60±19, P+GIP: 115±34, INH+GIP: 153±39* ng·min/mL) and Ii (P+P: 0.35±0.17, INH+P: 0.33±0.11, P+GIP: 0.74±0.24*, INH+GIP: 0.99±0.26* ng/mmol) and improved glucose efflux K_G (P+P: 14.5±4.1, INH+P: 14.2±2.4, P+GIP: 19.8±3.1*, INH+GIP: 20.5±5.0* min^{-1}). In contrast, INH attenuated GLP-1 effects - G-AUC (P+P: 226±33, INH+P: 182±20*, P+GLP-1: 183±24, INH+GLP-1: 215±14 mmol·min/L), I-AUC (P+P: 63±28, INH+P: 65±33, P+GLP-1: 125±19*, INH+GLP-1: 106±38 ng·min/mL) and Ii (P+P: 0.27±0.10 , INH+P: 0.35±0.16 , P+GLP-1: 0.70±0.18*, INH+GLP-1: 0.50±0.19

ng/mmol) and declined glucose efflux K_G (P+P: 12.6±5.1, INH+P: 14.5±3.0, P+GLP-1: 14.9±3.1, INH+GLP-1: 11.1±3.7 min^{-1}).
Conclusion: DPP4 inhibition revealed that GLP-1 and GIP differ remarkably in their glucoregulatory actions in healthy rats. These previously unrecognized actions of DPP4 inhibitors may have implications for the use of DPP-4 inhibitors in humans.

GLP-1 and somatostatin are part of a paracrine feedback loop in the isolated perfused porcine ileum
K.R. Hjøllund, S. Pilgaard, J.J. Holst;
Department of Biomedical Sciences, University of Copenhagen, Denmark.

Background and aims: When DPP-4 inhibitors are administrated, peripheral plasma concentrations of intact glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) increase; however, overall (total) incretin secretion appears to be inhibited. The mechanism is unknown, but it has been suggested that increased concentrations of intact GLP-1 may feedback on neighbouring somatostatin-releasing D-cells, which in turn increase their tonic, paracrine restraint on L-cell secretion.
Materials and methods: We examined whether somatostatin (SS) is involved in the local regulation of GLP-1 secretion using the isolated perfused porcine ileum (n=8). In an attempt to break the paracrine circuitry, we infused the GLP-1 receptor antagonist, exendin 9-39 (Ex 9-39)(0.1umol/l), a somatostatin receptor subtype 5 (SSTR5) antagonist (0.1umol/l), or GLP-1(7-36)(1nmol/l), either alone, or in combination with SSTR5 antagonist. Glucagon-like peptide-2 (GLP-2) is co-secreted with GLP-1 from the L-cells, and was therefore used as an index of L-cell secretion.
Results: GLP-1 infusion significantly increased SS secretion from a prestimulatory level of 3.68 ± 0.67 to stimulatory 6.70 ± 1.46 fmol/min (p=0.0195). Moreover, infusion of GLP-1 together with SSTR5 antagonist blocked the inhibitory effect of SS on endogenous L-cell secretion (GLP-2 output increased to 134.7 ± 11.6 % of basal; p=0.0391), resulting in augmented SS output from a prestimulatory level of 3.81 ± 0.64 to stimulatory 9.11 ± 2.34 fmol/min (p=0.0039). Infusion of either SSTR5 antagonist or Ex 9-39 alone resulted in a significant increases L-cell secretion (total GLP-2 output; p=0.0234 and p=0.0391, respectively).
Conclusion: These results indicate that SS regulates the L-cells via SSTR5, and that there is a negative feedback loop between GLP-1 and SS. Additionally we found that GLP-2 secretion was increased by Ex 9-39 alone, indicating that GLP-1 has an indirect tonic inhibitory effect on the L-cells. This feedback mechanism may explain the decreased secretion from the L-cell during DPP-4 inhibitor, even though the concentration of intact GLP-1 plasma concentration increases.

Glucose-dependent insulinotropic polypeptide regulates cytokine expression and lipolysis in human adipocytes
K. Timper[1], J. Grisouard[1], T. Radimerski[1], K. Dembinski[1], R. Peterli[2], H. Zulewski[1], U. Keller[1], M.Y. Donath[3,4], B. Müller[1,5], M. Christ-Crain[1];
[1]Department of Biomedicine, Division of Endocrinology, Diabetes and Clinical Nutrition, Basel, [2]Department of Surgery, St. Claraspital Basel, [3]Clinic of Endocrinology and Diabetes, University Hospital of Zurich, [4]Zurich Center for Integrative Human Physiology, University of Zurich, [5]Internal Medicine, Kantonsspital Aarau, Switzerland.

Background and aims: Serum levels of IL-6, IL-1ß and IL-1 receptor antagonist (IL-1Ra) as well as of glucose-dependent insulinotropic polypeptide (GIP) are increased in obese individuals. The so-called low-inflammatory state in obesity is associated with adipose tissue dysfunction, leading to altered secretion of cytokines, lipolysis and insulin resistance. Inhibition of GIP signalling in rodents protected against diet-induced obesity and insulin resistance. Since GIP is pro-lipolytic in adipocyte-cultures, we hypothesized, that GIP might also be involved in the induction of an inflammatory state in human adipocytes.
Materials and methods: Using a human in vitro model of preadipocyte-derived adipocytes we analyzed the effect of GIP treatment on mRNA expression of IL-6, IL-1ß and IL-1Ra. Human adipocytes were exposed to recombinant human GIP(1-42), the beta subunit of IkappaB kinase (IKK-ß) inhibitor sc-514 and to recombinant human IL-1Ra (rhIL-1Ra). mRNA expression was analyzed by real-time PCR. Glycerol content in the cell culture supernatant was determined as an index of lipolysis.
Results: Treatment of differentiated human adipocytes with GIP from 10pM to 100nM for 1h induced IL-6, IL-1ß and IL-1Ra mRNA expression. Treatment with 1nM GIP maximally increased IL-6 to 4.21±0.28 fold (p<0.001 vs. control) and IL-1ß to 1.64±0.13 fold (p<0.05 vs. control). IL-1Ra mRNA expression was induced to a maximum of 23.5±3.94 fold (p<0.001 vs. control) with 100nM GIP. During time-course experiments with 1nM GIP, IL-6 mRNA expression was acutely increased to 2.55±0.5 fold (p<0.001 vs. control) after 1h. IL-1ß gene expression was constantly increased during 24h with a maximum expression of 1.64±0.13 fold (p<0.001 vs. control) after 4h of 1nM GIP treatment. IL-1RA mRNA expression was upregulated by 4.77±0.5 fold (p<0.001 vs. control) after 2h and reached a maximal increase by 5.2±0.53 fold (p<0.001 vs. control) at 4h. Preincubation with sc-514 (100µM) for 1h inhibited GIP-induced IL-6 expression by 57% (p<0.05 vs. GIP 1nM 1h) and GIP induced IL-1Ra expression by 78% (p<0.01 vs. GIP 1nM 1h), while GIP-induced IL-1ß expression was not inhibited. Preincubation with rhIL-1RA 1µg/ml inhibited GIP-induced IL-6 expression by 68% (p<0.01 vs. GIP 1nM 1h). Treatment with 1nM GIP for 6h in serum free conditions revealed a 1.64±1.37 fold (p<0.01 vs. control) increase of basal glycerol release. Pretreatment with sc-514 (100µM) fully blocked GIP-induced glycerol release (p<0.001 vs. GIP 1nM 6h) while 1µg/ml rhIL-1Ra 1h prior to 1nM GIP reduced GIP-induced lipolysis by 66% (p<0.05 vs. GIP 1nM 6h).
Conclusion: Our findings demonstrate the potential of GIP to induce a pro-inflammatory state with a concomitant anti-inflammatory IL-1Ra response in human adipocytes, leading to lipolysis. The GIP effect on IL-6 and IL-1Ra mRNA expression and lipolysis seems to involve the classical NF-kB pathway and suggests the involvement of an autokrine IL-1ß effect.

Effects of glucagon like Peptide-1 and metformin on the proliferation, apoptosis and function of glucagon like Peptide-1-secreting cells
C. Kappe[1], J.J. Holst[2], C. Patrone[1], Q. Zhang[1], Å. Sjöholm[1];
[1]Department of Clinical Research and Education, Stockholm, Sweden, [2]The Panum Institute, Department of Biomedical Science, Copenhagen, Denmark.

Background and aims: Glucagon-like peptide-1 (GLP-1) is an incretin hormone, secreted from gut L-cells upon nutrient intake, and forms the basis for novel drugs against type 2 diabetes. Secretion of GLP-1 is impaired in type 2 diabetes. Little is known about the influence of antidiabetic drugs on L-cell function and regeneration. The aim of this study was to investigate the effects of GLP-1 and metformin on the proliferation, apoptosis and function of the GLP-1-secreting cells and the mechanisms underlying such effects.
Materials and methods: The GLP-1-secreting cell line GLUTag was cultured in DMEM media. Cell proliferation was evaluated by ^{3}H-thymidine incorporation, MTT-assay and Ki67 staining after a 48 h-incubation with the antidiabetic agents in the presence or absence of the GLP-1 receptor antagonist exendin(9-39). Cellular cAMP production and secretion of GLP-1 from the cells was measured using specific ELISA kits. Apoptosis was evaluated using cell death detection ELISA and caspase-3 activity was measured using caspase-3 activity ELISA kit. The expression of the GLP-1 receptor in GLUTag cells was assessed by Western blotting using anti-GLP-1 receptor antibody.
Results: GLP-1 stimulated proliferation of the GLP-1-secreting GLUTag cells to a similar extent as insulin at low (3 mM), but not high (11 mM), concentrations of glucose. The DPP-IV inhibitor sitagliptin also promoted proliferation of GLUTag cells at high glucose. These cells expressed the GLP-1 receptor as demonstrated by Western blotting. The stimulatory effect of GLP-1 on GLUTag cell proliferation was blocked by pre-treatment with the receptor antagonist Exendin(9-39). However, the cAMP agonist Sp-cAMP[S] suppressed cell proliferation under these conditions. Metformin significantly inhibited proliferation of GLUTag cells but dose-dependently protected the cells from palmitate-induced apoptosis. In contrast, GLP-1 did not influence palmitate-induced apoptosis of the GLUTag cells. In addition, metformin significantly stimulated short-term secretion of GLP-1 from these cells.
Conclusion: The present study shows that GLP-1 stimulated proliferation of GLP-1-secreting cells, an effect that was blocked by a GLP-1 receptor antagonist, indicating a requirement of the GLP-1 receptor for this event. The results suggest that a positive feedback mechanism by GLP-1 may stimulate these cells in an autocrine/paracrine manner. Since serum GLP-1 levels are decreased in type 2 diabetic patients, the mitogenic stimulation of GLP-1-producing cells by GLP-1 and the protective effect of metformin against lipoapoptosis noted here suggests a novel beneficial long term effect of these antidiabetic drugs in clinical practice, *i.e.* by restoring GLP-1 deficiency through enhanced L-cell mass.

GLP-1 inhibits glucagon secretion from human alpha cells by a direct effect

R.D. Ramracheya, C. Ward, F. Abdulkader, M. Shigeto, A. Clark, P. Johnson, M. Braun, P. Rorsman;
OCDEM, University of Oxford, United Kingdom.

Background and aims: Glucagon is secreted from the alpha-cells of the pancreatic islets. Both intrinsic and paracrine mechanisms are involved in the metabolic regulation of glucagon release. Glucagon secretion is also under hormonal control, one of which is glucagon-like peptide 1 (GLP-1). GLP-1 enhances insulin release but most importantly its hypoglycaemic action is amplified by a concomitant suppression of glucagon secretion. Oversecretion of glucagon occurs in type-2 diabetes, exacerbating the hyperglycaemia resulting from the lack of insulin and this constitutes a valuable feature of GLP-1 action. However, the mechanism by which GLP-1 modulates islet glucagon secretion remains unclear. Here we have examined the effects of GLP-1 on glucagon secretion in human pancreatic islets.
Materials and methods: Immunocytochemistry was used to examine expression of GLP-1 receptors in human islet cells. Islet hormone release was measured from intact islets by static incubation. Confocal microscopy was used to investigate the effects of GLP-1 on the spontaneous $[Ca^{2+}]_i$ oscillations at 1 mM glucose to reflect the activity of alpha-cells. Perforated patch whole-cell measurements were used for membrane potential recordings.
Results: Human pancreatic beta- and delta-cells exhibited clear GLP-1 receptor (GLP-1R) immunoreactivity but only ~1% of the alpha-cells showed detectable levels of the receptor. GLP-1 (10 nM) inhibited glucagon secretion elicited by 1 mM glucose (1G; mean±sem as pg/islet/h: 1G: 20.27±4.06; 1G+GLP-1: 10.83±1.96; $p<0.05$). This effect was not associated with any stimulation of insulin secretion (as ng/islet/h; 1G: 0.15±0.02; 1G+GLP-1: 0.18±0.03) but correlated with a ~3-fold stimulation of somatostatin (SST) secretion (as fmol/islet/h: 1G: 0.35±0.08; 1G+GLP-1: 0.63±0.1; $p<0.05$). The inhibitory action of GLP-1 on glucagon secretion was only partially antagonised by the SST receptor antagonist CYN154806 (100 nM) and GLP-1 retained a 35% inhibitory effect (1G: 3.44±0.41; 1G+GLP-1: 1.58±0.15; $p<0.001$; 1G+CYN154806: 3.74±0.76; 1G+CYN154806+GLP-1: 2.36±0.25; $p<0.05$). Effects of GLP-1 and glucose were next compared with forskolin (10 nM) which blocked glucagon secretion by 30% (1G: 15.76±2.99; 1G+forskolin: 11.06±2.16; $p<0.05$). GLP-1 inhibition was mimicked by the P/Q-type Ca^{2+}-channel blocker ω-agatoxin (AGA; 100 nM; 1G: 10.41±1.7; 1G+GLP-1: 3.85±0.86; 1G+AGA: 6.65±0.65). GLP-1 had no effect on the amplitude of the $[Ca^{2+}]_i$ oscillations at 1G (20 alpha-cells in 10 islets; n=6 donors). They were also unaffected by 1 μM insulin (42 alpha-cells from 4 islets; n=2 donors) or 10 μM Zn^{2+} (41 alpha-cells in 5 islets; n=2 donors). In an alpha-cell in an intact islet GLP-1 depolarized the cell by a few mV and reduced the peak voltage of the action potential by ~10 mV.
Conclusion: GLP-1 receptors are expressed at low levels in alpha cells. Blockade of insulin and SST signalling does not affect glucagon inhibition. GLP-1 effects on glucagon secretion can be mimicked by nanomolar concentrations of forskolin. These data suggest that GLP-1 principally acts by a direct effect on human alpha cells

Effects of glucose, GLP-1 and adrenaline on alpha cell electrical activity and glucagon secretion from mouse pancreatic islets

Q. Zhang[1], Y.Z. De Marinis[2], R.D. Ramracheya[1], O. Braha[1], M. Braun[1], P. Rorsman[1];
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom, [2]Department of Clinical Sciences, Malmo, Sweden.

Background and aims: Pancreatic islet α-cells secrete glucagon during hypoglycaemia. Glucagon secretion is suppressed by elevation of glucose concentration and by the incretin hormone GLP-1 but stimulated by the stress hormone adrenaline. Like beta cells, alpha cells generate action potentials to allow influx of Ca2+ which in turn triggers exocytosis of glucagon-containing granules. Several ion channels are involved in this process. Both voltage gated Na+ channels and Ca2+ channels contribute to the upstroke of the action potentials (AP) and K+ channels are involved in repolarisation. Here we have analyzed the mechanism by which glucose, GLP-1 and adrenaline modulate glucagon secretion.
Materials and methods: Static incubation experiments using intact mouse islets were performed to measure glucagon secretion under treatment of different glucose concentrations as well as various reagents. Electrical activity and exocytosis was measured by patch-clamp measurements in alpha cells within intact mouse islets. In membrane potential recordings, alpha cells were identified by its active electrical activity when islets were exposed to 1 mmol/l glucose. In voltage clamp experiments, cells were infused with biocytin and later indentified by immunocytochemistry.
Results: Glucagon secretion is suppressed by 6 mmol/l glucose by ~50%. GLP-1 exerted similar effect while adrenaline stimulated the secretion of glucagon by ~2-fold. Mouse alpha cells exposed to 1 mM glucose fire overshooting APs starting at -51 mV with a peak of +5 mV. Glucose (6 mmol/l) depolarises the interspike voltage by ~4 mV and reduced the peak voltage by 6 mV. GLP-1 (100 nmol/l) did not detectably affect the interspike voltage but reduced spike height by ~2 mV. GLP-1 inhibited N-type Ca2+-channels by a PKA-dependent mechanism. Inhibition of N-type Ca2+-channels using ω-conotoxin mimicked the effects of glucose and GLP-1 on glucagon secretion. Inhibition of N-type Ca2+-channels by ω-conotoxin or GLP-1 inhibited α-cell exocytosis. Blockade of N-type Ca2+-channels reduced action potential amplitude by ~2 mV without affecting the interspike voltage. Adrenaline (10 μmol/l) depolarised the α-cell by ~10 mV and lowered the amplitude of APs by 20 mV. Glucagon secretion enhanced by adrenaline involved L-type Ca2+-channels and the cyclic AMP sensor Epac2.
Conclusion: We propose that glucose and GLP-1-induced suppression of glucagon secretion by inhibition of N-type Ca2+-channel activity. In the case of glucose, this effect is secondary to membrane depolarisation and voltage-dependent inactivation of the N-type Ca2+-channels. GLP-1 directly affects N-type Ca2+-channel gating by an effect not mediated by membrane depolarisation. In both cases, the resultant inhibition of N-type Ca2+-channel activity results in suppression of depolarisation-evoked exocytosis. Adrenaline by-passes this inhibitory effect by activation of Epac2 and L-type Ca2+-channels.

PPAR delta positively regulates GLP-1 production by intestinal endocrine L cells and improves the oral glucose-induced insulin secretion in diabetic obese mice

S. Lestavel[1,2], M. Daoudi[1,2], N. Hennuyer[1,2], M.G. Borland[3], J.M. Peters[3], B. Staels[1,2];
[1]Inserm U1011, Lille, France, [2]Université Lille Nord de France, France, [3]Department Veterinary and Biomedical Sciences, The Pennsylvania State University, USA.

Background and aims: GLP-1 (Glucagon-Like Peptide-1) is an incretin hormone derived from the proglucagon gene transcription product and secreted by the intestinal L cells in response to dietary nutrients. GLP-1 stimulates glucose-dependent insulin secretion and insulin biosynthesis, inhibits glucagon secretion and gastric emptying and reduces food intake. In this study, we examined the regulation of GLP-1 production by PPARdelta/beta (Peroxisome Proliferator-Activated Receptor delta/beta) which is a nuclear receptor reported to improve islet function and to prevent weight gain.
Materials and methods: We used the murine and human L cell lines (respectively GLUtag and NCI-H716) activated or not with the synthetic PPARdelta ligands (GW501516 and GW0742). Wild type and diabetic ob/ob mice were also treated with these compounds.
Results: We show in the L cell lines that in vitro PPARdelta activation induces proglucagon gene expression in a dose and time dependant manner (up to 3 fold with 1μM of GW501516 at 24h) and increases to the same extent glucose and bile acid-induced GLP-1 release. Interestingly, we show that a 15 day oral treatment of wild type and ob/ob mice with GW501516 (once per day at 10 mg/kg) increases (3 fold increase compared to vehicle) GLP-1 secretion at 15 min after orally glucose tolerance test (O-GTT) but not after IP-GTT and that is correlated with the up-regulation of proglucagon gene expression in the ileum (2 fold increase) and the up-regulation of GLP-1 receptor expression in pancreas. In addition, we also observed in vivo and in vitro the positive effect of PPARdelta activation by another agonist GW0742. Moreover, GW501516 treatment in ob/ob mice decreases the basal insulin mRNA expression in the pancreas and basal insulin concentration in the plasma which could reflect the improvement of the glycemic control.
Conclusion: Altogether, these data suggest that the PPARdelta/beta activation potentiates the incretin system that is crucial in regulating postprandial glycemia and that pharmacological targeting of PPARdelta/beta may constitute a promising incretin-based strategy for the treatment of insulin resistance, diabetes and associated metabolic disorders.

Effects of enterically coated, nutrient-containing pellets on glycaemia and incretin hormone release in patients with type 2 diabetes

C.K. Rayner[1,2], J. Ma[1,2], H.L. Checklin[1,2], J.M. Wishart[1,2], J.E. Stevens[1,2], K.L. Jones[1,2], M. Horowitz[1,2], J.H. Meyer[1,3];
[1]Discipline of Medicine, University of Adelaide, Royal Adelaide Hospital, Australia, [2]Centre of Clinical Research Excellence in Nutritional Physiology, University of Adelaide, Australia, [3]Meyer Nutriceuticals, Santa Monica, USA.

Background and aims: In principle, delivery of a small amount of nutrient to a long length of distal gut could be a potent stimulus for release of glucagon-like peptide-1 (GLP-1), with consequent improvements in glycaemic responses to subsequent meals. We evaluated the effects of enteric coated pellets designed for continuing release of small amounts of lauric acid along ileum and colon, on GLP-1 secretion and the glycaemic response, after both breakfast and a subsequent lunch.
Materials and methods: Ten patients with well controlled type 2 diabetes (glycated haemoglobin 5.9 ± 0.2 %), managed by diet alone, were studied on two separate days. On each study day, they ingested either 10 g active pellets (47 % lauric acid by weight, or ~40 kcal) or placebo pellets at T = 0 min during breakfast (71 g carbohydrate, 4.3 g protein, 12 g fat, 415 kcal). A second meal (lunch; 89 g carbohydrate, 29 g protein, 26 g fat, 708 kcal) was consumed at T = 240 min. Blood was sampled for measurement of blood glucose, serum insulin, and plasma total GLP-1 and glucose-dependent insulinotropic polypeptide (GIP).
Results: Data are shown as mean ± standard error. After active pellets, blood glucose concentrations were lower, and plasma GLP-1 concentrations higher, than after placebo, following both breakfast and lunch (*P < 0.05 in the figure). In contrast, the rises in insulin and GIP after breakfast and lunch did not differ between active pellets and placebo.
Conclusion: Enteric coated pellets which sustain release of lauric acid along distal small intestine and colon diminish the glycaemic response to both breakfast and lunch in type 2 diabetes, associated with stimulation of GLP-1, establishing that exposure of the distal gut to a small quantity of nutrient can have substantial effects on GLP-1 release and hence glycaemic control.

Degradation of GIP but not of GLP-1 is reduced after protein ingestion in obese subjects

O. Lindgren[1], J. Vikman[1], C.F. Deacon[2], R.D. Carr[3], J.J. Holst[2], B. Ahrén[1];
[1]Department of clinical sciences, Lund University, Sweden, [2]Department of Biomedical Sciences, Copenhagen University, Denmark, [3]Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and aims: The incretin hormones, glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) are released after meal ingestion and potentiate glucose-stimulated insulin secretion. Both hormones are rapidly degraded by the enzyme DPP-4 (dipeptidyl peptidase 4). This major site of degradation is thought to be the gut wall, where we previously showed in animal studies that DPP-4 activity varies depending on macronutrient ingestion, being reduced by protein. We previously showed that secretion and metabolism of the incretin hormones after mixed meal and oral glucose is different in obese versus lean subjects. Thus, GLP-1 but not GIP secretion is lower in obesity after meal ingestion and oral glucose, whereas GIP but not GLP-1 metabolism is increased in obesity after meal ingestion. In this study, we have proceeded and examined GIP and GLP-1 secretion and metabolism after oral ingestion of pure protein in lean versus obese subjects.
Materials and methods: The study was undertaken in healthy male human volunteers that were either lean (BMI 20-25kg/m^2; n=12) or obese (BMI 30-35kg/m^2; n=12). After an overnight fast, the subjects at three different occasions consumed 2.22g protein mix (Promax protein 85^R)/kg b wt. Blood samples were collected before and up to five hours after intake of each macronutrient for measurements of total(t) and intact(i) GLP-1 and GIP. Hormone responses were assessed as suprabasal AUC300 over the entire 300 minutes study period.
Results: Both GIP and GLP-1 secretion increased following ingestion of protein, as reflected by increased concentrations of tGLP-1 and tGIP. Whereas the secretion of GIP was markedly lower in the obese subjects (AUC_{tGIP} 10.0±2.8 vs. 18.4±2.7 pmol/l; P=0.046), there was no difference between obese and lean subjects in AUC_{iGIP}. This suggests that degradation of GIP is reduced after protein ingestion in obese subjects. In contrast, GLP-1 did not show any differences between lean and obese after protein ingestion for either

intact or total levels, suggesting that secretion and degradation of GLP-1 are not affected by obesity.
Conclusion: Our results show a reduced GIP but a normal GLP-1 secretion after protein ingestion in obese subjects in association with a reduced rate of GIP degradation but a normal degree of GLP-1 degradation. This resulted in normal concentrations of intact forms of the two incretins after protein ingestion in obesity. The reduced degradation of GIP after protein ingestion in obese subjects may be the result of decreased DPP-4 activity after protein in the proximal portion of the gut.

Short-term intervention with steroid hormone, relative physical inactivity and high calorie diet in healthy subjects results in increased postprandial GIP and glucagon responses
F.K. Knop[1], K.B. Hansen[2,3], J.I. Bagger[1], J.J. Holst[3], T. Vilsbøll[1];
[1]Department of Internal Medicine F, Gentofte Hospital, University of Copenhagen, [2]Department of Clinical Physiology, Glostrup Hospital, University of Copenhagen, [3]Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark.

Background and aims: The incretin hormone glucose-dependent insulinotropic polypeptide (GIP) has been proposed as a link between consumption of high fat diets and the development of obesity, insulin resistance, hyperinsulinaemia and type 2 diabetes mellitus (T2DM). In obese subjects the GIP response to a mixed meal is reported to be increased perhaps contributing to postprandial hyperinsulinaemia. Additionally GIP has been shown to stimulate glucagon secretion. Postprandial responses of the other incretin hormone glucagon-like peptide-1 (GLP-1) has been reported to be decreased in obese individuals as well as in patients with T2DM. In the present study we evaluated the impact of disruption of insulin sensitivity on postprandial GIP, GLP-1 and glucagon responses in healthy young male subjects without any risk factors for diabetes.
Materials and methods: Postprandial GIP, GLP-1 and glucagon responses were measured using a 520 kcal-liquid meal test (58 g carbohydrate, 28 g fat and 10 g protein) in 10 healthy Caucasian male subjects without family history of diabetes (age: 23.9±3.1 years (mean±SD); BMI: 24.1±1.7 kg/m^2; fasting plasma glucose: 4.9±0.3 mM, HbA_1c: 5.4±0.1%) before and after induction of insulin resistance using high calorie diet, relative physical inactivity and administration of prednisolone (37.5 mg/day) for 10 days.
Results: The intervention had a significant impact on insulin resistance according to the homeostatic model assessment (1.4±0.1 *vs.* 2.3±0.4, p=0.02) without affecting body weight. In line with this, fasting insulin levels (36±3 *vs.* 61±6 pM, p=0.03) and insulin responses (as assessed by AUC) increased following the intervention (30±6 *vs.* 59±16 nM·4h, p=0.02). The impaired insulin sensitivity had no impact on postprandial GLP-1 responses (1.5±1 *vs.* 2.0±1 nM·4h, p=0.56), but postprandial GIP responses rose significantly following induction of insulin resistance (10.6±1.3 *vs.* 14.1±1.5 nM·4h, p=0.03) as well as postprandial glucagon responses (1.6±1.5 *vs.* 2.4±3.2 nM·4h, p=0.03).
Conclusion: Our data show that induction of insulin resistance using prednisolone, high calorie diet and relative physical inactivity results in increased postprandial GIP responses suggesting that increased GIP secretion observed in conditions characterised by insulin resistance may occur as a consequence of insulin resistance rather than being a primary pathogenetic trait. Additionally, our data suggest that hyperglucagonaemia (observed in obese individuals with type 2 diabetes) may be a consequence of insulin resistance, while insulin resistance not seems to be directly responsible for the reduced postprandial GLP-1 responses observed in individuals with type 2 diabetes.

The incretin effect is apparent after lipid challenge in healthy humans
B. Ahrén[1], O. Lindgren[1], J. Vikman[1], C.F. Deacon[2], J.J. Holst[2], G. Pacini[3], A. Mari[3];
[1]Lund University, Sweden, [2]Copenhagen University, Denmark, [3]ISIB.CNR, Padua, Italy.

Background and aims: It is well known that oral glucose gives rise to a greater insulin response than an isoglycaemic intravenous (iv) glucose infusion, due to the incretin effect. We examined whether an incretin effect exists also after lipid ingestion.
Materials and methods: After an overnight fast, 12 healthy male volunteers (age 20-30 years; BMI 20-25 kg/m^2) received lipids (intralipid^R) orally (0.6 g/kg) or iv (infusion rate min 0-30 0.15g/min, min 30-60 0.30g/min and min 60-90 0.45g/min, designed to mimic plasma triglyceride (TG) responses to the oral load). Blood samples were taken over 300 min for analysis of TG, glucose, insulin, C-peptide and intact and total concentrations of glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP).
Results: Plasma glucose did not rise during lipid administration, whereas plasma TG levels rose similarly during oral and iv lipid (peak at 180 min of 1.0±0.2 mmol/l for both). Plasma insulin and C-peptide were unchanged during iv lipid but rose after oral lipid, the difference being largest during the first 60 min. Suprabasal 0-60 min AUC for insulin was 0.46±0.10 nmol/lx60 min after oral lipid vs. -0.11±0.14 after iv lipid (P=0.03); corresponding values for C-peptide were 2.45±0.45 vs. 0.43±0.32 nmol/lx60 min (P=0.001). Figure (left panel) shows the insulin secretory rate (ISR) during the 300 min tests and (right panel) the ratio of ISR after oral vs. iv lipid as estimated from C-peptide data, illustrating the larger insulin secretory response to oral vs iv lipid with matching TG levels. Plasma intact and total GLP-1 and GIP were unchanged during iv but rose after oral lipid. Suprabasal 0-60 min intact GLP-1 was 243±53 pmol/lx60 min after oral lipid vs. -9±5 after iv lipid (P<0.001); corresponding values for intact GIP were 302±118 vs. 9±53 pmol/lx60 min; P=0.031). Suprabasal 60 min AUC for ISR correlated to corresponding AUC for both intact GLP-1 (r=0.42; P=0.043) and intact GIP (r=0.42; P=0.047).
Conclusion: Oral vs iv lipid administration to matching TG levels reveals that oral lipid elicits a clear incretin effect with a pronounced stimulation of insulin secretion during the first 60 min. Since oral lipid as well stimulates the release of the two incretins and the increase in intact (insulinotropic) GLP-1 and GIP correlates with insulin secretion, we conclude that an incretin effect induced by the classical incretin hormones also exists after oral lipid ingestion in healthy humans.

Effect of GLP-1 and exendin-4 treatment on glucose and fat metabolism, in obese state

P. Moreno, B. Nuche-Berenguer, I. Gutiérrez-Rojas, A. Acitores, I. Ramos-Álvarez, N. González, I. Valverde, M.L. Villanueva-Peñacarrillo;
Metabolism, Nutrition & Hormones, IIS-Fundación Jiménez Díaz, Madrid, Spain.

Background and aims: Obesity is often associated with hypertension, cardiovascular disease and diabetes. GLP-1, incretin with insulin-independent antidiabetic actions, and its homologous exendine-4, both have shown positive effects upon the glucose metabolism of extrapancreatic tissues participating in the hexose homeostasis. Here we studied the effect of GLP-1 and Ex-4 on GLUT-4 expression and other parameters, in fat and muscle of an obesity (Ob) rat model, compared to normal (N).
Materials and methods: Ob was developed in male Wistar rats by chronic feeding -5 weeks- with a daily intake of standard chow combined with a "cafeteria diet" (65 % energy from lipids). The N group was fed with standard chow and water *ad libitum* (8 % energy as fat). Although weight was not different between N and Ob, the Ob model showed fasting plasma glucose, triglycerides (153±13 mg/dl, n=11) and cholesterol (92±4 mg/dl, n=12) higher than normal (overall mean: 37±5 % Δ N-rats, $p<0.02$); no significant differences with N were detected in insulin or GLP-1 -by RIA-. Ob and N were 3-days treated -through an osmotic pump- with saline (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1nmol/kg/h). Blood samples were taken before and by the end of the treatment for plasma measurements. In epididimal fat and *soleous* muscles, we studied: GLUT-4 expression -mRNA by RT-PCR, and protein by Western blot-, isolated adipocytes glucose transport (GT) -2-deoxi-D-[1,2-^{3}H]glucose uptake- and muscle glycogen synthase *a* activity (GS*a*) -UDP-glucose into glycogen-.
Results: In muscle of Ob (n=5-7 rats), GLUT-4-protein was lower than in N (71±4 % N-control, $p<0.01$) while mRNA was higher (1.81±0.04 times N-control, $p<0.001$); GLP-1 did not modify mRNA, but increased the protein, to a value (180±14 % Ob-control, $p<0.01$) even higher (128±7 % N-control, $p<0.02$) than that in N (100±13 % N-control, n=6); Ex-4, like GLP-1, failed to modify mRNA, but stimulated the GLUT-4-protein (129±6 % Ob-control, $p<0.05$) to N levels (92±4 % N-control). GS*a* in Ob (1.30±0.16 U/g protein) was lower ($p<0.001$) than in N; GLP-1 did not affect the GS*a*, while Ex-4 induced a clear increase (175±20 Ob-control, $p<0.02$) toward normalization; no apparent effect was detected in N after GLP-1 or Ex-4. In fat of Ob (n=5-9), GLUT-4-mRNA was lower than normal (0.39±0.05 times N-control, $p<0.001$), without differences in the protein; either GLP-1 or Ex-4 reduced GLUT-4-mRNA even further (GLP-1: 0.29±0.05 times Ob-control; Ex-4: 0.65±0.15; both $p<0.01$), as previously observed in N rats; both GLP-1 and Ex-4 exerted a slight but clear increase in GLUT-4-protein (137±9 % Ob-control and 118±5 %, respectively, both $p<0.02$). GT in Ob (6.7±0.7 fmol/10^5 cells) was lower ($p<0.001$) than in N (15.1±1.6 fmol/10^5 cells); GLP-1 and Ex-4 increased the value (159±10 % Ob-control and 178±18 %, respectively, both $p<0.01$) toward normalization (overall mean: 74±8 % N-control). In Ob, Ex-4 highly reduced to normalization the triglycerides (86±3 mg/dl, $p<0.01$ *vs* Ob-control) and cholesterol values (75±3 mg/dl, $p<0.01$ *vs* Ob-control), while GLP-1 only decreased triglycerides to normalization (103±9 mg/dl, $p<0.05$ *vs* Ob-control).
Conclusion: In obese state, both GLP-1 and Ex-4 could exert a beneficial effect on its deleterious glucose metabolism, perhaps by their increasing action upon the muscle and fat glucostransporter translation process, together with a normalizing effect on the impaired lipid metabolism.

The separate and combined impact of the intestinal hormones GIP, GLP-1 and GLP-2 on glucagon secretion in type 2 diabetes

A. Lund[1,2], T. Vilsbøll[1], J.I. Bagger[1], J.J. Holst[2], F.K. Knop[1];
[1]Department of Internal Medicine F, Gentofte Hospital, University of Copenhagen, Hellerup, [2]Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark.

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with reduced suppression of glucagon during oral glucose tolerance test (OGTT) whereas isoglycaemic intravenous (*iv*) glucose infusion (IIGI) results in normal glucagon suppression in these patients. We aimed to evaluate the role of the intestinal hormones glucose-dependent insulinotropic polypeptide (GIP), glucagon-like peptide-1 (GLP-1) and glucagon-like peptide-2 (GLP-2) in this discrepancy.
Materials and methods: Glucagon responses were measured during a 3-hour 50 g-OGTT (day a) and a corresponding IIGI (day b) in 10 patients with T2DM (age (mean±SEM): 51±3 years; BMI: 33±2 kg/m^2; HbA_1c: 6.5±0.2%). During four additional IIGIs, GIP (day c), GLP-1 (day d), GLP-2 (day e) and a combination of the three intestinal hormones (day f), respectively, were infused intravenously to mimic postprandial responses.
Results: Isoglycaemia during all six study days was obtained. As expected, no suppression of glucagon occurred during the initial phase of the OGTT, whereas significant ($p<0.05$) suppression of glucagon during the first 30 minutes of the IIGI (day b) was observed. As illustrated in Fig. 1, the glucagon response during the IIGI+GIP+GLP-1+GLP-2 (day f) equalled the inappropriate glucagon response to OGTT (p=NS). The separate GIP infusion (day d) elicited significant hypersecretion of glucagon, whereas GLP-1 infusion (day d) resulted in potentiation of glucagon suppression during IIGI. IIGI+GLP-2 infusion resulted in a glucagon response in the mid-range between the inappropriate glucagon response to OGTT and the preserved suppression during IIGI.
Conclusion: Our results indicate that the intestinal hormones, GIP, GLP-1 and GLP-2, may play a role in the inappropriate glucagon response to orally ingested glucose in T2DM with GIP acting as a strong glucagonotropic substance.

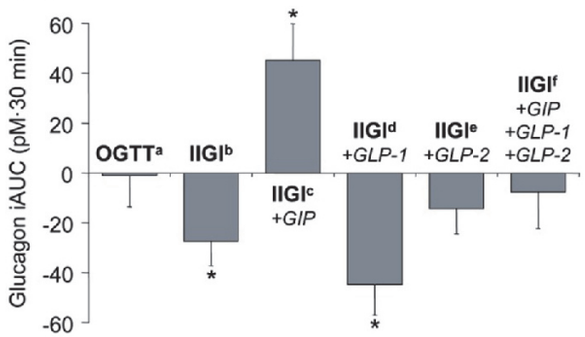

Figure 1. Initial glucagon responses following OGTT and IIGIs in patients with T2DM expressed as incremental AUCs (mean±SEM). Asterisks indicate significant difference ($p<0.05$) from 0.

The contribution of GLP-1 to the enteroinsulinar axis in type 2 diabetes mellitus

J. Schirra, L. Carneiro, M. Nicolaus, A. Derani, B. Aulinger, B. Göke;
Department of Internal Medicine II, Campus Großhadern, University of Munich, Germany.

Background: The gut born hormones GLP-1 and GIP augment glucose-dependently the postprandial (PP) insulin release from the pancreatic B-cell, mediating the so-called incretin effect which constitutes the difference between the postprandial (PP) and the isoglycemic fasting insulin response. In addition, GLP-1 reduces glucagon. In T2DM, the incretin effect is reduced and plasma glucagon increased. A defect of the GIP action has been suggested in T2DM. However, the contribution of either hormone in T2DM is not known.
Aim: To analyze the contribution of endogenous GLP-1, we examined the effect of a duodenally perfused meal on pancreatic insulin and glucagon secretion using the specific GLP-1 receptor antagonist exendin(9-39) (Ex-9).
Methods: 12 patients with T2DM (age 60±2, BMI 28.1±1.2, HbA1c 6.4±0.3) and 12 healthy subjects (HS) participated in 3 study days in random order. Plasma insulin and glucagon concentrations were measured during a 3 hour hyperglycemic clamp at 180mg/dl using IV glucose. 30 min prior the clamps, a duodenal meal perfusion (2.03 kcal/min, 77% lipid, 23% glucose) was initiated and continued throughout the study on 2 days. This was accompanied by IV infusion of Ex-9 (600 pmol/kg/min) or saline, respectively. A third day with duodenal perfusion of saline served as isoglycemic fasting control (IF) to calculate the incretin effect. The acute insulin response (AIR) to hyperglycemia and the sustained responses of plasma insulin (SIR) and glucagon (SGR) were calculated during the first 10min and between 60 and 120min of the hyperglycemic clamp as incremental AUC (see table).
Results: In HS, AIR and SIR during the duodenal meal (PP) were markedly increased compared to isoglycemic fasting conditions (IF) corresponding to an incretin effect of 0.34±0.1 and 5.1±0.8 mU/ml*min, respectively. In T2DM,

both AIR and SIR were significantly lower compared to HS and the incretin effect was significantly reduced (0.13±0.04 and 1.9±0.7 mU/ml*min, p<0.05 vs HS). Ex-9 reduced PP AIR and SIR both in HS and T2DM. Also with Ex-9, PP AIR and SIR remained significantly elevated compared to IF both in HS and T2DM corresponding to a GLP-1 independent incretin effect in T2DM of 0.08±0.03 (AIR) and 0.60±0.25 (SIR) mU/ml*min, thus representing 79% and 51% of PP insulin response, respectively. Plasma glucagon concentrations were markedly elevated in T2DM. Ex-9 significantly increased SGR in both, HS and T2DM.

Conclusion: Both the acute and sustained postprandial response to hyperglycemia is largely mediated by gut hormones. This incretin effect is clearly reduced in T2DM compared to HS. However, GLP-1 and non-GLP-1 incretins contribute equally to the incretin effect both in HS and T2DM. We suggest GIP to account for the remaining incretin effect also in T2DM. As in HS endogenous GLP-1 contributes largely to the postprandial suppression of plasma glucagon. We conclude that although pancreatic islet cell secretion is disturbed in T2DM, the enteroinsulinar axis seems to be intact also in T2DM.

Insulin resistance and glucose intolerance independently reduce the incretin effect via a beta cell defect

D.H. Jensen[1], K. Aaboe[2], A. Voelund[3], J.E. Henriksen[4], J.J. Holst[5], S. Madsbad[6], T. Krarup[1];
[1]Endocrinology, Bispebjerg University Hospital, Copenhagen, [2]Endocrinology, Herlev University Hospital, [3]Endocrinology, Bispebjerg Hospital, Copenhagen, [4]Endocrinology, Odense University Hospital, [5]Department of Biomedical Sciences, Panum Institute, Copenhagen, [6]Endocrinology, Hvidovre University Hospital, Denmark.

Background and aims: The incretin effect is impaired in type 2 diabetes. We wanted to evaluate the separate impact of insulin resistance and glucose intolerance on the incretin effect and whether changes in the incretin effect were associated with β-cell defects.

Materials and methods: 21 healthy 1st degree relatives to type 2 diabetes patients with normal glucose tolerance underwent a 75g OGTT on day 1 and an isoglycemic i.v. glucose test on day 2. The two tests were performed before and after 5 days treatment with 2mg dexamethasone bid. Insulin, C-peptide, GIP and GLP-1 were measured during the 4 tests. The incretin effect was estimated by relating the incremental insulin response during the OGTT to the incremental insulin response during the i.v. glucose infusion. Furthermore, the insulin secretion rates during the i.v. glucose infusions were plotted against ambient P-glucose, and the slopes of these linear relations were used as an index of the β-cell glucose sensitivity, which is known to be impaired already in the early stages of type 2 diabetes. To relate the β-cell glucose sensitivity to the ambient insulin resistance the disposition index was calculated by multiplying β-cell glucose sensitivity with $1/HOMA_{IR}$.

Results: The dexamethasone treatment increased insulin resistance in all 21 subjects, and 11 subjects in addition to insulin resistance also developed glucose intolerance (IGT) (10 subjects remained glucose tolerant (NGT)). The incretin effect was in the NGT and IGT group 71±3.2 and 67±4.6% before and 58±5.2 and 32±8.8% after treatment, respectively. There was no difference in the incretin effect between groups at baseline but a significant difference after treatment (P < 0.05). A multiple regression analysis of pooled data from the two groups related the changes in incretin effect (Δincretin effect) to changes in insulin resistance ($\Delta HOMA_{IR}$) and glucose tolerance (delta 2-hour P-glucose during OGTT, ΔPG_{120}). ΔPG_{120} and $\Delta HOMA_{IR}$ were negatively and independently correlated with Δincretin effect (P < 0.05), and accounted for 45% of the overall variation in Δincretin effect. The disposition index was 1.7±0.20 and 1.4±0.17 pmol kg^{-1} min^{-1} mM^{-1} in the NGT and IGT groups, respectively (P = NS). After the dexamethasone treatment this index was 1.3±0.19 in the NGT group and 0.9±0.12 pmol kg^{-1} min^{-1} mM^{-1} in the IGT group, respectively (P < 0.05). The reduction in the disposition index in the NGT group was not significant (P =NS). Responses of GLP-1 and GIP did not differ between groups before or after dexamethasone during the OGTT.

Conclusion: Insulin resistance and glucose intolerance contribute independently to the reduced incretin effect seen in type 2 diabetes. In addition we find that the incretin effect is reduced very early in NGT insulin resistant people, before the β-cell sensitivity to i.v. glucose is affected, and deteriorates further when β-cell function declines in people with IGT. This points to an early, specific β-cell defect in the action of the incretin hormones before the development of overt type 2 diabetes.

GIP controls human core circadian genes indicating an integrative role in food-regulated metabolism

Ö. Gögebakan[1], M.A. Osterhoff[1], F. Isken[1], N.N. Rudovich[1], K.-N. Fernaz[1], M. Nauck[2], A.F.H. Pfeiffer[1];
[1]Clinical Nutrition, DIfE, Rehbrücke, [2]Diabeteszentrum, Bad Lauterberg, Germany.

Background and aims: Adaptation of metabolism to circadian rhythms is critical for its proper function. Rhythmically expressed peripheral clock genes are regulated by food intake but detailed mechanisms are unknown. We investigated the role of the food induced hormones, GIP, insulin and glucose on expression of core circadian genes in human adipose tissue.

Materials and methods: 17 overweight healthy humans (BMI: 28-40 kg/m2, age: 30-65 y) with normal glucose tolerance were infused with placebo or GIP in physiological doses for 4h i.v. either alone, or during euglycemic or hyperglycemic hyperinsulinemic clamps. Biopsies were taken from subcutaneous adipose tissue before and after treatment. Total RNA was isolated from all biopsies and transcribed into cDNA. Expression patterns of circadian genes were analysed by hybridisation to a total number 100 Agilent 60-mer Whole Human Genome (4x44K) single-color DNA microarrays and results confirmed by quantitative RT-PCR. Statistical analysis of microarray data was performed with Agilent GeneSpring GX software.

Results: The expression of REV ERBalpha (NR1D1) was regulted during the 4 h treatment even under placebo conditions and decreased significantly about 4 fold. The expression of other circadian genes like PER2, PER3, TEF and DBP did not change significantly. Neither insulin nor glucose affected clock gene expression in euglycemic or hyperglycemic hyperinsulinemic clamps. However, GIP either alone or combined with insulin and glucose, significantly enhanced the circadian decrease of the core clock genes REV ERBalpha 6.5 - 9 fold as well as PER2, PER3 and the clock output genes TEF and DBP between 1.5 - 2.5 fold. These genes were among the most significantly GIP-regulated genes even after correction for multiple testing (Benjamini Hochberg). Additional correlation analysis showed a disintegration of clock gene correlations among each other as a result to GIP administration. The decrease was not reproduced in a mouse model upon treatment with GIP at different circadian time points pointing to species specific differences.

Conclusion: We identify GIP as a powerful regulator of the core clock gene machinery in human adipose tissue in vivo which provides the missing link from food intake to peripheral clock gene regulation. Since i.e. REV ERBalpha is involved in regulation of glucose, lipid and cholesterol metabolism, fat cell differentiation and inflammatory processes, the disruption of circadian rhythms by GIP may explain its obesogenic and fatty liver inducing properties.

Dynamic beta cell function in young type 2 diabetes patients (15-34 years) in the Diabetes Incidence Study in Sweden register

M. Sjostrand[1], H.J. Arnqvist[2], J.W. Eriksson[1], S. Gudbjörnsdottir[3], S. Lindmark[4], M. Landin-Olsson[5], L. Nyström[4], M.K. Svensson[3], P. Adolfsson[1], K. Arneklev[1], J. Bolinder[6];
[1]Early Phase Development, R&D, AstraZeneca, Mölndal, [2]Linköping University Hospital, [3]Sahlgrenska University Hospital, Göteborg, [4]Umeå University, [5]Lund University Hospital, [6]Karolinska University Hospital, Stockholm, Sweden.

Background and aims: Simple methods for evaluation of dynamic beta-cell function in epidemiological and clinical studies of type 2 diabetic patients (T2D) are needed. The first phase insulin response after intravenous (iv) glucose is diminished whereas the insulin response after non-glucose stimulation, i.e. iv arginine is less dependent on prevailing glucose levels. The objective of this study was to compare these methods for assessment of dynamic beta-cell function in young T2D with different disease duration and treatments.
Materials and methods: 54 T2D patients from the Diabetes Incidence Study in Sweden (DISS) and 23 healthy controls; group-wise matched for age (35±5.4 vs 40±5.8 years), sex (M/F 33/21 vs. 12/11) and BMI (33±5.7 vs. 33±4.5 kg/m^2) were included in a cross-sectional study. Beta-cell function was assessed by iv pulses of arginine 5g followed after 30 min by iv glucose 0.3g/kg. The acute insulin and c-peptide response to arginine (AIR_{arg} and $A_{c\text{-}pep}R_{arg}$) and to glucose (AIR_{glu} and $A_{c\text{-}pep}R_{glu}$) was calculated as the mean of the three highest levels of insulin and c-peptide obtained during 5 minutes minus the plasma level of insulin and c-peptide at baseline.
Results: Fasting p-glucose at baseline was 7.5 mmol/L in T2D and 5.5 mmol/L in healthy controls. AIR_{glu} and $A_{c\text{-}pep}R_{glu}$ were reduced approx 90% in T2D and AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ were reduced approx 30% in T2D (7.6±24 vs.93±60, p<0.05; 0.5±1.3 vs. 4.2±2.4, p<0.05 and 51±45 vs.72±43, p= 0.07 and 2.4±1.6 vs 3.2±1.4, p=0.06)(compared to the healthy controls). AIR_{glu} and $A_{c\text{-}pep}R_{glu}$ but not AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ responses was negatively correlated with fasting p-glucose at baseline (r= -0.52, r=-0.48 p<0.05 and r=0.10 and r=0.15, ns). AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ disciminated patients with different disease duration better than AIR_{glu} and $A_{c\text{-}pep}R_{glu}$ as displayed in Table. In addition, AIR_{glu} and $A_{c\text{-}pep}R_{glu}$ was higher in the diet-treated group compared to other treatments, while AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ were decreased in insulin-treated patients compared to other treatments groups (see Table).
Conclusion: AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ were less reduced than AIR_{glu} and $A_{c\text{-}pep}R_{glu}$ in young type 2 diabetic patients and discriminated better between groups with different disease duration. AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ was also less dependent on baseline plasma glucose levels. AIR_{arg} and $A_{c\text{-}pep}R_{arg}$ may be used epidemiological and clinical studies to select patients suitable for drugs affecting dynamic beta-cell function.

The graded glucose infusion is comparable to the hyperglycaemic clamp as a tool for measurement of glucose-dependent insulin secretion

D.E. Kelley[1], R.R. Shankar[2], B. Keymeulen[3], L. Mixson[4], D.L. Mixson[5], C. Chung[5], E. Vandemeulebroucke[3], M. DeSmet[6], C. Cilissen[6], G.A. Herman[7], C.R. Beals[5], H.O. Steinberg[2], S.S. Shankar[5];
[1]Diabetes and Obesity, Merck Research Laboratories, Rahway, USA, [2]Clinical Research-Metabolism, Merck Research Laboratories, Rahway, USA, [3]Metabolism, UZ Brussels, Belgium, [4]BARDS, Merck Research Laboratories, Rahway, USA, [5]Experimental Medicine, Merck Research Laboratories, Rahway, USA [6]Clinical Pharmacology, Merck Sharpe and Dohme, Brussels, Belgium, [7]Early Stage Development, Merck Research Laboratories, Rahway, USA.

Background and aims: The hyperglycemic clamp (HGC), considered the gold standard method for measurement of glucose-dependent insulin secretion (GDIS) is technically resource intensive. In contrast, the Graded Glucose Infusion (GGI) is a simpler, but less well-characterized method. We tested the hypothesis that the GGI is comparable to the HGC as a tool to measure changes in GDIS, by performing a randomized, double-blind, placebo-controlled experiment that directly compared the GGI and the HGC, using exenatide as a probe.
Materials and methods: Following an overnight fast, 18 non-obese healthy subjects (age 29 ± 8 yrs, BMI 23.5 ± 2.3 kg/m^2, basal fasting glucose 4.50 ± 0.24 mmol/L) received 5µg exenatide s/c or matched placebo, immediately prior to the procedures. Each subject underwent a GGI (glucose infusion rates (GIR) of 2, 4, 6 and 12mg/kg/min, 40 minute periods each) and a HGC (glycemia maintained at 11.1 mmol/L for 120 minutes; steady-state (SS) 90 to 120 minutes) on separate days, in a randomized crossover design.
Results: Data are presented as Mean ± SEM, exenatide vs placebo. HGC: At matched SS plasma glucose (10.80 ± 0.11 vs 10.71 ± 0.13 mmol/L), significant differences (p<0.001 for all comparisons) were observed in GIR (1.05 ± 0.09 vs 0.45 ± 0.07 mmol/kg/min), plasma insulin (4111.44 ± 303.50 vs 322.94 ± 225.02 pmol/L), C-peptide (9.76 ± 0.59 vs 2.06 ± 0.47 nmol/L), and insulin secretion rates (ISR) (1398.6 ± 99.9 vs 333.0 ± 66.6 pmol/min). GGI: At matched GIR, significant (p<0.001 for all comparisons) differences were observed in ambient plasma glucose levels (G) (7.72 ± 0.59 vs 13.19 ± 0.59 mmol/L), ISR (1465.2 ± 166.5 vs 699.3 ±166.5 pmol/min), and Φ (slope of ISR/G: 4.2 ± 0.17 vs 1.89 ± 0.15). Both methods were compared using the only common end-point, the ratio of ISR to G. The ISR/G for exenatide in the GGI was comparable to that in the HGC (2.95 ± 0.29 vs 2.14 ± 0.15 respectively). The GGI was operationally simpler than the HGC.
Conclusion: This study demonstrates for the first time in a head to head setting, that the GGI is comparable to the HGC in its ability to detect clinically relevant changes in GDIS, while being less resource intensive. Our data indicate that the GGI is a sensitive, reliable and feasible tool for measurement of GDIS effects in healthy subjects.

Acute insulin (AIR, µU/ml) and c-peptide(Ac-pepR, nmol/L) responses after iv glucose and iv arginine

A novel tool to measure changes in glucose-dependent insulin secretion in healthy subjects

S.S. Shankar[1], R.R. Shankar[1], L. Mixson[2], D.L. Miller[1], N. Handa[3], M. Cross[4], G.A. Herman[5], C.R. Beals[1], H.O. Steinberg[6], D.E. Kelley[7]; [1]Experimental Medicine, Merck Research Laboratories, Rahway, USA, [2]BARDS, Merck Research Laboratories, Rahway, USA, [3]Merck Sharpe and Dohme, Gurgaon, India, [4]Veeda Research Inc., Ahmedabad, India, [5]Early Stage Development, Merck Research Laboratories, Rahway, USA, [6]Clinical Research-Metabolism, Merck Research Laboratories, Rahway, USA, [7]Diabetes and Obesity, Merck Research Laboratories, Rahway, USA.

Background and aims: The Meal Tolerance Test (MTT) can detect changes in prandial glucose-dependent insulin secretion (GDIS) in Type 2 Diabetes Mellitus (T2DM) subjects; however, it is less suitable as a tool in healthy volunteers (HV), where effect sizes are small, and variability high. We hypothesized that changes in GDIS can be detected in HV, if the MTT is conducted in a milieu simulating the hyperglycemia of T2DM. We tested the hypothesis by performing a randomized, double-blind, placebo controlled, crossover study that measured GDIS effects of the DPP4 inhibitor sitagliptin, in the setting of a MTT superimposed on stable hyperglycemia achieved by a hyperglycemic clamp (HGC) (HGC-MTT).
Materials and methods: Following an overnight fast, and a single dose of sitagliptin 100mg or matched placebo, 12 healthy non-obese subjects (age 27 ± 6 yrs., BMI 20.5 ± 1.3 kg/m^2) underwent a HGC at target glycemia of 8.9 mmol/L for 370 minutes (mins.); a standardized liquid meal was administered at 180 mins, and consumed over 10 mins.
Results: Data are presented as Mean ± SEM, sitagliptin vs placebo. Premeal (120-180mins.): At matched plasma glucose (8.79 ± 0.05 vs 8.95 ± 0.06 mmol/L), significant ($p<0.001$ for all between group comparisons) differences were observed in glucose infusion rates (GIR) (0.72 ± 0.03 vs 0.58 ± 0.03 mmol/kg/min), active GLP-1 (1.7 ± 0.1 vs 1.2 ± 0.1 pmol/L), plasma insulin (1279.26 ± 228.49 vs 752.84 ± 231.96 pmol/L) and insulin secretion rates (ISR) (1598.4 ± 133.2 vs 1065.6 ± 133.2 pmol/min). Post-meal (190-340mins.)**:** At matched plasma glucose (9.34 ± 0.03 vs 9.26 ± 0.04 mmol/L), further significant ($p<0.001$ for all parameters) increments over pre-meal were seen in all parameters in both groups, and significant ($p<0.001$ for all between group comparisons) differences were observed in GIR (0.83 ± 0.02 vs 0.76 ± 0.02 mmol/kg/min), active GLP-1 (6.4 ± 0.6 vs 3.1 ± 0.7 pmol/L), plasma insulin (5809.49 ± 988.97 vs 3833.64 ± 993.13 pmol/L) and ISR (3230.1 ± 266.4 vs 2664.0 ± 266.4 pmol/min).
Conclusion: Our data demonstrate for the first time in HV that the GLP-1 stabilizing property of sitagliptin has significant GDIS effects in the preprandial state, with further significant augmentation in the prandial state. The HGC-MTT appears to be a novel reliable tool for measurement of preprandial and prandial GDIS in a single experiment in a single dose setting in HV.

Differences in insulin release between long term type 2 diabetes mellitus and NGT - a model of discovery of changes in proteins using liquid chromatography-mass spectrometry (LC-MS)

M. Pepaj, P.M. Thorsby;
Oslo University Hospital, Aker, Hormone Laboratory, Norway.

Background and aims: Proteomics-based candidate biomarker discovery efforts have gained significant attention due to the power of these technologies for analyzing complex protein mixtures and their potential for identifying novel markers indicative of disease. The aim of this project is to apply advanced quantitative proteomic methodology to quantify relative changes in protein levels in serum samples from individuals with normal glucose tolerance (NGT) and long term type 2 diabetes (T2DM) investigated with hyperglycaemic.
Materials and methods: 13 men 7 women were followed for 10 years, with these baseline characteristics: age 58,4 (6,1) (mean (SD)) years, diabetes duration 7,0 (3,0) years, HbA1c 8,5 (1,6)%, BMI 25,8 (2,7) kg/m2, weight 76,6 (10,3) kg and anti-GAD negative. Hyperglycaemic clamp was preformed in all with glucose increase of + 7.2 (1.10) mmol/l during two hours, followed by a bolus of 5 mg iv arginine stimulation. For comparison, the hyperglycaemic clamp with arginine was also performed in seven aged-matched healthy volunteers. Our approach uses an enzymatic 18O stable isotope labeling procedure followed by liquid chromatography- mass spectrometry (LC-MS) to directly detect and quantitatively compare proteins present in patients with T2DM to be compared with persons with NGT during the hyperglycaemic clamp. With this approach, we can rapidly identify and measure difference in expression levels for thousands of peptides in a single analysis. So far only insulin secretion data from the hyperglycemic clamp have been analyzed.
Results: Insulin secretion measured as the mean increase in C-peptide concentrations after one hour of hyperglycaemia were significantly lower in patients than in controls, 189 (99) pmol/l vs 1044 (433) pmol/l, $p < 0.001$. Also, the maximal C-peptide value after arginine stimulation was significantly lower in patients than in controls, 723 (583) pmol/l vs 4292 (2114) pmol/l, $p< 0.001$, This represents 38% increase in the mean C-peptide level during the first hour of hyperglycaemia in patients compared to a 97% increase in healthy volunteers, and 71% increase in patients after arginine compared to 115% in controls. Fig 1
Conclusion: There are large differences in insulin secretion between T2DM and NGT after more than seventeen years of diabetes, but rapid insulin release is still present when stimulating the b-cells with arginine. The difference in insulin response may be due to undiscovered proteins.

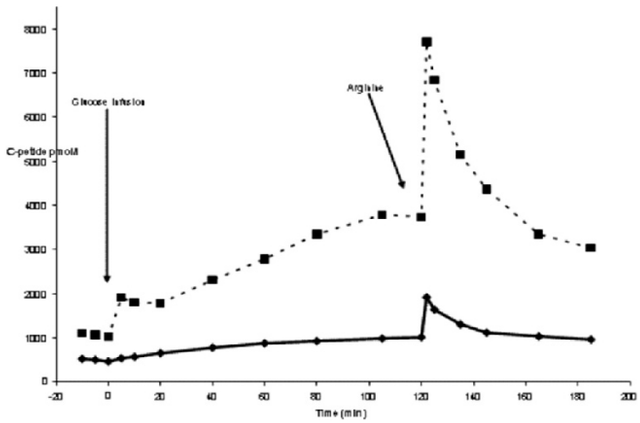

Fig 1 Mean levels of C-peptide during hyperglyceamic clamp with arginine (5g) infusion after two hours of 8 mmol/l hyperglyceamia (• and black line) and 7 healthy volunteers (dotted line)

The aging type 2 diabetes. Differential effects of aging and diabetes on insulin sensitivity, beta cell function and incretin production

B. Geloneze[1,2], A.C.J. Vasques[1], M.S. Oliveira[1], F.S. Novaes[1], J.C. Pareja[1,2], M.J.A. Saad[3,2], M.A. Tambascia[1,2];
[1]Laboratory of Investigation on Metabolism and Diabetes - LIMED, University of Campinas, [2]National Institute of Science and Technology on Obesity and Diabetes, Campinas, [3]Laboratory of Clinical Investigation on Insulin Resistance, University of Campinas, Brazil.

Background and aims: Diabetic physiopathology is a combination of insulin resistance, beta cell dysfunction, and impaired incretin action or production. Aging is related to increased prevalence of T2DM. The aim of the present study is to quantitate the separate impact of aging and diabetes on the diabetic physiopathology [i.e., insulin sensitivity (IS), beta cell function and incretin production].
Materials and methods: Hyperglycemic clamp (HC) and meal tolerance test (515 Kcal) were performed in 48 subjects divided in 24 with normal glucose tolerance [NGT], and 24 with type 2 diabetes (DM) with less than 5 years of disease and taking OADs. Both NGT and DM groups were composed by 12 middle-age (35 to 50 y) and 12 aging subjects (> 65 y), with a BMI below 30 kg/m2. IS and insulin production were evaluated by HC. During the 180 minutes MTT, both incretins: GLP-1 and GIP were evaluated.
Results: The IS (Clamp-derived insulin sensitivity index - ISI, and glucose infusion rate - GIR) were reduced in DM compared with NGT ($p < 0.01$). These results were also affected by aging, but in a less intense manner when subjects were stratified by aging category ($p < 0.05$). Beta cell function (Clamp-derived derived first and second phase insulin secretion in relation to ISI - First and Second phase Disposition Indexes - DI) were reduced in DM compared to NGT ($p<0.05$). Aging did not affect DI in NGT, but exacerbates the difference between DM groups ($p<0.01$). The 180min total GIP production were similar among groups. GIP incremental area under the curve AUC(0-60 min) were greater in DM groups ($p<0.05$), but not affected by aging. The 180min GLP-1 production were reduced in aging groups ($p<0.05$), but independent of the

presence of DM. In middle age group, total GLP-1 production was reduced in DM in comparison to NGT (p<0.05). GLP-1 incremental AUC(0-60 min) were reduced in aging groups independent of the presence of DM (p<0.05).
Conclusion: In non-obese subjects, diabetic state and aging impair insulin sensitivity and incretin production independently of one another. Insulin production is affected by the DM itself, and aging exacerbates this condition. Aging associated defects superimposed diabetic physiopathology, in special regarding incretin production. The knowledge of complex relationship of aging and glucose homeostasis in diabetic and non-diabetic subjects could support the development of physiopathological-based diabetic therapies.

Risk factors for the development of diabetes after acute beta cell mass reduction

G. Muscogiuri[1], G. Sorice[1], L. Marselli[2], A. Prioletta[1], T. Mezza[1], M. Tancredi[2], A. Lassandro[1], P. Marchetti[2], A. Giaccari[1];
[1]Department of Endocrinology, Rome, [2]Department of Endocrinology and Metabolism, Pisa, Italy.

Background and aims: Insulin secretion (IS) defects and insulin resistance (IR) contribute to the onset and progression of type 2 diabetes (T2D), though the relative contribution of each factor is still unknown. In our series we studied the role of β cell in the pathogenesis of type 2 diabetes by analyzing patients undergoing acute β-cells mass reduction after duodeno-pancreatectomy (DP).
Methods: Eight patients were evaluated for glucose tolerance (OGTT), IS (hyperglycemic clamp), β-cell mass (arginine bolus) and insulin sensitivity (hyperinsulinemic euglycemic clamp; 40 mU/m2) before and after DP. Abdominal-CT was performed to quantify visceral adipose tissue (VAT) and subcutaneous adipose tissue volumes (SAT). During surgery we collected pancreas specimens on which we performed positive insulin area measurements (PIA) by a computer assisted system.
Results: there were 4 women and 4 men aged (mean ± SD) 58.7 ± 21.9 years, BMI (mean ± SD) 29.6 ± 6.1 kg/m2. At the enrollment no patient reported history of type 2 diabetes. Before surgery 5 patients resulted IGT. After DP, 4/8 developed diabetes, 3/8 IGT and 1/8 preserved normal glucose tolerance. There were not significative changes in whole body glucose uptake (4.3±1.1 vs. 3.8±1.1 mg/kg/min before and after surgery respectively; p=NS) following DP. A significant reduction of β-cell mass calculated as AUC of insulin after arginine bolus (AUC Arg) was detected after surgery (before 7485.8 ± 363.5 vs. after surgery 2312.2 ± 239.5 μUI/ml/min; P=0.001) as well as the I and II phase of IS (AUC I: 186.5 ± 17.4 vs. 95.0 ± 10.9 μUI/ml/min, P=0.04; AUC II: 3124.1 ± 194.3 vs. 1409.7 ± 162.4 μUI/ml/min, P=0.001). PIA was 1.67±1.43%. When AUC I and II were adjusted for beta cell mass (AUC Arg), we found a significative increase in the AUCI/AUCArg after surgery (0.05±0.03 vs. 0.14±0.12; p=0.03) but no changes in AUCII/AUCArg. We found a significant relationship of Δ(AUCI/AUCArg) with IR(r=-0,84; P=0.03) and VAT (r=0.82; P=0.03) but no with SAT, indicating that insulin resistant subjects better partially recovered the first phase of IS after surgery. In the same way PIA correlated with the degree of IR (r=-0.76;p<0.05) and VAT (r=0.9; p<0.01) but not with SAT.
Conclusion: We highlighted the unequal impact of acute β-cell mass reduction on glucose control. All patients experienced reduction in IS after DP although only half of them developed diabetes. We hypothesize that the VAT and the consequent IR may induce hypertrophy/hyperplasia of β cell mass, as documented by the strong relationship of PIA with IR and VAT. Although the IR subjects had a better partial recovery of first phase of IS, they developed diabetes. Thus, they were not able to overcome IR, indicating that loss of β-cell mass rather than the first phase plays the major role in the pathogenesis of diabetes.

Long-term recovery of beta cell function after partial pancreatectomy in humans

B.A. Menge[1], T.G.K. Breuer[1], H. Schrader[1], W. Uhl[2], W.E. Schmidt[1], J.J. Meier[1];
[1]Department of Medicine I, [2]Department of Surgery, St. Josef-Hospital, Bochum, Germany.

Background and aims: Glucose homeostasis and insulin secretion are significantly altered after partial pancreatectomy in humans. The present study was designed to evaluate the long-term consequences of a hemipancreatectomy in 20 patients (12 males, 8 females; age 57.4 ± 13.0 years) with chronic pancreatitis (CP; n = 10) or benign pancreatic and extra-pancreatic tumours (n = 10).
Materials and methods: In all patients, a 240 min oral glucose challenge was performed before and shortly (30.0 ± 33.9 days) after surgery, as well as after a follow-up of 3.1± 0.5 years. Plasma concentrations of glucose, insulin and C-peptide were determined, and indices of insulin sensitivity and insulin secretion were determined.
Results: In CP patients, glucose concentrations immediately after surgery were higher at t = 180-240 min compared to pre-operative levels ($p < 0.05$). At the time of follow-up, the post-challenge glucose concentrations were intermediate in between the pre-operative assessment and the experiments immediately after surgery ($p < 0.05$). Insulin secretion was reduced by ~50% immediately after surgery in CP patients ($p < 0.001$). The patterns of insulin and C-peptide concentrations determined at the time of follow-up were significantly shifted back towards pre-operative levels ($p < 0.001$), although complete normalization was still not achieved at this point in time. In the adenoma/tumour patients, fasting and post-challenge (from t = 150 - 240 min) glucose concentrations were higher immediately after surgery, but were almost completely normalized at the time of follow-up ($p < 0.001$). Likewise, post-challenge insulin and C-peptide concentrations had increased significantly compared to the early post-operative levels ($p < 0.0001$). The Matsuda index of insulin sensitivity was unchanged during the follow-up in both groups. However, the oral disposition index was restored to pre-operative levels at the time of follow-up both in CP patients (0.45 ± 0.1, 0.29 ± 0.07, and 0.60 ± 0.1 mM^{-1} , before surgery, shortly after surgery and at the follow-up, respectively; $p = 0.02$) and in the tumour/adenoma patients (1.2 ± 0.3, 0.8 ± 0.2, 1.4 ± 0.3 mM^{-1}, respectively; $p = 0.03$).
Conclusion: These findings demonstrate a capacity for recovery of glucose control after partial pancreatectomy and suggest that beta-cell function can improve significantly over time even in adult humans. Whether this is due to increases in beta-cell mass or function cannot be clarified from this study, but given the limited capacity for beta-cell regeneration in adult humans, functional improvements in insulin secretion are most likely.

Ghrelin suppresses insulin secretion and compromises beta cell function in healthy humans

J. Tong[1], R.L. Prigeon[2], H.W. Davis[1], M.H. Tschöp[1], D. D'Alessio[1];
[1]Internal Medicine, University of Cincinnati, [2]School of Medicine, University of Maryland, Baltimore, USA.

Background and aims: The orexigenic gut hormone ghrelin and its receptor, the growth hormone secretagogue receptor 1a, are present in pancreatic islets. While ghrelin reduces insulin secretion in rodents, its effect on insulin secretion in humans has not been established. Our objective was to test the hypothesis that circulating ghrelin suppresses glucose-stimulated insulin secretion in healthy subjects.
Materials and methods: Acyl ghrelin (0.2 and 0.6 pmol/kg/h) or saline was infused in 10 healthy subjects (4M/6F; age 29.5 ± 5.2 y; BMI 22.8 ± 3.0 kg/m^2, fasting plasma glucose 5.2 ± 0.1 pM, mean ± SEM) on 3 separate occasions in a counterbalanced fashion. The ghrelin was infused for 45 minutes to achieve steady-state levels and continued through a 180-minute frequently sampled intravenous (IV) glucose tolerance test (FSIGT). The acute (first phase) insulin response to IV glucose (AIRg) was calculated from plasma insulin concentrations between 2 and 10 min after the glucose bolus. Insulin sensitivity index (S_I) and glucose effectiveness at basal insulin (S_g) were quantified using the minimal model of glucose kinetics. Disposition index (DI), a measure of β-cell function, was a product of AIRg and S_I. IV glucose tolerance was measured by the glucose disappearance constant (Kg) from 10 to 20 min.
Results: Ghrelin infusion did not alter fasting plasma insulin or glucose, but the 0.6 pmol/kg/h dose decreased AIRg (569.6 ± 187.0 vs. 861.2 ± 288.5 min. mU/l^{-1}) and S_g (0.015 ± 0.002 vs. 0.023 ± 0.002 min^{-1}) significantly compared to the saline control ($p < 0.05$ for ghrelin vs. control). Furthermore, both the 0.2 and 0.6 pmol/kg/h ghrelin infusions decreased DI significantly (1940 ± 570, 1669 ± 628 vs. 3825 ± 1283, respectively, $p < 0.05$ for both doses vs. control). Ghrelin administration did not alter IV glucose tolerance as measured by Kg.
Conclusion: Exogenous ghrelin reduces the first-phase insulin response to IV glucose and lowers β-cell function in healthy humans. These findings raise the possibility that endogenous ghrelin has a role in control of regulation

of insulin secretion, and that ghrelin antagonists could improve β-cell function.

NEFA kinetics during an OGTT after islet transplantation
G. Ward, Islet Tx Study Group;
Endocrinology & Diabetes, St. Vincent's Health Melbourne, Australia.

Background and aims: In addition to its effects on carbohydrate metabolism, insulin inhibits lipolysis and promotes lipogenesis/fat storage. Abnormal NEFA kinetics are a feature of both type 1 & 2 diabetes but have not been studied in type 1 diabetes patients after intra-portal allogeneic islet transplantation. The liver is an important site of NEFA synthesis and islet recipients are known to develop periportal steatosis secondary to paracrine effects of high local concentrations of insulin. In view of the transplanted islets' heterotopic location in close proximity to hepatocytes, we aimed to evaluate NEFA dynamics in response to an oral glucose challenge in islet recipients who achieved insulin-independence.
Materials and methods: A 4-hour 75g OGTT was performed in 2 insulin-independent islet recipients, 3 patients with type 2 diabetes (T2DM) on oral medications (withheld 1 week pre-study) and 5 controls. Plasma glucose, insulin and NEFA were assayed at 0,30,60,90,120,150,180 and 240min.
Results: Mean age of islet recipients, T2DM patients and controls was 56 ± 4, 55 ± 1 and 49 ± 5 SEM years respectively; mean BMI was 19.8 ± 1.0, 37.5 ± 4.2 and 25.1 ± 1.4 SEM kg/m^2; mean HbA1c was 5.7 ± 0.3, 7.0 ± 0.3 and 5.5 ± 0.1 SEM %. Although recipients had diabetic profiles (mean glucose: fasting 6.3 ± 0.2, after 2 hours 13.0 ± 1.4 SEM mmol/l), they were insulin - independent maintaining HbA1c ≤ 6% without oral hypoglycaemics. Insulin secretion(AUCins corrected for glucose) during OGTT was lower in recipients and T2DM subjects when compared with controls(14.7%, 14.1%, 100% respectively). When corrected for prevailing insulin sensitivity, as measured by Kahn's modification of Disposition Index for OGTT[Δins(0-30min)/Δglu(0-30min)/fasting insulin], insulin secretion was 30.1% and 19.7% normal in recipients and T2DM subjects. The following table summarizes indices of NEFA kinetics in all 3 groups:

	Islet recipients (n=2)	Type 2 Diabetes (n=3)	Controls (n=5)
NEFA nadir (mmol/l)	0.014 ± 0.007	0.063 ± 0.025	0.035 ± 0.006
2 hr NEFA (mmol/l)	0.019 ± 0.010	0.130 ± 0.036	0.056 ± 0.010
Time to nadir	140 ± 20min	157 ± 19min	156 ± 6min
Time to plateau	90 ± 17min	137 ± 38min	66 ± 6min
NEFA suppression(area below basal)(0-120min) (mmol/l.min)	42 ± 11	29 ± 4	38 ± 6
% NEFA suppression to nadir †	97 ± 1	90 ± 4	93 ± 1
% NEFA suppression to 120min††	96 ± 2	80 ± 5	89 ± 2

††(fasting NEFA - 2hr NEFA)/fasting NEFA x 100%
*slope of the regression line relating the log of NEFA levels from time 30-90min
**kNEFA(30-90min)/incremental AUC_{ins} from 30-90min

Conclusion: This is the first report of NEFA suppression in intra-portal islet recipients during an OGTT. We found NEFA dynamics in islet recipients are not impaired and may be even better than in controls despite reduced peripheral insulin secretion and immunosuppressants known to cause dyslipidemia. We also found that despite marginally better glycaemia and peripheral insulin secretion when compared with T2DM subjects, recipients had disproportionately greater NEFA suppression. As the liver plays a central role in lipid metabolism/transport, high *periportal* insulin levels (secondary to proximity of transplanted β-cells to hepatocytes) in recipients could explain the normal and even improved NEFA dynamics. An alternative explanation would be that very little insulin is required for normal NEFA suppression. These preliminary findings echo those of Rickels et al, who found improved NEFA disposal in islet recipients compared with controls, during insulin-modified IVGTT. This data is of interest as improved NEFA dynamics post-transplant could contribute to enhanced glucose disposal by reducing glucolipotoxicity. Further studies, however, with larger numbers of subjects are required.

Effect of ameliorating glucotoxicity on incretin secretion in patients with type 2 diabetes
S.-H. Ko[1], S.-H. Lee[1], K.-H. Yoon[2], Y.-B. Ahn[1];
[1]Internal Medicine, St. Vincent's Hospital, Suwon, [2]Internal Medicine, Seoul St. Mary's Hospital, Republic of Korea.

Background and aims: The condition of type 2 diabetes and accompanying hyperglycemia and insulin resistance leads to the impairment in secretion or action of the incretin hormones. In this study, we aimed to determine whether reversal of hyperglycemia and insulin resistance can affect incretin secretion in patients with type 2 diabetes. The associated factors with incretin secretion were also investigated.
Materials and methods: Meal tolerance test (MTT) was performed in eighteen poorly-controlled diabetic (pDM) patients and fifteen well-controlled diabetic (wDM) patients. Fourteen patients in pDM group underwent follow-up MTT after mean 2.4 months of insulin treatment. Plasma concentrations of glucose, insulin, C-peptide, glucagon, intact glucagon-like peptide 1 (iGLP-1) and total glucose-dependent insulinotropic polypeptide (tGIP) were measured and their secretions during MTT were calculated by total and incremental area under the curve (TAUC and IAUC) values.
Results: Post-treatment HbA1c level was significantly improved in pDM group (from 11.2 ± 0.9 to 7.9 ± 0.9%). The relative secretion of incretin hormones adjusted by glucose levels were mildly but significantly increased in pDM group after treatment (TAUCiGLP-1/TAUCglucose, from 0.07 ± 0.01 to 0.08 ± 0.01; TAUCtGIP/TAUCglucose, from 0.19 ± 0.03 to 0.24 ± 0.03; IAUCtGIP/IAUCglucose, from 0.73 ± 0.14 to 0.91 ± 0.13), although they were still significantly lower when compared to wDM group. IAUCiGLP-1 was negatively correlated with insulin resistance ($r = -0.446$, $P = 0.011$) while IAUCtGIP was positively correlated with β-cell function ($r = 0.418$, $P = 0.016$) assessed by homeostasis model assessment.
Conclusion: Intensive insulin treatment increased the relative secretory capacity of incretin hormones adjusted by glucose levels. GLP-1 secretion showed negative correlation with the index of insulin resistance. These findings indicate the importance of ameliorating glucotoxicity and lowering the degree of insulin resistance to improve incretin secretion in patients with type 2 diabetes.

Acute exposure to palmitate induces endoplasmic reticulum stress and impairs insulin action in isolated human skeletal muscle strips

P.A. Skrobuk[1,2], J. Kärkkäinen[1,2], H.A. Koistinen[1,2];
[1]Minerva Institute, Helsinki, [2]Division of Cardiology, Department of Medicine, Helsinki University Central Hospital, Finland.

Background and aims: Obesity and high fat diet have been linked to insulin resistance, which may involve endoplasmic reticulum (ER) stress. Here, we studied the effect of acute palmitate exposure on insulin action on glucose transport (GT), glycogen synthesis, insulin signaling and ER stress.
Materials and methods: We studied 18 men (47±3 years, BMI 26.2±0.8 kg/m2, fP-gluk 5.5±0.1 mM). Open muscle biopsy was obtained from m. vastus lateralis, and small muscle strips were incubated for 4 h with or without (w/o) palmitate (1mM), and with or w/o insulin (1.2 nM).
Results: Insulin increased GT (in nmol/mg/20 min) 1.9-fold (from 0.6±0.05 to 1.2 ±0.1, p<0.001). With palmitate, basal GT tended to be increased (0.9±0.1, p=0.062), insulin-stimulated GT was unchanged (1.2±0.1), and insulin action on GT (insulin-stimulated minus basal) reduced by 49 % (p=0.068). Palmitate reduced insulin-stimulated glycogen synthesis 18 % (70±13, vs 85±15 nmol/g/h, p<0.02), but did not affect AKT-Ser473 phosphorylation. When men were divided by BMI, insulin increased GT with palmitate in lean, but not in overweight men. Palmitate induced ER stress (1.3-fold increased phosphorylation of eIF2α) in overweight but not in lean men
Conclusion: Acute exposure to palmitate impairs insulin action in human muscle strips. This effect is more pronounced in men with overweight, and may involve activation of ER stress.

ER Stress in adipocytes inhibits insulin signalling, represses lipolysis and alters the secretion of adipokines without inhibiting glucose transport

L. Xu, G.A. Spinas, M. Niessen;
Endocrinology, Diabetology & Clinical Nutrition, University Hospital of Zurich, Switzerland.

Background and aims: ER stress and activation of the unfolded protein response (UPR) contribute to insulin resistance and the development of diabetes in obesity. It was shown previously in hepatocytes that the UPR activates c-jun N-terminal kinase (JNK) which phosphorylates insulin receptor substrate (IRS) proteins on serine residues thereby inhibiting insulin signal transduction. Here we describe how ER stress affects insulin signalling and the biological function of adipocytes.
Materials and methods: ER stress was induced with either thapsigargin or tunicamycin. Activation of insulin signal transduction and of the unfolded protein response (UPR) were assessed by Western blotting. The function of 3T3-L1 adipocytes and of primary mouse adipocytes was assessed by measuring insulin-dependent 14C-2-deoxy-D-glucose uptake, glycerol to analyse lipolysis and by multiplex analysis of culture supernatants for various cytokines.
Results: In addition to inhibition of IRS we found that ER stress downregulates the expression of the insulin receptor. Concomitantly, insulin-induced activation of Akt/PKB and of ERK1/2 was strongly inhibited. Ectopic expression of IRS1 or IRS2 strongly counteracted the inhibitory effect of ER stress on insulin signalling while pharmacological inhibition of JNK with SP600125 resulted only in a mild improvement. ER stress decreased the secretion of the adipokines adiponectin and leptin, but strongly increased secretion of IL-6. ER stress inhibited expression and insulin-induced phosphorylation of AS160, reduced lipolysis but did not inhibit glucose transport. Supernatants collected from 3T3-L1 adipocytes undergoing ER stress improved or impaired proliferation when used to condition the culture medium of INS-1E β-cells dependent on the degree of ER stress.
Conclusion: ER stress in adipocytes might initially lead to changes resembling early pre-diabetic stages which at least in part support the regulation of systemic energy homeostasis.

Endoplasmic reticulum stress plays a role in both the adaptive and deleterious effects of lipid on insulin signalling in liver cells

C.S. Achard, D.R. Laybutt;
Diabetes and Obesity Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Background and aims: Insulin resistance (IR) in peripheral tissues including liver, combined with β-cell failure, leads to type 2 diabetes. Obesity and associated lipid oversupply is a likely cause of IR in liver but the mechanisms responsible remain unknown. The endoplasmic reticulum (ER) stress response has emerged as a potential signalling pathway involved in obesity-associated IR. Furthermore, high levels of fatty acids, particularly saturated forms such as palmitate, can induce ER stress in liver cells, but its necessary contribution to IR has not been elucidated. We therefore investigated whether ER stress was necessary for palmitate-induced hepatic IR. Moreover, as the ER stress response has also been described as a protective signalling pathway required for cell adaptation, we investigated the consequences of chronic mild ER stress on hepatic insulin signalling.
Materials and methods: To examine the role of ER stress in lipid-induced IR, human hepatoma HepG2 cells or mouse primary hepatocytes were exposed for 1-24 h to BSA-coupled palmitate (100-750 μmol/l) in presence or not of chemical chaperones trimethylamine N-oxide (TMAO) or tauroursodeoxycholic acid (TUDCA). To investigate the effects of prolonged mild ER stress activation on insulin signalling, HepG2 cells were exposed to low level of thapsigargin (2-2.5 nmol/l) or tunicamycin (0.1 μg/ml) for 3-6 days (two passages), or to palmitate (100-200 μmol/l) for 6-12 days (three passages). Activation of the ER stress response and insulin signalling pathway were examined using Western blot analysis and glycogen synthesis assay.
Results: In HepG2 cells, exposure to palmitate dose- (250-750 μmol/l) and time- (1-24 h) dependently led to activation of two arms of the ER stress response as evidenced by increased EIF2α phosphorylation, XBP1 splicing and JNK activation. We confirmed in hepatocytes that elevated levels of palmitate (500-750 μmol/l) induced an increase in PERK phosphorylation, XBP1 splicing and CHOP expression. In HepG2 cells and primary hepatocytes, this is associated with defective insulin signalling (decreased insulin-stimulated Akt phosphorylation) and reduced insulin action (insulin-stimulated glycogen synthesis). Treatment of HepG2 cells or primary hepatocytes with TMAO (100 mmol/l) or TUDCA (500 μg/ml), respectively, attenuated palmitate-induced ER stress and partially reversed the defect in insulin signalling, demonstrating that ER stress makes a necessary contribution to lipid-induced IR in liver cells. However, strikingly distinct effects were observed following exposure to mild ER stress. Chronic exposure of HepG2 cells to low level thapsigargin, tunicamycin or palmitate led to enhanced insulin signalling (increased insulin-stimulated Akt phosphorylation), suggesting the establishment of an ER stress adaptive pathway. This was associated with an attenuated ER stress activation in response to subsequent high-level palmitate or thapsigargin (10 nmol/l) exposure.
Conclusion: Our results suggest chronic exposure of liver cells to low-level palmitate induces mild ER stress and an adaptive response that enhances insulin signalling and confers protection against acute palmitate-induced ER stress. However, more severe ER stress induced by chronically elevated palmitate overwhelms the adaptive response leading to IR. Thus, ER stress could contribute to both the adaptive and deleterious effects of lipid on insulin signalling in liver cells.

Endoplasmic reticulum stress induced by hyperglycaemia and saturated fatty acids is alleviated by salicylates in cultured primary human adipocytes

M. Langowska, S. Alhusaini, K.C. McGee, A.L. Harte, P.G. McTernan, S. Kumar, G. Tripathi;
CSRI, University of Warwick, Coventry, United Kingdom.

Background and aims: Obesity and type 2 diabetes mellitus (T2DM) are closely associated with chronic inflammation. Adipose tissue may have a significant role in obesity associated inflammation but, the mechanisms underlying the pathogenesis of obesity induced inflammation remains unclear. Recent findings indicate that endoplasmic reticulum (ER) stress is critical to the initiation and integration of pathways of inflammation and insulin action. The ER stress occurs when there is an accumulation of unfolded/misfolded proteins, in addition to other factors. This results in activation of the

unfolded protein response (UPR) to restore functional integrity which, leads to upregulation of master regulators of ER, PKR-like ER-regulated kinase (PERK), inositol requiring enzyme1α (IRE1α) and activating transcription factor6 (ATF6) and protein chaperones. Factors acknowledged to elicit cellular stresses are hyperglycaemia, hyperlipidaemia, viral infections and increased protein synthesis; the majority of which are features of obesity and T2D. Therefore, our aims were to determine the existence and causes of ER stress in human adipocytes.
Methods: Human abdominal subcutaneous (AbSc) adipose tissue (AT) was obtained from a Caucasian non-diabetic population (BMI: 27.9±7.3 kg/m^2: age 36-49 yrs; n=40; all female subjects) that underwent elective liposuction surgery, as part of the well established AT collection program. The human preadipocytes were isolated from stromal fraction, grown and fully differentiated into human adipocytes (n=5). Well differentiated adipocytes were then treated with tunicamycin (750ng/ml), high glucose (HG) (25 mM) and saturated fatty acids (SFA) (2 mM) and in combination with 20mM salicylate, salicylate alone and controls. To characterise protein expression of the key markers relevant to ER stress, inflammation and insulin signalling pathway, total protein and RNA was extracted from adipose tissue and cultured adipocytes using standard protocol. Western blots and Real-Time RT-PCR were performed to examine protein and RNA expression levels.
Results: The expression of ER stress proteins Calnexin1, glucose regulated protein (Grp78)/BiP1, Ero-1α, protein disulfide isomerise (PDI), IRE1α and Phospho-PERK were significantly increased in AbSc AT from obese compared to lean subjects (n=4; p<0.05 to p<0.001). PERK activated phospho-eIF2α (n=5; p<0.005) was significantly induced by tunicamycin, HG and SFA (p<0.001) proving the existence of ER stress in differentiated human adipocytes. ATF6 mRNA expression was also significantly induced by tunicamycin and HG but not SFA. Grp78/Bip was also significantly induced by tunicamycin and SFA. Down-stream targets Calnexin, PDI, Ero1-Lα and Chop were also significantly induced by all three treatments (p<0.05 to p<0.001). In the same adipocytes ER stress was significantly reduced when treated with anti-inflammatory compound salicylate. Similarly, phospho-Akt (S473) (n=5; p<0.002), was also activated when ER stress was down-regulated by salicylate.
Conclusion: Our results demonstrate that hyperglycaemia (HG) and SFA induce ER stress in human adipocytes and therefore could cause increased inflammation and insulin resistance in human adipose tissue. We also demonstrate that salicylate alleviates this stress and also activates Akt which could lead to increased insulin sensitivity.

Doubling of both insulin sensitivity and beta cell function explains remission of type 2 diabetes within one week after Roux-en-Y Gastric Bypass

N.B. Jorgensen[1], S.H. Jacobsen[1], D. Worm[1], D.L. Hansen[1], L. Naver[2], L.E. Hvorlis[2], J.J. Holst[3], S. Madsbad[1];
[1]Dep. of Endocrinology, Hvidovre Hospital, [2]Dep.of Surgery, Hvidovre Hospital, [3]Dep. of Biomedical Sciences, University of Copenhagen, Denmark.

Background and aims: Roux-en-Y gastric bypass (RYGB) for morbid obesity is known to cause remission of type 2 diabetes within days after surgery, but the mechanistic explanations of this phenomenon are poorly understood. Here we report the acute effects of RYGB on glucose metabolism within 4-6 days after the operation.
Materials and methods: 8 patients referred with the diagnosis of type 2 diabetes (treated with oral antiglycaemic agents or diet) and a fasting P-glucose of more than 7 mM on the last weekday before the operation, were included in the study. Patients had a BMI of 45 ± 1,8 kg/m^2, an HbA1c of 6.9 ± 0.3 and an average age of 53 ± 3 y. A mixed meal tolerance test was performed 1-3 days before and 4-6 days after bypass surgery. 3 fasting blood samples were drawn, before patients were given a 200 mL liquid meal (Fresubin Energy, 1260 kJ, protein E% 15, carbohydrate E% 50, fat E% 35), that was ingested over a 30 min period. Blood was sampled frequently over a 4 h-period after meal start for measurement of plasma glucose, insulin and c-peptide. To relate beta-cell function to the ambient insulin resistance, disposition index was calculated as the insulinogenic index (0-30 min C-peptide/0-30 min glucose) (IGI) multiplied by 1/HOMA-IR.
Results: A significant reduction in the fasting plasma glucose levels was observed after RYGB compared to preoperative levels (9.2 ± 0.98 mmol/l vs. 7.2 ± 0.43 mmol/l, p<0.05), and an even greater reduction in mean 2 h postprandial glucose levels (12.3 ± 1.2 mmol/l vs 9.2 ± 0.68 mmol/l, p<0.01) could be demonstrated. Fasting insulin levels were also reduced postoperatively (17.4 ± 3.27 μU/ml vs. 10.9 ± 2,09 μU/ml, p<0.01), as was the corresponding C-peptide levels (1.68 ± 0.21 nmol/l vs. 1.36 ± 0.24 nmol/l, p < 0.01). Accordingly, insulin resistance evaluated by HOMA-IR was reduced by almost 50% postoperatively (6.71 ± 1.12 mmol/l*μU/mL vs. 3.55 ± 0.71 mmol/l*μU/mL, p<0.01). In parallel the Matsuda Index increased from 2.6 ± 0.5 before to 4.3 ± 0.8 after surgery (p<0.05). The incremental area under the curve for C-peptide (210 ± 27 vs. 272 ± 40 min*nmol/l, p=0,055) showed a clear trend towards being greater after surgery, but failed to reach statistical significance. The insulinogenic index (IGI) was not influenced by RYGB (0.57 ± 0.10 before and 0.54 ± 0.14 after), however, the disposition index was significantly increased after compared to before surgery (0.097 ± 0.02 before vs. 0.163 ± 0.03 after, p<0,03).
Conclusion: Within one week after RYGB fasting P-glucose and 2 h postprandial glucose levels in type 2 diabetics are significantly reduced compared to pre surgical levels. These changes are associated with a near doubling of both insulin sensitivity and beta-cell function.

669

Evaluation of insulin secretion and insulin sensitivity in diabetic and non-diabetic patients with morbid obesity before and after metabolic surgery

G. Schernthaner[1], J.M. Brix[1], H.-P. Kopp[1], G. Pacini[2];
[1]1 Med Department, Rudolfstiftung Hospital, Vienna, Austria, [2]Metabolic Unit, ISIB-CNR, Padua, Italy.

Background and aims: In recent years metabolic surgery (MS) is widely used in patients with morbid obesity (MO) and a resolution of diabetes mellitus (DM) was seen in most patients presenting with DM before MS. The mechanisms for the "cure" of DM are still widely unknown but seem to be rather complex. Information about the change of insulin secretion and insulin sensitivity before and after MS is very limited in particular when MO obese patients with and without DM are compared.
Materials and methods: We investigated the insulin secretion and insulin sensitivity in 88 patients with MO (BMI 46.3±0.7 kg/m^2; 40.7± 1.2 years) before and 2 years after MS. Before the intervention, 16 patients had DM and 72 were nondiabetic (Non-DM). An oral glucose tolerance test (OGTT; 75 g glu-

cose) was performed before and after MS, as well as in 30 nondiabetic control (CO) subjects (mean BMI 28.4±1.4kg/m²) with similar age and sex. Insulin sensitivity was evaluated at fasting with QUICKI and during the OGTT with dynamic OGIS; ß-cell function was assessed with the insulinogenic index (IGI) as the ratio of the area under the insulin to that of glucose, representing the ability of the beta cell to respond to the glucose stimulation.
Results: The characteristics of the subjects and metabolic parameters are shown in Table 1. In the pre-operative (pre-op) state MO patients, compared to CO, showed low insulin sensitivity, both QUICKI and OGIS, and high insulin secretion (IGI). DM and non-DM only differ for the glucose pattern (p<0.003), but no difference was found for OGIS (307±55 vs. 303±19) and IGI (75±6 vs. 88±19). After surgery, OGIS and QUICKI increased till normalization (440±15 and 0.44±0.01, respectively), being similar to those of CO in all subjects (p>0.35). IGI (68±7), though markedly reduced was still higher than in CO (p=0.006). Out of the 16 MO who were diabetic pre-surgery, only 4 remained diabetic after surgery. No specific parameter, assessed pre-surgery, seems to predict the post-surgery status of the DM.
Conclusion: In conclusion, metabolic surgery, and the consequent loss of weight, is able to restore normal insulin sensitivity, even in those diabetic subjects who remain diabetic, implying that obesity per-se is more important than diabetes in modulating the metabolic parameters; i.e., when BMI is elevated, possible additional effects of diabetes are masked by those of obesity. Beta cell function remains elevated, indicating that the pancreas seems to remain up-regulated, despite the reduction of BMI and the increase in insulin sensitivity.

Table1-Patients characteristics

	all patients before MS	CO	p-value
HbA1c (%)	5.9±0.1	5.3±0.1	<0.001
BMI (kg/m²)	46.3±0.7	28.4±1.3	<0.001
QUICKI	0.36±0.00	0.46±0.01	<0.001
OGIS (ml/min¹/m²)	318.2±7.6	459.2±16.2	<0.001
Insulinogenic Index	95.1±7.1	36.8±4.1	<0.001
AUC-Glucose (mol/L 2h)	0.86±0.02	0.67±0.03	<0.001

670

Improvement of first-phase insulin secretion and insulin sensitivity 72 hours after sleeve gastrectomy
D. Capoccia, C. Maglio, M. De Luca, F. Coccia, G. Borgonuovo, R. Asprino, C. Tiberti, F. Abbatini, M. Rizzello, N. Basso, F. Leonetti;
University of Rome Sapienza, Italy.

Background and aims: Obesity is a consequence of over-eating and sedentary life style. Type 2 Diabetes (T2D) is often associated and strongly related to obesity. Morbid obesity treatment actually provides medical therapy, lifestyle changes and bariatric surgery. Bariatric surgery is now considered the most successfully therapy for obesity. The purpose of this study was to evaluate the possible role of Laparoscopic Sleeve Gastrectomy (LSG) "per se" in the reversibility of type 2 diabetes immediately after surgery.
Materials and methods: We have studied insulin secretion and sensitivity in eighteen type 2 diabetic obese patients divided, by the statistical median of diabetes duration (10,5 years), in two groups: group A, patients with less than 10,5 years of disease; group B, patients with more than 10,5 years of disease. Ten non diabetic obese patients, group C, were included as control group. In all patients an Intra Venous Glucose Tolerance Test (IVGTT) was performed before and after LSG, as the following protocol: preoperatively, all patients underwent IVGTT after three days of fasting with only non caloric liquids and without antidiabetic drugs. Then, they normally fed for other three days before LSG and were submitted again to IVGTT three days after surgery without receiving neither nutrients or caloric liquids nor antidiabetic drugs, in order to avoid weight changes and interference of intestinal mechanisms on insulin secretion and sensitivity. Patients with fasting plasma glucose over 200 mg/dl before starting IVGTT were excluded.
Results: In group A, the first phase of insulin secretion promptly improved after bariatric surgery. In fact, the early insulin Area Under the Curve (AUC) significantly increased from 133.50 ± 86.70 μUI ml^{-1} · min to 254.10 ± 158.44 μUI ml^{-1} · min; p 0.012, indicating an increased glucose induced insulin secretion. The second phase of insulin secretion, expressed by the late insulin AUC, significantly decreased after SG in all groups: group A from 5275.00 ± 4533.900 μUI · ml^{-1} · min to 3552.41 ± 3326.32 μUI · ml^{-1} · min, p 0.04; group B from 3891.66 ± 2115.98 μUI · ml^{-1} · min to 1825.33 ± 988.83 μUI · ml^{-1} · min, p 0.045; group C from 15906.20 ± 3297.91 μUI · ml^{-1} · min to 3156.40 ± 2532.68 μUI · ml^{-1} · min, p 0.028. These findings suggest an improvement of insulin peripheral sensitivity.
Conclusion: Restoration of the first phase of insulin secretion, improved insulin sensitivity in type 2 diabetic obese patients, immediately after LSG, before any food passage through the gastrointestinal tract and before any weight loss, might be related to changes due to the removal of gastric fundus.

671

Early and long-term effects of Roux-en-Y gastric bypass on tissue insulin-resistance in type 2 diabetic and non-diabetic morbidly obese subjects
S. Camastra[1], A. Gastaldelli[2], E. Muscelli[1], S. Bonuccelli[1], B.D. Astiarraga[1], G. Scartabelli[3], S. Frascerra[1], E. Buzzigoli[2], S. Baldi[1], D. Ciociaro[2], F. Santini[3], M. Anselmino[4], E. Ferrannini[1];
[1]Department of Internal Medicine, University of Pisa, [2]Institute of Clinical Physiology, CNR, Pisa, [3]Department of Endocrinology, University of Pisa, [4]Bariatric Division, IV Surgery, S.Chiara Hospital, Pisa, Italy.

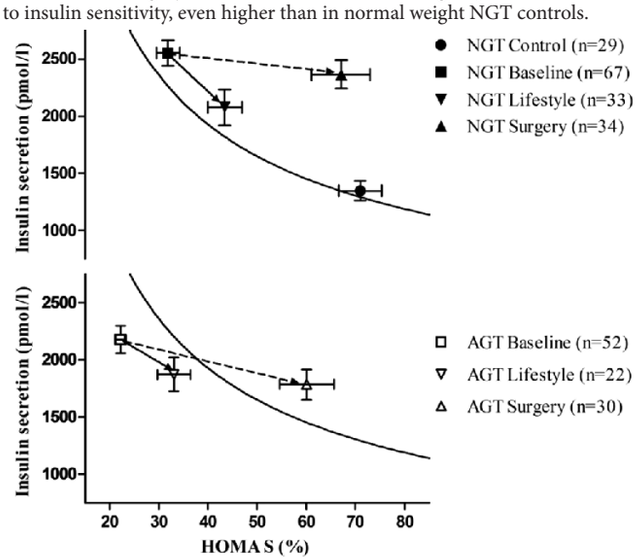
Background and aims: Weight loss after bariatric surgery is associated with a marked improvement of insulin resistance (IR), but the tissues involved in this effect have not been determined. Roux-en-Y gastric bypass (RYGB, a predominantly restrictive procedure) has been shown to improve IR in proportion to the weight loss in the long term; whether RYGB also has acute, weight-independent effects is controversial. Aim of our study was to measure the early and long-term effect of RYGB on IR at the level of muscle, liver and adipose tissue in morbidly obese non-diabetic and diabetic subjects.
Materials and methods: In 11 diabetic (T2D) (BMI=49±2 $kg·m^{-2}$) and 8 non-diabetic patients (OB) (BMI=55±2 $kg·m^{-2}$) matched by sex and age, we performed a euglycaemic hyperinsulinaemic clamp combined with tracers infusion (6,6-$^2H_2$-glucose and 1-^{2}H-glycerol to measure hepatic glucose production (HGP) and lipolysis (Ra-Gly), respectively) at baseline, 2 weeks and 1 year following RYGB. Muscle insulin sensitivity (M-IR = M value/steady state plasma insulin), hepatic insulin sensitivity (H-IR = HGP *x*fasting insulin) and adipose tissue insulin sensitivity (AT-IR = Ra-Gly *x* fasting insulin) were measured.
Results: Two weeks after RYGB, body weight was reduced minimally (7±1% in T2D and 4±1% in OB, p=0.01 for both); at 1 year, weight was reduced by 35±1% in T2D and 34±4% in OB (p<0.0001). Baseline fasting plasma glucose was reduced at two weeks and 1 year in both groups (7.9±0.6 *vs* 6.8±0.4 *vs* 5.2±0.2 mmol/l in T2D and 5.5±0.1 *vs* 5.3±0.1 *vs* 4.8±0.1 in OB, p<0.0001) as was fasting insulin (165±96 *vs* 92±11 *vs* 50±9 pmol/l in T2D and 125±22 *vs* 103±19 *vs* 40±5 in OB, p=0.0001). At 2 weeks, M-IS was marginally improved only in T2D (31±6 *vs* 43±6 $\mu mol \cdot min^{-1} \cdot kg_{FFM}^{-1} \cdot pM^{-1}$, p=0.05; in OB, 38±10 *vs* 36±5, p=ns), while at 1 year M-IS was doubled in OB and tripled in T2D (79±6 and 86±10 $\mu mol \cdot min^{-1} \cdot kg_{FFM}^{-1} \cdot pM^{-1}$, respectively, p<0.0001). At both 2 weeks and 1 year, H-IR was significantly reduced (2.0±0.3 *vs* 1.1±0.1 *vs* 0.7±0.1 $mmol \cdot min^{-1} \cdot kg_{FFM}^{-1} \cdot pM$ in T2D and 1.6±0.3 *vs* 1.2±0.3 *vs* 0.5±0.1 in OB, p=0.0001). At 2 weeks, AT-IR was modestly decreased only in T2D (71±12 *vs* 35±5 $\mu mol \cdot min^{-1} \cdot pM^{-1}$, p=0.003; in OB 47±11 *vs* 39±6, p=ns), while at 1 year the improvement was statistically significant in both groups (11±13 and 11±2 $\mu mol \cdot min^{-1} \cdot pM^{-1}$, respectively in OB and T2D, p<0.0001). One year after surgery, both H-IR and AT-IR were fully normalised as compared to a normal-weight control group (p=ns).
Conclusion: One year after RYGB and in concomitance with major weight loss, IR is improved in the principal target tissues (muscle, liver, adipose tissue) both in type 2 diabetic and non-diabetic subjects. In T2D patients, some improvement of tissue IR is evident acutely after surgery, in particular for liver and adipose tissue, and is likely responsible for the early amelioration of glycaemic control.

672

One year effect of gastric bypass and intensive lifestyle on insulin secretion in morbidly obese patients: a controlled clinical trial
D. Hofsø[1], T. Jenssen[2], K. Godang[2], R. Sandbu[1], J. Hjelmesæth[1];
[1]Morbid Obesity Centre, Vestfold Hospital Trust, Tønsberg, [2]Department of Medicine, Oslo University Hospital Rikshospitalet, Norway.

Background and aims: The effect of bariatric surgery on insulin secretion has been incompletely explained. The objective of this study was to compare the effect of bariatric surgery and lifestyle intervention on various measures of beta-cell function.

Materials and methods: The study population included 119 morbidly obese patients (mean age 44 years, mean BMI 45.5 kg/m^2, 84 women) without known diabetes classified into normal glucose tolerance (NGT, fasting glucose < 6.1 mmol/l and 2 hour glucose < 7.8 mmol/l) or abnormal glucose tolerance (AGT, fasting glucose ≥ 6.1 mmol/l and/or 2 hour glucose ≥ 7.8 mmol/l), and 29 normal weight controls with NGT. The morbidly obese subjects participated in a one year non-randomised controlled clinical trial (The MOBIL study, ClinicalTrials.gov identifier: NCT00273104) and were treated with either Roux-en-Y gastric bypass (RYGB) surgery (n=64) or intensive lifestyle intervention (ILI) at a rehabilitation centre (n=55). An oral glucose tolerance test (0, 30, and 120 min sampling) was conducted at baseline and after one year, and indices for insulin secretion (Stumvoll first phase) and insulin sensitivity (HOMA S) were calculated from glucose and insulin concentrations. Disposition index (DI), calculated as the product of Stumvoll first phase insulin secretion index and HOMA S, provided a measure of insulin secretion adjusted for insulin sensitivity. Stimulated plasma proinsulin-to-insulin ratio represented an estimate of the efficiency of proinsulin processing in beta-cells.
Results: Mean (SD) weight reduction was 30 (8) % in the RYGB group and 9 (10) % in the ILI group ($p < 0.001$). The figure shows: 1) the hyperbolic imaging of the DI in the subjects with NGT at baseline [curved line; log(HOMA S) = constant + β x log(Stumvoll fist phase) with β (95% CI) = -0.869 (-0.971 to -0.766)]; 2) higher insulin sensitivity after RYGB (dashed line) compared to ILI (solid line) (both $p \leq 0.001$) 3) a more substantial increase in the DI in the RYGB groups than in the ILI groups (both $p < 0.001$); and 4) that the DI in the RYGB NGT group was significantly higher than in the NGT control group ($p < 0.001$). The reduction in mean (SD) proinsulin-to-insulin ratio at 30 minutes was also more pronounced in the RYGB than in the ILI groups: NGT; -1.7 (1.9) % vs. 0.1 (2.1) % ($p < 0.001$); and AGT -4.3 (3.4) % vs. -1.7 (4.6) % ($p = 0.024$).
Conclusion: The improvement in beta-cell function was greater after RYGB than ILI. Post surgery, insulin secretion in the NGT group was when related to insulin sensitivity, even higher than in normal weight NGT controls.



Symbols represent mean values and error bars indicate SEM.
NGT = normal glucose tolerance. AGT = abnormal glucose tolerance.

Plasma FGF21 is increased in response to an oral glucose load post operative in obese subjects undergoing Roux-en-Y gastric bypass

B. Andersen[1], S.H. Jacobsen[2], S. Madsbad[2], D. Worm[2], L.E. Hvolris[2], L. Naver[2], T. Almdal[2], J.J. Holst[3], D.L. Hansen[2], T.R. Clausen[4];
[1]Novo Nordisk A/S, Gentofte, [2]Hvidovre Hospital, [3]University of Copenhagen, [4]Novo Nordisk A/S, Måløv, Denmark.

Background and aims: Fibroblast growth factor 21 (FGF21) is an endocrine hormone involved in regulation of energy homeostasis. Treatment of diabetic mice and diabetic rhesus monkeys with rFGF21 has been shown to lower blood glucose, correct dyslipidemia and increase energy expenditure. The physiological role of FGF21 in humans is not well understood, but FGF21 seems to be increased in states where fat oxidation is required. FGF21 has also been shown to be increased in patients with type 2 Diabetes and in obese subjects. FGF21 is highly expressed in the liver, and to a lower extent in skeletal muscle, pancreas and fat tissue. The basal level of FGF21 seems to be highly controlled by the liver, while FGF21 from the skeletal muscle is increased in response to insulin. In this study, we investigate the fasting levels of FGF21 before and after bariatric surgery, as well as the effect of an oral glucose load (25g and 50g) on plasma FGF21 and insulin before and after the surgery.
Materials and methods: 9 obese, non-diabetics patients (2 males and 7 females, average BMI 46.4; age 26 to 56) underwent Roux-en-Y Gastric Bypass. Fasting plasma FGF21 was measured on three different days before and after surgery. Furthermore, on two different days before surgery and on two different days after surgery, the subjects were given an oral glucose load (25g and 50g glucose) and blood samples were taken starting 30 min before the glucose load followed by 15 min intervals until 180 min after the oral glucose load. Statistics: Student's t-test (paired).
Results: FGF21 in plasma varied in the fasted state from 30 to 1118 pg/ml (258 ± 105 pg/ml) before surgery and from 38 to 1792 pg/ml (399 ± 170 pg/ml) after surgery. In average there was no significant change in fasting plasma FGF21. However, three subjects had a significant ($p=0.024$, $p = 0.013$ and $p=0.035$) increase in fasting plasma FGF21. Furthermore, after the surgery there was a significant ($p=0.0002$) increase in the total plasma insulin concentration during the time course, determined as the area under the curve (AUC) in response to 25g glucose, while there was no change in insulin AUC when 50g glucose was orally administered. The AUC of FGF21 was also significantly increased in response to 25g glucose ($p=0.039$), while the AUC of FGF21 in response to 50g glucose was only borderline significant ($p=0.076$). Plasma FGF21 level peaked at t=120 min and at this time point the plasma levels of FGF21 were significantly increased post surgery, in response to both 25g and 50g glucose ($p=0.015$ and $p=0.008$, respectively).
Conclusion: As previously observed, large individually variations in plasma FGF21 were found. In the nine subjects undergoing Roux-en-Y Gastric surgery, three subjects had a significant increase in fasting FGF21, while six subjects had no change in fasting plasma FGF21. The increase in plasma FGF21 in response to oral glucose post surgery is believed to arise from the stimulatory effect of insulin on the skeletal muscles and could be due to either an increase in muscle insulin sensitivity or the increased insulin release observed in response to glucose (25g). In conclusion, the increase in plasma FGF21 in response to glucose post surgery could play an important role in the positive metabolic outcome of a Roux-en-Y Gastric Bypass.

Mechanisms of early diabetes improvement after biliopancreatic diversion in non-morbidly obese diabetic subjects

B.D. Astiarraga[1], E. Muscelli[1], S. Camastra[1], M. Nannipieri[1], F. Papadia[2], G. Adami[2], N. Scopinaro[2], E. Ferrannini[1];
[1]Department of Internal Medicine, University of Pisa, [2]DISC - Department of surgical sciences and diagnostics, University of Genova, Italy.

Background and aims: A strong improvement or resolution of diabetes has been reported after biliopancreatic diversion (BPD) in diabetic obese patients. On long-term follow up, insulin sensitivity in morbidly obese subjects with or without type 2 diabetes is completely normalised after BPD despite persisting obesity. The early effect of BPD in less obese (BMI 27-35 kg/m2) diabetic subjects is not known. The aim of this study was to assess diabetes control and measure insulin sensitivity early after BPD in diabetic non-morbidly obese patients.
Materials and methods: We studied 12 patients (6 men and 6 women; 56 ± 4 years, BMI range 26.9-33.1 kg/m2) before and 59 ± 24 days after BPD (range 29-101 days). At baseline and following surgery, insulin sensitivity was measured by a 3-hour euglycaemic hyperinsulinaemic (240 pmol.m-2.min-1) clamp.
Results: After surgery, BMI decreased by 13 ± 4% (mean± SD, from 28.8 ± 1.9 to 25.0 ± 2.1 kg/m2, $p = 0.002$). Before BPD, all patients were on oral antidiabetic agents and/or insulin. After surgery, fasting plasma glucose dropped from 12.6 ± 3.1 to 8.3 ± 2.2 mmol/l ($p=0.002$) and HbA1c from 7.93 ± 1.10 to 6.42 ± 0.86%; $p=0.002$. Six patients could be taken off pharmacological treatment. Insulin sensitivity (as the M value) increased from 19.5 ± 3.4 to 34.8 ± 12.0 μmol.min-1.kgFFM-1, $p=0.002$. By simple regression analysis, the improvement in insulin sensitivity was not related to the decrease in BMI or to the time since surgery (p=ns for both).
Conclusion: In diabetic non-morbidly obese patients, biliopancreatic diversion is followed by an early improvement in glycaemic control and insulin sensitivity at a time when weight loss is modest. These findings are compatible with the notion that this type of bariatric surgery impacts on glucose homeostasis by mechanisms at least partly independent of weight loss.

Triple tracer (TT) and double tracer (DT) techniques are reliable methods to estimate glucose appearance in type 1 diabetes

A. Haidar[1], D. Elleri[2], J.M. Allen[1], J. Harris[1], K. Kumareswaran[1], M. Nodale[1], C.L. Acerini[2], M.E. Wilinska[1], N. Jackson[3], A.M. Umpleby[3], M.L. Evans[1], D.B. Dunger[2], R. Hovorka[1];
[1]Institute of Metabolic Science, University of Cambridge, [2]Department of Paediatrics, University of Cambridge, [3]Postgraduate Medical School, University of Surrey, Guilford, United Kingdom.

Background and aims: Measurement of physiological postprandial glucose fluxes in type 1 diabetes could potentially facilitate improvements in modern insulin therapy regimens. TT technique has been proposed to be the gold standard technique to measure postprandial glucose appearance. We validated TT technique and compared it against DT technique in type 1 diabetes.
Materials and methods: Eight young subjects with type 1 diabetes (age 20.8±3.3yrs, BMI 24.0±1.5kg/m2, HbA1c 8.7±1.5%, diabetes duration 10.7±8.9yrs, total daily insulin 0.8±0.2U/kg/day; mean±SD) were studied. From 1800 to 0200 next day, intravenous (iv) 20%dextrose enriched with [U-^{13}C]glucose was infused at a variable rate mimicking meal-derived glucose appearance while iv insulin was administered to achieve basal and postprandial insulin concentration. From 1530 to 0200, primed iv [6,6-$^{2}H_2$]glucose was infused in a manner that mimicked the expected endogenous glucose production. From 1800 to 0200, iv [U-^{13}C; 1,2,3,4,5,6,7-$^{2}H_7$]glucose was infused in a manner that mimicked the expected glucose appearance from a standard meal. The iv dextrose infusion was reconstructed using TT and DT techniques utilizing a modified stochastic Mari model. Plasma glucose was measured every 10-15min. Glucose enrichment was measured by gas chromatography - mass spectrometry every 10 - 30min.
Results: Figure shows actual and reconstructed dextrose infusion rates. The difference between individual actual and individual reconstructed dextrose infusion rates as assessed by the root mean square error (RMSE) was identical for the two methods (8.1± 2.1 vs. 10.6 ± 4.5 µmol/kg/min; TT vs. DT; P = NS, paired t-test). RMSE associated with mean dextrose infusion was 3.0 and 4.2 µmol/kg/min. Overall, 98 ± 9% and 93 ± 16% (P = NS) of the dextrose infusion was recovered.
Conclusion: TT and DT techniques combined with advanced computational methods can measure reliably postprandial glucose appearance in type 1 diabetes. TT tends to outperform slightly DT but the latter benefits from reduced experimental and analytical complexity.

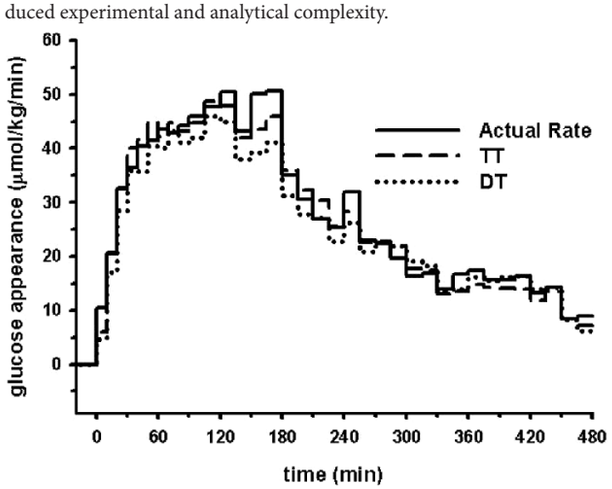

Figure. Actual infusion rate of dextrose and reconstructed infusion rate using triple tracer (TT) and double tracer (DT) techniques (N = 8, mean is shown).

Effects of impaired fasting glucose on the rate of transaldolase exchange

R. Basu[1], C. Barosa[2], V. Pattan[1], P. Reich[1], A. Saad[1], J. Jones[2], A. Basu[1], R. Rizza[1];
[1]Endocrinology, Mayo Clinic College of Medicine, Rochester, USA, [2]Dept of Zoology, University of Coimbra, Portugal.

Background and aims: The deuterated water ($^{2}H_2O$) method is extensively used to measure gluconeogenesis in humans. One of the premises of this method is that there is negligible exchange of the lower three carbons of fructose-6-phosphate and glyceraldehyde-3-phosphate (GAP-3-P) via transaldolase exchange. When this exchange is active, then glucose is labeled on the fifth carbon via simple exchange with labeled GAP-3-P without net gluconeogenic flux. We have recently shown that transaldolase exchange is active in healthy non-diabetic humans and ~30% of the ^{2}H on the fifth carbon of glucose is derived by this mechanism resulting in an overestimation of gluconeogenesis.
Materials and methods: To eliminate possible isotope effects associated with ^{2}H, we assessed the extent of transaldolase exchange with a ^{13}C-tracer where isotope effects are negligible. [1-^{13}C] acetate was infused in 9 subjects with impaired fasting glucose (IFG) and 11 age and BMI matched normal fasting glucose (NFG) subjects. UDP-glucose enrichment was measured following an overnight fast and during a 0.35 mu/kgFFM/min insulin infusion. Somatostatin, glucagon and growth hormone also were infused during the clamp to ensure comparable and equal portal concentrations in both groups. NMR spectroscopy was utilized to measure the ratio of [3-^{13}C] UDP-glucose and [4-^{13}C] UDP-glucose in plasma. In the absence of transaldolase exchange, carbon 4 and carbon-3 are equally labeled resulting in a C3/C4 ratio of 1.0. Transaldolase exchange selectively enriches labeling of carbon 4 resulting in a C3/C4 ratio of < 1.0.
Results: Glucose concentrations in IFG were significantly higher than NFG before (5.9 ± 0.1 vs. 5.4 ± 0.1mmol/L;p<0.005) but matched (6.3 ± 0.0 vs.6.1 ± 0.0mmol/L;p=ns) during the clamp. Insulin concentrations followed a similar trend being higher in the IFG subjects before (49 ± 5.2 vs.34 ± 3.8 pmol/L; p<0.005) but not during (109 ± 6 vs.106 ± 4) the clamp. C-peptide concentrations remained suppressed during the clamp and glucagon concentrations similar in both groups before and during clamp. The ratio of [3-^{13}C] UDP-glucose/[4-^{13}C] UDP-glucose was <1.0 in all subjects but did not differ in the IFG and NFG subjects either in the fasting state (0.68 ± 0.03 vs.0.66 ± 0.04) or during the hyperinsulinemic clamp (0.62 ± 0.04 vs.0.59 ± 0.05).
Conclusions: Transaldolse exchange a) occurs in people with NFG and IFG; b) it is not altered by an insulin infusion; and c) does not differ in NFG and IFG. Thus transaldolase exchange can account for ~35-40% of the deuterium that is present on the carbon 5 following ingestion of $^{2}H_2O$ resulting in a proportionate overestimation of gluconeogenesis. Future studies will be required to determine whether the impact of these processes on the measurement of gluconeogenesis differs in other disease states (e.g. diabetes or obesity) or changes with varying amounts of fast and/or insulin.

Protein and fat modify the glycaemic and insulinaemic responses of a mashed potato-based meal

K.A. Hätönen[1], J. Virtamo[2], J.G. Eriksson[2,3], H.K. Sinkko[1], J.E. Sundvall[2], L.M. Valsta[1];
[1]Department of Lifestyle and Participation, [2]Department of Chronic Disease Prevention, National Institute for Health and Welfare, [3]Department of General Practise and Primary Health Care, University of Helsinki, Finland.

Background and aims: Potatoes, especially mashed potatoes, are known to result in high glycaemic and insulinaemic responses. In most meals, however, potatoes are accompanied by other foods. The objectives of the present study were to investigate how glycaemic and insulinaemic responses to mashed potato meal changed when fat, protein or/and salad were added to the meal and to assess how precise the estimate of GI of the mixed meal by using individual GI values of the components of the meal.
Materials and methods: Eleven healthy subjects (age 36.2±14.1 yrs, BMI 21.3±1.7 kg/m^2) were served the six different mashed potato-based meals (mashed potato alone; with oil; with chicken breast; with salad; with oil, chicken breast and salad; and with oil, chicken breast, salad and rye bread) containing 50-54 g of available carbohydrates once and the reference food (glucose solution) twice in a random order at one-week intervals. Capillary

blood samples were then drawn for 2 h and the glucose and insulin were analysed. The incremental areas under the curve (IAUC), glycaemic index (GI) and insulinaemic index (II) were calculated to estimate glycaemic and insulinaemic responses.
Results: The 2-hour glycaemic responses to six mashed potato-containing meals varied more than two-fold. The glycaemic index (GI) of pure mashed potato was 108, whereas combined with protein, fat and salad, it was only 54. The latter GI also differed considerably from its predicted value of 103, which was based on the individual GIs of the components of the meal. The insulinaemic indices (II) of mashed potato-based meals varied between 94 and 148. Protein in the meal increased the insulinaemic response and fat diminished it. However, the insulinaemic response to mashed potato with protein and fat was lower than for mashed potato alone.
Conclusion: The protein, fat and salad content of a meal exert considerable influence on the glycaemic and insulinaemic responses to the meal. The estimate of the GI of a mixed meal by the calculation of its components is imprecise.

Glucose appearance of large slowly-absorbed evening meal containing complex carbohydrates (CHO) in type 1 diabetes (T1D)
D. Elleri[1], J. Harris[1], K. Kumareswaran[1], J.M. Allen[1], A. Haidar[1], M. Nodale[1], A. Swamy[1], M.E. Wilinska[1], J. Weston[2], C.L. Acerini[1], N. Jackson[3], A.M. Umpleby[3], M.L. Evans[1], D.B. Dunger[1], R. Hovorka[1];
[1]University of Cambridge, [2]Addenbrooke's Hospital, Cambridge, [3]University of Surrey, Guildford, United Kingdom.

Background and aims: Many young patients with T1D report difficulty in adjusting the dose and timing of insulin when eating complex meals containing large CHO loads. Using novel methodology, we estimated appearance of complex and simple CHO in young people with T1D.
Material and methods: Eight subjects with T1D (age 20.8±3.3yrs, BMI 24.0±1.5kg/m^2, A1c 8.7±1.5%, diabetes duration 10.7±8.9yrs, total daily insulin 0.8±0.2U/kg/day; mean±SD) were studied on 2 separate visits at a clinical research facility. On both visits, from 1000 until 1730, variable intravenous (iv) insulin was infused to achieve normoglycaemia. On Visit 1 the subjects fasted until 1800 when they consumed a slowly absorbed pasta meal (CHO:protein:fat 121:35:30g; sugars:starch 13:107g; glycaemic load 54) enriched with [U-^{13}C]glucose and until 0200 next day iv insulin was infused to mimic prandial bolus of rapid-acting insulin (14±2U) and basal insulin delivery (0.9±0.3U/h). On Visit 2 identical iv insulin was given but, instead of the meal, variable iv 20%dextrose enriched with [U-^{13}C] glucose was infused to reproduce the plasma glucose profile observed on Visit 1. Iv infusion of [6,6-$^2H_2$] glucose and [U-^{13}C;1,2,3,4,5,6,6-$^2H_7$] glucose were given on both visits in a fashion to mimic endogenous glucose production (EGP) and glucose appearance of simple and complex CHO from the meal (Ra_meal), respectively. Plasma glucose enrichment with the 3 tracers was measured by gas chromatography mass spectrometry. Total glucose appearance (Ra_total) on Visit 1 was estimated by double tracer approach. Ra_meal on Visit 1 was calculated as "Ra_total - EGP", where EGP was obtained from Visit 2 and estimated by double tracer approach. Glucose appearance of simple CHO (Ra_meal_simple) on Visit 1 was estimated by triple tracer approach.
Results: Ra_meal extended over 8 hours with a sustained plateau of 30µmol/kg/min over the first 3 hours, see Figure; 25% of the Ra_meal appeared 88±21 min after meal consumption, 50% at 175±39 min, and 75% at 270±54 min. Ra_meal_simple was significantly faster with 25, 50 and 75% of the total appearance at 39±13, 84±30 and 159±42 min respectively ($p<0.0001$, paired t-test). Bioavailability of simple CHO did not differ from that of complex and simple CHO (108±25 vs 101±14%, $p=0.30$).
Conclusions: Glucose appearance after consumption of a large slowly-absorbed evening meal is sustained over 1-3hours and may extend up to 8hours. This finding may have implications on prandial insulin dosing in T1D suggesting a need for dual and/or delayed insulin doses.

Figure. Rate of appearance of complex and simple carbohydrates (black line, 120g CHO) and simple carbohydrates only (gray line, 13g CHO) from a slowly-absorbed meal [mean (SD)]

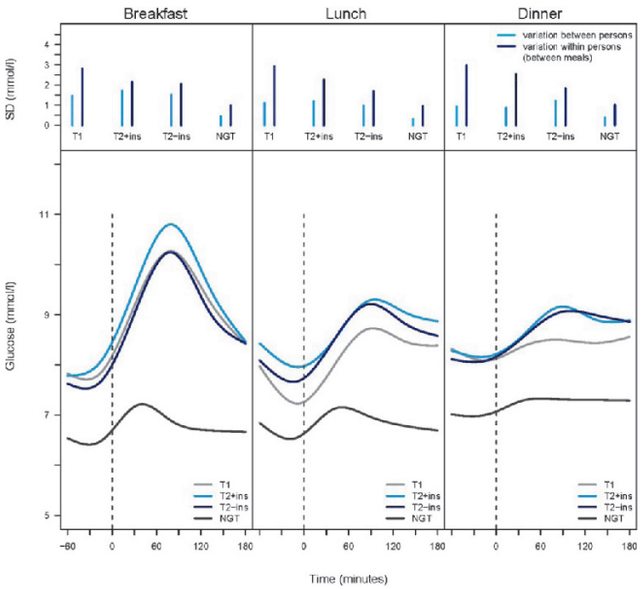
Can we identify typical glycaemic patterns around meals for individuals with or without diabetes? The ADAG Study
R. Borg[1], A.C. Jensen[1], B. Carstensen[1], J. Kuenen[2], R.J. Heine[2], H. Zheng[3], D.M. Nathan[3], D.R. Witte[1];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]VU Medical Center, Amsterdam, Netherlands, [3]Diabetes/Biostatistics Department, MGH/Harvard Medical School, Boston, USA.

Background and aims: Postprandial glucose concentrations are determined by factors such as meal composition, physical activity, glucose tolerance, and glucose lowering therapy. Glucose profiles under real-life circumstances are not widely studied. The aim of this study was to describe the glucose profiles among persons with type 1 (T1DM), type 2 (T2DM) and in healthy control subjects (non-DM) based on intensive continuous glucose monitoring (CGM).
Materials and methods: In the A1c Derived Average Glucose (ADAG) study, participants underwent intensive glucose monitoring using CGM for approximately 13 days over a 3 month period. The study included 264 participants with T1DM, 99 with T2DM without insulin treatment, 60 with T2DM with insulin treatment, and 80 healthy controls. Multi-level mixed models with 5-point splines were fitted for 4-hour time windows around the 3 main meals of the day for each subgroup accounting for the variation between and within individuals. Mean and peak glucose levels were modelled as a linear function of age, BMI, HbA_{1c}, and the glucose reference value one hour before each meal.
Results: Glucose levels following breakfast were higher than those following lunch and dinner. Glucose concentrations peaked earlier after breakfast than after either of the other meals. The time to glucose peak value for T1DM after breakfast was 80 minutes, after lunch 95 minutes, and after dinner 100 minutes. Times to peak for T2DM without insulin treatment were 70, 85 and 100 minutes respectively. Non-DM individuals naturally presented much lower peak values, but also showed significantly shorter time to peak (50-85 minutes). The prandial glucose curves and the inter- and intra-individual variation are illustrated in the Figure.
Conclusion: Based on intensive continuous glucose monitoring in patients with T1DM, T2DM and healthy controls under real life circumstances, we found that glucose excursions after meals are largest in DM, compared to non-DM, both in terms of peak value and time to peak. The three diabetic subgroups presented similar patterns. We found considerable day to day variability in meal glucose excursions within individuals with a a stable treatment regime. This variability was larger than the variation between individuals within the same clinical subgroup. Overall, breakfast was followed by higher glucose levels than either lunch or dinner.



Bottom: Glucose levels as a function of time, age, BMI and HbA1c around the main meals of the day for the 4 clinical patient groups. The dotted line illustrates meal time.
Top: The variability (SD) of the peak glucose level within and between persons.

Analysis of the control exerted by glucokinase and glucose-6-phosphatase on glycerol metabolism of liver cells using different systems biology frameworks

S. Marin, A. Miranda, V.A. Selivanov, I. Marin, J.J. Guinovart, M. Cascante;
Biochemistry and Molecular Biology, Universitat de Barcelona, Spain.

Background and aims: The metabolic flux profile of a cell is the result of the whole of cellular processes, and is characteristic of its phenotype. Stable isotope tracer data is normally used to reveal the metabolic flux profile in cells under various conditions studied. Models of hepatic liver cells are very useful to understand the metabolic dysregulations associated to pathologies such as diabetes, due to its key role in glucose homeostasis. Glucokinase (GK) and glucose-6-phosphatase (G6Pase), the enzymes that catalyze the first futile cycle in glycolysis, have been proven to have a key role in the development of MODY2 and GSD-1 diseases. Our goal was to know if the GK-G6Pase futile cycle compromises the metabolism of glycerol, the main gluconeogenic substrate of liver cells in long fasting. The use of softwares capable of integrating all generated data allows a better extraction of relevant biological information. Thus, another aim of this study is to compare the metabolic flux profile obtained in these experiments using Mass Isotopomer Distribution Analysis (MIDA) and Isodyn, a home-made software developed for the quantification of metabolic fluxes.
Materials and methods: Primary cultures of rat hepatocytes treated with increasing doses of adenovirus encoding the rat liver GK or G6Pase, are incubated for 3h with 10mM glycerol 50% enriched in [U-13C]-glycerol. The biochemical concentrations and isotopomer patterns of glucose, lactate and glycogen are analyzed at the end of incubation. The obtained data are analyzed using MIDA and Isodyn. Using the framework of Metabolic Control Analysis, the control coefficients of GK and G6Pase over the different quantified fluxes are estimated.
Results: So far, overexpression of GK and G6Pase induced different biochemical concentrations and isotopomer patterns, which correlate with the increase of enzyme activity. The MIDA analysis of the experimental data allowed us to calculate the fluxes of glucose, glycogen and lactate synthesis from glycerol at the different enzyme activities.
Conclusion: The analysis of functional organization of metabolism based on the isotopic isomer distribution allows us to estimate the changes associated with a perturbation of the metabolic network in the central carbon metabolism. The results so far indicate that glycerol metabolism induces metabolic flux distributions that are dependent on the activity of the futile GK-G6Pase cycle. The modifications performed in our software Isodyn will make it a model valid for modelling liver cell, extracting relevant biological information and being able to integrate all generated data.

Metabolic and anti-inflammatory benefits of eccentric endurance exercise

S. Beer[1,2], P. Rein[1,2], C.H. Saely[1,2], A. Vonbank[1,2], V. Kiene[1], S. Aczel[1], T. Bochdansky[3], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Prinicpality of Liechtenstein, Triesen, Liechtenstein, [3]Academic Teaching Hospital Feldkirch, Austria.

Background and aims: The interplay of muscle contraction with an external force can result in one of three types of muscle activity: shortening or "concentric" when muscle contraction is stronger than the external force; lengthening or "eccentric" when the external force is stronger; and isometric when both forces are equal. Eccentric endurance exercise (e.g. hiking downwards) is less strenuous than concentric exercise (e.g. hiking upwards) but its metabolic effects are largely unknown. In the present study we therefore aimed at elucidating the metabolic effects of this training modality.
Materials and methods: We allocated 93 healthy sedentary individuals to an exercise intervention program, consisting of hiking downwards a pre-defined route in the Austrian Alps over two months. For the opposite way, a cable car was used where compliance was recorded electronically. The difference in altitude was 540 metres; the distance was covered three to five times a week. A matched group of 25 individuals served as a control group. Fasting and postprandial metabolic profiles were obtained at baseline and after the two months period.
Results: Compared with baseline, eccentric exercise significantly lowered fasting glucose (97±15 vs. 94±9mg/dl; p=0.025) and glucose tolerance (239±50 vs. 217±47 $mg^{*}dl^{-1}\ h^{-1}$; p<0.001), whereas both were unchanged in the control group (p=0.265 and p=0.231, respectively). Body mass index (27.7±4.4 vs. 27.4±4.3 kg/m^2; p=0.003) and C-reactive protein (0.27±0.42 vs. 0.23±0.25 mg/dl; p=0.031) also significantly declined in the eccentric exercise group but not in the control group (p=0.053 and p=0.864, respectively). Furthermore, eccentric exercise significantly lowered triglyceride tolerance (1959±1330 vs. 1670±1085 $mg^{*}dl^{-1}\ h^{-1}$; p=0.003) and the postprandial leukocyte count (68.8±11.6 vs. 66.5±13.6 $G^{*}L^{-1}\ h^{-1}$; p=0.031), whereas both were unchanged in the control group (p=0.819 and p=0.600, respectively).
Conclusion: Eccentric exercise is a promising new exercise modality with favourable metabolic and anti-inflammatory effects. This moderately strenuous training option could become especially important in patients with diabetes, because a large proportion of these patients suffer from comorbidities conferring a low tolerance for high-intensity training protocols.

682

Comparison of Square-Wave Endurance Exercise Test (SWEET) training with endurance training targeted at the level of maximal lipid oxidation in type 2 diabetics

J.-F. Brun, J. Maurie, E. Jean, A.-J. Romain, J. Mercier;
Metabolic Unit, INSERM ERI 25, Montpellier, France.

Background and aims: Both low and high intensity exercise have been demonstrated to be useful in the management of type 2 diabetes. Their effects are likely to be different and complementary. We aimed at comparing in type 2 diabetes a protocol of endurance training precisely targeted at the power intensity of maximal lipid oxidation (LIPOXmax) with a protocol combining resistance and endurance training (Square-Wave Endurance Exercise Test (SWEET) training).
Materials and methods: 63 type-2 diabetics (age 52.6±1.5 years; BMI 32.7±0.7) were divided into 3 groups matched for age, BMI, and HbA_{1c} and were compared over a period of 3 months, without nutritional intervention: 39 were trained at the LIPOXmax determined with exercise calorimetry, 12 were submitted to a SWEET training, and 12 untrained patients served as controls.
Results: After 3 months, both procedures increased maximal aerobic capacity (VO2max) (SWEET training +42±16.4% p=0.027 vs LIPOXmax training (+14±4.09% p=0.0011). The effect of SWEET training on VO2max was stronger than that of LIPOXmax training (p=0.0016). SWEET training reduced resting systolic blood pressure (-12.08±5.17 mmHg p=0.040) and total cholesterol (-0.74±0.33 mmol/l p=0.049), while LIPOXmax training did not. Both procedures decreased weight and BMI. By contrast, the LIPOXmax training improved the ability to oxidize lipids (maximum lipid oxidation rate +53 ± 13.53 mg/min p=0.0005) shifted it to a higher power intensity (+20.9 ± 4.29

watts p=0.00002), decreased fat mass (- 1±0.37 %; p=0.012), increased fat-free mass (+1 ±0.37 % p=0.012), decreased waist circumference (-3.76±0.99 cm p=0.0007) and hip circumference (-2.18±0.78 cm p=0.009) while SWEET training did not significantly affect any of those parameters. Over this short period the effects of training on HbA1c were significant in the LIPOXmax group (-0.15±0.07% p=0.044) but not in the SWEET group.
Conclusion: This study shows that SWEET training improves aerobic working capacity, blood pressure and lipid profile, while low intensity endurance training (LIPOXmax training) improves the ability to oxidize lipids at exercise, increases fat free mass, decreases fat mass and decreases HbA_{1c}. The benefits of these two procedures are thus quite different and both are probably interesting to associate in the management of type 2 diabetes.

683

Objectively measured sedentary behaviour and physical activity in relation to adiposity in a multi-ethnic population at risk of developing diabetes

V.E. Kumar[1], T. Yates[1], M.J. Davies[1], E.G. Wilmot[1], K. Khunti[2];
[1]Cardiovascular Sciences, University of Leicester, [2]Health Sciences, University of Leicester, United Kingdom.

Background and aims: Sedentary behaviour (SB), typically measured indirectly (e.g. through self-reported TV viewing), is increasingly reported to be an important factor in the obesity epidemic, independent of physical activity. However data using objective measures of sedentary behaviour are lacking in high-risk populations. We aim to test the hypotheses that in a population identified with a high risk of diabetes, SB and light-intensity physical activity (LPA) are more important determinants of obesity than moderate-vigorous physical activity (MVPA).
Methods and materials: Participants with a high risk of diabetes, identified with the validated Leicester risk score, were recruited from primary care, Leicester, UK. SB, LPA and MVPA were measured objectively using validated accelerometers (GT3X, Actigraph), worn for 7 consecutive days. Freedson's validated cut-off points were used to calculate SB (<100 counts/min), LPA (100-1,951 counts/min) and MVPA (1,951 counts/min). Basic anthropometric measurements were conducted using standardized methods. Following best practice, total (non-sleeping) sedentary time was calculated by deducting non-wear time estimated using standardized criteria. Linear regression analysis models examined the effects of SB, LPA and MVPA on waist circumference and BMI.
Results: 89 participants were used in the analysis; mean age = 62.7 years (S.D. 9.3), Mean BMI = 33.5 kg/m^2 (S.D. 5.6), mean waist circumference = 105.5cm (S.D. 11.8). Mean daily sedentary time = 550min (S.D. 115), mean daily LPA = 248min (S.D. 73) and mean MVPA = 19min (S.D 16). After adjusting for confounders, sedentary time had the greatest effect on both waist circumference and BMI with standardised beta coefficients of 0.40 (SE = 0.18; p=0.03) and 0.31 (SE = 0.15; p=0.04) respectively (see Table 1).

Table 1 - association between different categories of activity and adiposity

	Waist circumference		**BMI**	
Sedentary time	*Standardised beta coefficient* ± S.E.	*P value*	*Standardised beta coefficient* ± S.E.	*P value*
Model 1[a]	0.57 ± 0.16	0.001	0.40 ± 0.13	0.003
Model 2[b]	0.40 ± 0.18	0.03	0.31 ± 0.15	0.038
Light intensity physical activity		P value		*P value*
Model 1[a]	-0.32 ± 0.12	0.008	-0.23 ± 0.09	0.019
Model 2[b]	-0.24 ± 1.17	0.048	-0.18 ± 0.1	0.071
moderate-to vigorous-intensity physical activity (MVPA)		P value		*P value*
Model 1[a]	-0.33 ± 0.1	0.001	-0.20 ± 0.08	0.017
Model 2[c]	-0.22 ± 0.11	0.051	-0.12 ± 0.09	0.215

[a]adjusted for wear time, gender, age, ethnic origin & smoking status
[b]adjusted for wear time, gender, age, ethnic origin, smoking status & MVPA
[c]adjusted for wear time, gender, age, ethnic origin, smoking status & sedentary time

Conclusion: Our findings conclude that in a population with high risk of diabetes, identified through a validated risk score, adiposity is more strongly linked with time engaged in SB than MVPA. Hence, diabetes prevention programmes aimed at weight loss may be more effective if the emphasis is shifted from traditional MVPA goals to reducing SB, such as sitting. If these findings are confirmed by appropriately designed intervention studies, they could have dramatic implications on future public health recommendations.

684

Situation of exercise therapy for patients with diabetes mellitus in Japan - a joint project with the Japan Medical Association

Y. Sato[1], H. Sone[2], M. Kobayashi[3], R. Kawamori[4], Y. Tamura[4], Y. Atsumi[5], Y. Oshida[6], S. Tanaka[7], S. Suzuki[8], S. Makita[9], I. Ohsawa[1], Research Committee for the Establishment of Therapeutic Exercise for Diabetics of the Japan Diabetes, S. Imamura[10], T. Watanabe[1];
[1]Aichi Gakuin Univ., Nisshin, [2]Univ. of Tsukuba, Mito, [3]Univ. of Toyama, [4]Juntendo Univ., Tokyo, [5]Saiseikai Central Hosp., Tokyo, [6]Nagoya Univ., [7]Osaka Sangyo Univ., Daito, [8]Ohta General Hosp., Koriyama, [9]Saitama Medical Univ., Hidaka, [10]Japan Medical Association, Tokyo, Japan.

Background and aims: Regardless of the well-known health-promoting benefits of exercise, it is actually less prescribed than diet and drug therapy in the clinical practice. In addition, up till now a national survey on the present situation of exercise therapy for patients with diabetes mellitus has not been conducted in Japan. Therefore, our committee in the Japan Diabetes Society joined the Japan Medical Association to conduct the first nationwide survey that aimed to investigate the actual situation of exercise therapy for diabetic patients in Japan.
Materials and methods: Questionnaires concerning the practice and adopted systems of exercise guidance for diabetic patients were mailed to randomly selected diabetologists (n = 600) and non-specialist physicians (n = 600). Responses were obtained from a total of 403 doctors (response rate of 33.6%), 275 diabetologists (50.3 ± 10.6 years of age; mean ± SD) and 128 non-specialist physicians (52.4 ± 9.8 years of age). Collected data were analyzed using the chi-square test, the Fisher's exact test, and the Student's t-test.
Results: While only 18% of the non-specialist physicians were found to carry out special clinic for diabetic patients, this rate was 64% among diabetologists ($p < 0.001$). Diabetologists (78%) and non-specialist physicians (67%) were found to provide dietary guidance to almost all patients at the initial visit to the clinic; however, exercise guidance to the patients at their initial visit was performed by only about 40% of both categories of doctors. In addition, 10% of the diabetologists and 18% of the non-specialist physicians did not provide exercise guidance to their patients. On the other hand, while about 60% of the diabetologists provided exercise prescription and group or personal guidance to the patients, the rate among non-specialist physicians was about 30%. Less than 20% of the diabetologists answered to have physical exercise educators in their clinics. Another finding of this survey was that 46% of the diabetologists and 40% of the non-specialist physicians have no appropriate guidelines for exercise therapy of diabetic patients. Taking into consideration the main problems related with the implementation of exercise therapy by the doctors (i.e., no additional consultation fee for exercise guidance, lack of time to provide guidance, absence of specialized physical educator); it becomes clear that an early improvement of this situation is challenging.
Conclusion: The present nationwide survey on the situation of exercise therapy for diabetic patients revealed that, in Japan, (1) the proportion of dietary guidance is markedly higher than the proportion of exercise guidance and (2) significant differences between diabetologists and non-specialist physicians do exist. These results suggest that, as exercise guidelines are more realistic and effective than other demands of doctors, preparation of proper exercise guidelines for exercise therapy of diabetic patients is necessary.

Associations between cardio-respiratory fitness and glycaemic indices in a Danish population at high diabetes risk

A.-L.S. Hansen[1], D. Vistisen[1], J.W. Helge[2], M. Aadahl[3], A. Sandbaek[4], D.R. Witte[1];
[1]Epidemiology Group, Steno Diabetes Center A/S, Gentofte, [2]Department of Biomedical Sciences, University of Copenhagen, [3]Research Centre for Prevention and Health, Glostrup, [4]Department of General Practice, Institute of Public Health, Aarhus, Denmark.

Background and aims: High cardio-respiratory fitness is known to be associated with several health-outcomes such as low risk of cardiovascular diseases and all cause mortality. Furthermore, studies have shown that cardio-respira-

tory fitness is positively related to insulin sensitivity. The aim of this study was, to compare the strength of the association between cardio-respiratory fitness and multiple glycaemic indices in a population at high diabetes risk, taking into account obesity.

Materials and methods: Data from participants of the ADDITION-PRO study (cross-sectional study, subjects at high diabetes risk identified by a stepwise screening programme) are included in the analysis. Associations between fitness level and glycaemic indices are examined using linear regression models. Fitness levels were derived from estimated maximal oxygen consumption, VO_2max (mlO_2 x kg^{-1} x min^{-1}), based on the relationship between heart rate and physical activity intensity during an 8 minutes sub-maximal step test. Homeostatic model of assessment (HOMA2) was used to calculate insulin resistance (HOMA2-IR) and beta cell function (HOMA2-B). Insulin sensitivity was estimated by the Insulin Sensitivity Index (0,120). Pancreatic response was estimated by disposition index. The analyses were adjusted for sex, age, and waist circumference, WC.

Results: Data from the first 87 subjects, aged 52-77 years, 63% men, were included in the analyses. Mean VO_2max was: 32 (men) and 27 (women) mlO_2 x kg^{-1} x min^{-1}. The changes in standardized estimates of glycaemic markers per one standard deviation (SD) change in the estimated VO_2 max (partial correlation coefficients) are presented in table 1.

Conclusion: In this high diabetes risk population with low fitness levels, higher cardio-respiratory fitness was associated with better insulin sensitivity. In an age- and sex-adjusted model estimated VO_2max showed a positive association with Insulin Sensitivity Index and a negative association with HOMA2-IR reflecting the association of fitness and peripheral insulin sensitivity and hepatic insulin resistance, respectively. WC abolished these associations. However, this may be due to over-adjustment. Pancreatic response determined by disposition index and beta-cell function estimated by HOMA2-beta showed no associations with fitness level.

Table 1. Associations between estimated VO_2max and glycaemic indices

N=87	HbA1c	HOMA2-IR	HOMA2-B	Insulin sensitivity index (0,120)	Disposition index
Estimated VO_2max (mlO_2 x kg x min) adjusted for age, sex	-0.13 (-0.36;0.11)	-0.32 (-0.55;-0.10)*	-0.19 (-0.43;0.04)	0.33 (0.10;0.55)*	0.03 (-0.21;0.27)
Estimated VO_2max (mlO_2 x kg x min) adjusted for age, sex, waist circumference	-0.02 (-0.26;0.22)	-0.08 (-0.28;0.11)	-0.05 (-0.29;0.18)	0.09 (-0.10;0.29)	-0.05 (-0.30;0.20)

Different responses of adipocytokine, free fatty acid, and insulin sensitivity to diet or exercise induced weight loss and maintenance in type 2 diabetes

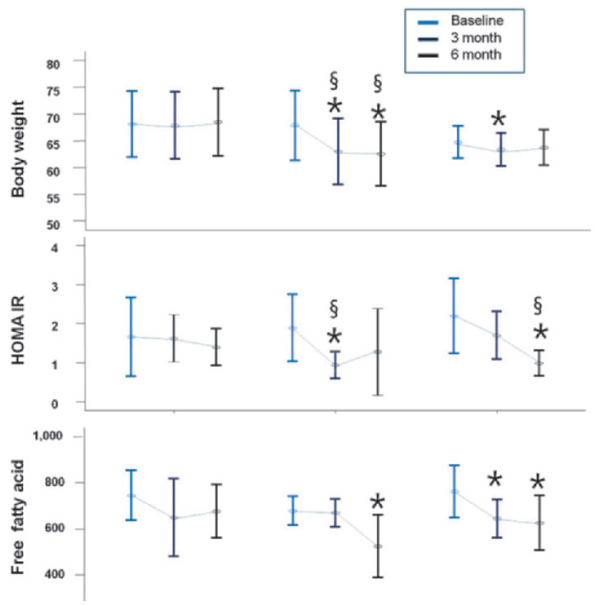
K.A. Han, K. Pak, K.W. Min, H.K. Lee;
Department of Internal Medicine, Eulji university, Seoul, Republic of Korea.

Background and aims: The aim of the study was to compare the effects of diet or exercise induced weight loss and maintenance trial on free fatty acid, adipokine, and inflammatory cytokines in type 2 diabetes.

Materials and methods: Total 39 women with type 2 diabetes were randomly assigned to control (C, N=14), diet (D, N=11), exercise (E, N=14) and completed the 3 month weight loss program, and then followed by body weight(BW) maintenance for 3 months. The restriction of calorie intake (< 1400 kcal/day) was done for D, walking for 60 minutes at moderate intensity (3.6 to 5.2 METs) five times a week for E. Diet was monitored with 3 day dietary record, and physical activity with accelerometer. We assessed anthropometric parameters, free fatty acid (FFA), high-sensitive C-reactive protein(hsCRP) and intrleukin 6(IL6) and adiponectin leptin ratio(ALr) and homeostasis model assessment of insulin resistance (HOMA- IR) at baseline, 3 months, and 6 months.

Results: At baseline, the participants' age was 54.9±7.4 years and BMI was 27.2±3.4kg/m^2 (BW: 66.8±8.7kg) without the differences across 3 groups. Body weight (BW) decreased from baseline by 4.9±1.5kg in D, and by 1.4 ±1.6 kg in E during weight loss program (p=0.001, p=0.008), and didn't change significantly during following maintenance in both intervention groups period. Increased ALr and decreased HOMA-IR were found only in D at 3 months (p=0.004, p=0.06 respectively), which didn't sustain until 6 months. HOMA-IR decreased gradually and made significant difference only at 6 months in E(P=0.04). ALr changed with BW and HOMA-IR during first 3 months(r=-0.748, p<0.001; r=-0.432, p=0.006, respectively). Within group analysis showed that FFA did not change from baseline at 3 months and decreased at 6 months in D, but decreased at 3 month and sustained until 6 month in E. FFA changed with relation to hsCRP at 3 months, and to IL6 at 6 months in all subjects((r=0.428, P=0.007: r=0.323, P=0.045, respectively).

Conclusion: These results suggest that diet induced weight loss resulted in favorable effects on insulin resistance and adipokines which were not prominent during weight maintenance. Exercise induced the improvement of insulin resistance slower than diet without relation to adipokines and body weight. On the other hand, FFA improved earlier in exercise than in diet. The lifestyle modification for 6 months was not sufficient to change the inflammatory cytokines in type 2 diabetes.



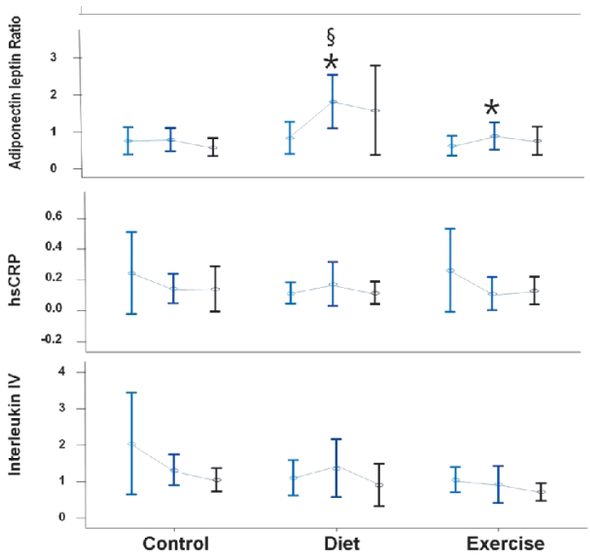


Fig. The changes of body weight, adipocytokines, and free fatty acid, and homeostasis model assessment of insulin resistance at baseline, 3 months (immediate after weight loss), and 6 months (after weight maintenance) during lifestyle modification.

§ Significant (p<0.01) compared to control group (ANOVA)
* Significant (p<0.05) from baseline (between group analysis)

Pioglitazone increases the aerobic capacity with improved skeletal muscle energetics in patients with insulin resistance

T. Yokota[1], S. Kinugawa[1], K. Hirabayashi[1], T. Suga[1], S. Takada[1], M. Takahashi[1], S.A. Mochamad[1], T. Ono[1], N. Morita[2], K. Okita[3], H. Tsutsui[1];
[1]Cardiovasucular Medicine, Hokkaido University Graduate School of Medicine, Sapporo, [2]Hokkaido University of Education, Iwamizawa, [3]Hokusho University, Ebetsu, Japan.

Background and aims: Low aerobic capacity is a strong predictor for cardiovascular morbidity and mortality in insulin resistance and type 2 diabetes. Recent study reported that pioglitazone, known as peroxisome proliferator-activated receptors (PPARs)-γ agonist, enhances the expression of genes involved in mitochondrial function and fatty acid oxidation in patients with type 2 diabetes. Skeletal muscle energy metabolism is an important determinant of aerobic capacity. Therefore, the aim of the study was to investigate the effect of pioglitazone on aerobic body (whole-body oxidative capacity) in relation to alteration in skeletal muscle energy metabolism.
Materials and methods: Fourteen male insulin-resistant subjects with no habitual exercise participated in the study before and after 3 months of 15 mg/day pioglitazone treatment. Blood was corrected in after 10 hrs fasting. To assess the aerobic capacity, peak oxygen uptake (peak VO_2) and anaerobic threshold (AT) during incremental exercise testing with cycle ergometer were measured. Body composition was measured by BOD POD, an air displacement plethysmograph and the aerobic capacity was normalized to lean body mass to eliminate the influence of altered body composition. Daily physical activity was monitored for a week before and after treatment by a pedometer with an accelerometry sensor. To assess the skeletal muscle energy metabolism, high-energy phosphates metabolites at rest and during plantar flexion exercise with a constant load of 20% one-repetition-maximum for 4 minutes were measured using ^{31}P-magnetic resonance spectroscopy (MRS). Intramyocellular lipid (IMCL) content was also measured using ^{1}H-MRS. Data are expressed as mean ± SD.
Results: Pioglitazone significantly decreased fasting blood glucose (116 ± 18 vs. 106 ± 13 mg/dL, P < 0.01), insulin (13.7 ± 9.8 vs. 6.7 ± 2.7 μIU/mL, P < 0.05), and HOMA-IR (4.0 ± 3.3 vs. 1.8 ± 0.8, P < 0.05). Body weight and %Fat were comparable before and after treatment. Daily physical activity, assessed by daily steps and movement-related calorie consumption were not altered before and after treatment. Peak VO_2 (35.1 ± 5.9 vs. 38.2 ± 5.2 mL/kg/min, P < 0.01) and AT (18.3 ± 3.0 vs. 20.2 ± 3.3 mL/kg/min, P < 0.05) normalized to lean body mass were significantly increased after treatment of pioglitazone. Phosphocreatine (PCr) loss during plantar flexion exercise was significantly decreased after treatment of pioglitazone (0.293 ± 0.112 vs. 0.256 ± 0.086, P < 0.05), suggesting increased energy reserve. Moreover, IMCL content tended to be decreased after treatment of pioglitazone (4.5 ± 1.3 vs. 3.3 ± 2.1 mmol/kg wet weight, P = 0.06).
Conclusion: Pioglitazone increased the aerobic capacity with improved skeletal muscle high-energy phosphates metabolism and decreased IMCL content in patients with insulin resistance without alteration in physical activity. These findings raise the possibility that pioglitazone might increase the aerobic capacity, at least in part, through improvement of fatty acid oxidation in skeletal muscle.

688

Physical activity may offset pregnancy-related insulin resistance

A. Gradmark[1], J. Pomeroy[2], F. Renström[1], S. Steiginga[1], A. Wright[3], S.E. Kahn[4], I. Mogren[5], M. Domellöf[6], P.W. Franks[1];
[1]Medicine, GECRG, Public Health and Clinical Medicine, Umeå, Sweden, [2]NIDDK/NIH, Diabetes Epidemiology and Clinical Research Section, Phoenix, USA, [3]MRC Human Nutrition Research, Cambridge, United Kingdom, [4]Medicine, Division of Metabolism, Endocrinology and Nutrition, Seattle, USA, [5]Department of Clinical Sciences, Obstetrics & Gynecology, Umeå, Sweden, [6]Department of Pediatrics, Umeå, Sweden.

Background and aims: Insulin resistance increases in pregnancy, which is often compensated for by increase in insulin secretion in order to maintain normoglycemia. Physical activity improves insulin sensitivity outside pregnancy, but little is known of whether physical activity can offset pregnancy-related insulin resistance, which was the focus of this study.
Materials and methods: Thirty-two women in gestational weeks 28-32 from Västerbotten, Sweden were recruited through advertisement. Glucose and insulin levels were measured fasting and at 30, 60, and 120 minutes during a 75g oral glucose tolerance test. Insulin resistance was estimated using the homeostasis model assessment of insulin resistance (HOMA-IR). Insulin secretion was estimated via early insulin response (EIR) and the oral disposition index (DI_O). Resting metabolic rate (RMR) and total energy expenditure (TEE) were directly measured using indirect calorimetry and doubly-labeled water, respectively, from which physical activity energy expenditure (PAEE) was calculated. Heart rate measured with the Actiheart (CNT Ltd, Papworth, UK) was used to calculate time spent in moderate-to-vigorous physical activity and also to estimate sedentary time (min/day). Associations between gestational PAEE, sedentary time and insulin sensitivity or secretion were determined using generalized linear regression (SAS v9.1, Cary, NC).
Results: Total daily PAEE was positively associated with DI_O after adjustment for maternal age, height, and weight. Time spent in moderate-to-vigorous activity was not associated with any of the estimates of insulin sensitivity or secretion, but sedentary time was negatively associated with EIR.
Conclusions: Insulin resistance typically increases during pregnancy and raises the risk of gestational diabetes mellitus. These data indicate that this may be ameliorated by maintaining high levels of physical activity. Specifically, our findings suggest that minimizing time spent in sedentary behaviors might be the focus of future interventions aimed at preventing gestational diabetes mellitus.

Table 1. Tests of association between physical activity and estimates of insulinemia during pregnancy (28-32 weeks gestation)

	PAEE (kcal/day)		Sedentary time (minutes/day)		Moderate - Vigorous time (minutes/day)	
Women (n = 32)	Partial r^2	β	Partial r^2	β	Partial r^2	β
HOMA-IR[a]	0.009	-0.14	0.03	0.13	0.04	-0.19
EIR[a]	0.002	-0.06	0.15*	-0.35	0.0017	0.03
DI_O[a]	0.14*	0.38	0.008	0.19	0.03	0.13

Adjusted *p< 0.05. Multiple testing was adjusted for using the Holm procedure; Partial r^2 = variance in outcome explained by physical activity variable; β = standardized beta coefficient; PAEE = Physical activity energy expenditure; HOMA-IR = Homeostasis model assessment of insulin resistance; EIR = Early Insulin Response; DI_O = Oral disposition index; a. Impact of exercise on continuously-monitored glucose levels in type 1 diabetes patients >14 years of age on insulin pump therapy

A.M. Gomez, C.M. Gomez, A. Veloza, O. Muñoz, C.P. Rubio;
Endocrinology, Hospital Universitario San Ignacio, Bogota, Colombia.

Background and aims: Exercise is a risk factor for hypoglycemia in type 1 diabetes, but the relationship between exercise intensity and duration to the onset and severity of hypoglycemia is unclear. Here we compared the impact of standardized morning and afternoon exercise on glycemic control for 36 h post-exercise using a continuous glucose monitoring (CGM) system in type 1 diabetes patients >14 years old.
Materials and Methods: Thirty-two subjects on CGM sensor-augmented pump therapy (Paradigm REAL-Time System, Medtronic Diabetes, Northridge, CA, USA) were evaluated at the Diabetes Clinic of Hospital San Ignacio, Bogotá, Colombia. They participated in morning and afternoon exercise sessions maintaining a heart rate of 50-70% of maximum, for 4 15-min bouts of treadmill walking with 5-min breaks between the bouts. Capillary blood glucose values were measured 4 times during exercise and 8 times in the next 24 h; CGM readings were collected every 5 min in the 24 h before and 36 h after exercise. The primary outcomes was the incidence of hypoglycemia (<70 mg/dl) and hyperglycemia (>200 mg/dl) per 100 patient-hours during and after exercise. Secondary outcomes were the percentage of time in goals (70-200 mg/dl) according to the time before and after exercise and the precision of the data obtained from CGMS during exercise.
Results: Among the 32 patients exercising in the morning, there were 180 events of hypoglycemia detected by CGMS (5.6 per patient) and 39 events detected by SMBG (incidence rate 15.2 per 100 patient-hours). The highest risk of hypoglycemia was between 15 and 24 h post-exercise (ie, between 10 pm and 7 am). Of the 30 patients exercising in the afternoon, 322 events were detected by CGMS (10.7 per patient) and 62 events were detected by SMBG (incidence rate 29.0 per 100 patient-hours), and the highest risk of hypoglycemia was between 15 and 21 hours post-exercise (ie, between 7 am and 2 pm). The rates of hypoglycemia following morning and afternoon exercise were significantly different (incidence rate ratio: 0.52, 95% CI (0.43-0.63) P <0.001), but there was no between-groups difference in the risk of hyperglycemia. On the day after exercise, subjects who exercised in the morning spent 20% more time with CGM readings between 70 and 200 mg/dl (p=0.003); there was no such benefit in the afternoon exercise group, but there was an increase in percent of time with CGM readings <70 mg/dl (p=0.011). The accuracy of the data of the CGMS was evaluated by the mean absolute difference between CGM and capillary blood measurements; this was found to be 18.5% and was not affected by exercise.
Conclusions: In type 1 diabetes, exercising in the morning carries a lower risk of subsequent hypoglycemia than does equivalent afternoon exercise. The highest risk of post-exercise hypoglycaemia is between 15 and 24 hours after cessation of exercise. Morning exercise improves metabolic control on day after exercising. The use of continuous glucose monitoring during and after exercise detects a higher number of glycemic excursions than does capillary glucose measurement. CGM precision is not influenced by physical exercise.

Examination of timing of pre-exercise administration of low GI carbohydrates on blood glucose after running in type 1 diabetes mellitus

D.J. West, R.D. Morton, R. Davies, J.W. Stephens, S. Bain, R.M. Bracken;
Sports and Exercise Science Research Centre, Swansea University, United Kingdom.

Background and aims: Current research recommends the use of high GI CHO immediately prior to exercise to prevent hypoglycaemia. In contrast, research examining the use of low GI (LGI) carbohydrates 2 hours before exercise demonstrates more stable blood glucose concentrations after exercise. However, given the slower digestion rates of LGI carbohydrates it is unclear if the timing of consumption of LGI carbohydrates before exercise should differ from those carbohydrates with a HGI. This study examined the blood glucose and metabolic responses to alterations in the timing of isomaltulose, a LGI carbohydrate (GI=32), before running in type 1 diabetes individuals (T1DM).
Materials and methods: Seven T1DM (31±2 years; BMI 26±0.3 kg/m^2; HbA_{1c} 8.3±0.1%) attended the laboratory on four occasions, each time consuming 75 g of isomaltulose and administering a 75% reduced insulin dose, in a randomised fashion. T1DM then remained at rest for 120 (120min), 90 (90min), 60 (60min) or 30 (30min) min before completing 45 min of running at 71±1%VO_{2peak}. Blood glucose concentrations (BG) were measured before and 3 hours after exercise. Substrate oxidation was calculated from respiratory data taken at rest and during exercise. Data (mean±SEM) were analysed using repeated measures ANOVA and expressed as changes from rest.
Results: Fasting BG was similar between conditions. Immediate pre-exercise BG under 30min (+2.8±0.2 mmol.l^{-1}) tended to be lower than 60min (+3.9±0.2 mmol.l^{-1}), 90min (+4.3±0.2 mmol.l^{-1}) and 120min (+4.1±0.6 mmol.l^{-1}), (P<0.1). BG dropped less with exercise under 30min compared to 120min (30min 4.6±0.3 vs. 120min 6.4±0.3 mmol.l^{-1}, P<0.05). In the 60 min post-exercise period BG_{auc} was different under 30min when compared to 60min and 120min (30min 7.8±0.5 *vs.* 60min 10.1±0.7, 120min 5.9±0.5 mmol.l^{-1}.hr^{-1}, P<0.05). The greatest incidence of hypoglycaemia (BG ≤3.5 mmol.l^{-1}) occurred under 120min from 60 min onwards following exercise (120min, n=5; 90min, n=2; 60min, n=1 and 30min n=0). Substrate oxidation rates during exercise displayed a strong tendency for greater lipid (30min 0.13±0.01 vs. 120min 0.07±0.01 g.min^{-1}) and lower CHO oxidation (30min 3.88±0.08 vs. 120min 4.38±0.05 g.min^{-1}) rates under 30min compared with 120min (P<0.10).
Conclusion: BG concentrations are best preserved after consumption of the low GI carbohydrate isomaltulose 30 minutes before exercise. Better preservation of post-exercise glycaemia in the 30 min ingestion trial led to a shorter digestion time before and during exercise, altering fuel metabolism towards lipid combustion and reducing the incidence of post-exercise low blood glucose.

Heat flux is inversely associated with glucose concentrations in free living subjects with type 1 diabetes

J.J. Valletta[1,2], A.J. Chipperfield[2], G.F. Clough[1], C.D. Byrne[1];
[1]Institute of Developmental Sciences, Endocrinology and Metabolism Unit, [2]Computational Engineering and Design Group, School of Engineering Sciences, University of Southampton, United Kingdom.

Background and aims: Good glycaemic control in people with type 1 diabetes is achieved by the right balance of calorie intake, exogenous insulin administration and physical activity energy expenditure (PAEE). Few trials have studied the continuous relationship between PAEE and glucose concentrations in free-living individuals during normal daily living. Most studies to date have studied fit adults in a controlled environment while following an exercise protocol. The aim of our study was to investigate the relationship between a continuous read out of glucose concentrations and daily physical activity energy expenditure in a free-living environment.
Patients and methods: 15 adults (9 female) with type 1 diabetes have been studied (age=37±10y, BMI=26.1±6kg.m^{-2}, diabetes duration=17±11y, HbA_{1c}=8.2±1.3%, mean±SD). Participants with clinical evidence of diabetic neuropathy were excluded. The participants wore a SenseWear Pro2 armband (BodyMedia Inc., USA) and a Guardian Real-Time Continuous Glucose Monitoring System (CGMS) (Medtronic MiniMed Inc., USA) continuously for up to 15 days. The armband is worn on the right triceps muscle and is only removed prior to water-based activities. The SenseWear Pro2 utilises five sensors (two accelerometers, heat flux, galvanic skin response, skin and near-body temperature sensors) to provide an estimate of overall physical activity energy expenditure. The Guardian CGMS monitors interstitial glucose concentrations from which a blood glucose value is estimated every 5mins using a proprietary algorithm. The participants were asked to perform normal daily activities and not to change their usual behaviour.
Results: Both devices were worn for 9±3days (mean±SD) and a total of 139 days of data were analysed. There was no association between mean daily PAEE, measured as area under curve for metabolic equivalent (AUC_{METs}) and mean daily glucose concentrations, measured as area under curve for blood glucose (AUC_{BG}) (r=-0.10, p=0.26), although there was a correlation between the variance in blood glucose and the variance in METs (r=0.26, p=0.002). Interestingly, there was also an association between AUC_{BG} and area under curve for heat flux (AUC_{HF}) (r=-0.26, p=0.002), even though AUC_{METs} and AUC_{HF} are strongly correlated (r=0.40, p<0.0001).
Conclusion: We show for the first time a strong inverse relationship between heat flux and a measure of glycaemic control and a positive relationship between variance in glucose concentrations and variance in physical activity levels in free living people. The data shows that greater fluctuations in physical activity are associated with greater variation in blood glucose levels throughout the day. Since heat energy (measured as heat flux) is a by-product of ATP generation in mitochondria, these data suggest that higher levels of mitochondrial activity are related to lower levels of glucose concentrations. We suggest that further work is needed to explore the relationship between ATP generation and glycaemic control and to determine whether heat flux could potentially be used as a novel non-invasive measure of glycaemic variability.

Glucose regulation of STIM1 translocation reflecting store-operated channel modulation in pancreatic islet cells

G. Tian[1], A.V. Tepikin[2], A. Tengholm[1], E. Gylfe[1];
[1]Department of Medical Cell Biology, Uppsala University, Sweden, [2]The Physiological Laboratory, University of Liverpool, United Kingdom.

Background and aims: Store-operated calcium channels (SOCs) are proposed important both for the regulation of insulin and glucagon secretion. Recent studies have identified STIM1 as a Ca^{2+} sensor in the ER. This protein oligomerizes upon Ca^{2+} store depletion and translocates to plasma membrane (PM)-adjacent regions of the ER where it interacts with the channel-forming PM molecule Orai1 that participates in the formation of SOCs. The aim of the present study was to clarify the movements of STIM1 in pancreatic islet cells under conditions known to modulate insulin and glucagon secretion.
Materials and methods: Islets isolated from C57/Bl mice were infected with adenovirus expressing STIM1 protein fused with enhanced yellow fluorescent protein (EYFP). STIM1-EYFP translocation in peripherally located islet cells was studied with confocal and total internal reflection fluorescence (TIRF) microscopy. Glucagon-releasing α- and insulin-secreting β-cells were identified by immunostaining, cell size and their different responses to adrenaline.
Results: In 3 mM glucose there was diffuse STIM1-EYFP fluorescence in peripheral islet cells with confocal microscropy, but some PM-associated fluorescence puncta were observed in TIRF microscopy. Depletion of the ER Ca^{2+} stores by inhibition of the ER Ca^{2+} ATPase with cyclopiazonic acid (CPA), which activates SOCs in α- and β-cells, induced after a delay of 118 ± 21 s pronounced formation of STIM1-EYFP puncta that preferentially associated with the PM. Less pronounced PM translocation was observed after islet exposure to Ca^{2+}-deficient medium containing EGTA. In the presence of 3 mM glucose about 70% of the islet cells reacted to 5 μM adrenaline with a loss of PM-associated STIM1-EYFP fluorescence indicating dissociation from the PM. These cells were larger than other cells and stained for insulin. In about 10% of the cells, that were smaller and stained for glucagon, adrenaline instead triggered pronounced translocation of STIM1-EYFP to the PM with formation of distinct puncta. When the glucose concentration was raised from 3 to 20 mM, there was a 248 ± 32 s delayed reduction of PM-associated STIM1-EYFP fluorescence in β-cells that only partially recovered after reintroduction of 3 mM glucose but the PM STIM1-EYFP fluorescence was rapidly restored in glucose-deficient medium. Stepwise increase of the glucose concentration from 0 to 3, 7, 11 and 20 mM induced graded reduction of PM STIM1-EYFP fluorescence with maximal effects at 3 and 11 mM in adrenaline-identified α- and β-cells, respectively.
Conclusions: The effects of CPA, glucose, and adrenaline on STIM1 localization are consistent with their stimulatory and inhibitory effects on SOCs in α- and β-cells. The glucose sensitivity of STIM1 translocation is considerably higher in α- than in β-cells, consistent with a proposed role of SOC inactivation in glucose inhibition of glucagon secretion.

Glucose inhibits glucagon secretion from mouse pancreatic islets independently from Zn^{2+} or somatostatin, and from an action on K_{ATP} channels

R. Cheng-Xue[1], L. Noel[1], M.A. Ravier[1], F. Chimienti[2], F. Schuit[3], P. Gilon[1];
[1]Université Catholique de Louvain, Brussels, Belgium, [2]Mellitech, Grenoble, France, [3]Katholieke Universiteit Leuven, Belgium.

Background and aims: The mechanisms by which glucose (G) inhibits glucagon secretion are still unknown. The role of K_{ATP} channels in the G-induced suppression of glucagon secretion (GISG) is unclear and has been assessed here using NMRI mice and K_{ATP} channel modulators, or SUR1 knockout mice ($SUR1^{-/-}$), contributed by the Bryan Lab. Several hypotheses suggest that a paracrine factor, i.e. zinc released from β-cells or somatostatin released from δ-cells, is responsible for GISG. Zinc is specifically accumulated within granules of insulin by the ZnT8 transporter since no zinc exocytosis is observed in ZnT8 KO mice. In the present study, we have evaluated the role of zinc and somatostatin in GISG by using ZnT8 KO ($ZnT8^{-/-}$) and C57BL/6J mice ($ZnT8^{+/+}$, used as control), and somatostatin KO ($SST^{-/-}$) and CBA/Ca x C57BL/10 F1 mice ($SST^{+/+}$, used as control).
Materials and methods: Mouse islets were isolated by collagenase digestion of the pancreas and cultured overnight in RPMI 1640 medium containing 7 mM G. Glucagon secretion from islets was measured either in perifusion experiments in the continuous presence of a 6 mM mixture of amino-acids (2 mM alanine, 2 mM glutamine, 2 mM arginine) or in incubation experiments (only for the experiments with $ZnT8^{-/-}$ and $ZnT8^{+/+}$ islets) in the continuous presence of 20 mM arginine.
Results: Increasing the [G] of the perifusion medium from 1 to 7 mM reversibly inhibited glucagon secretion from NMRI islets. Addition of 500 μM of the K_{ATP} channel closer, tolbutamide, to a medium containing 1 mM G did not reproduce the inhibitory effect of 7 mM G, whereas the K_{ATP} channel opener diazoxide (250 μM) strongly inhibited glucagon secretion. These effects of tolbutamide or diazoxide were specific for K_{ATP} channels since they were not observed with $SUR1^{-/-}$ islets. Increasing the [G] of the perifusion medium from 1 to 7 mM in the continuous presence of 500 μM tolbutamide inhibited glucagon secretion from NMRI islets, but to a much lesser extent than in the absence of the sulfonylurea. 7 mM G also decreased glucagon secretion from $SUR1^{-/-}$ islets, but again to a lesser extent than from WT islets. In the continuous presence of 250 μM diazoxide, increasing [G] from 1 to 7 mM reversibly suppressed the already low glucagon secretion. Perifusion experiments performed with $SST^{+/+}$ and $SST^{-/-}$ islets showed that glucagon secretion elicited by 1 mM G was higher with $SST^{-/-}$ than $SST^{+/+}$ islets, and that G inhibited glucagon secretion of both types of islets. Incubation experiments performed with $ZnT8^{-/-}$ and $ZnT8^{+/+}$ islets demonstrated that G decreased glucagon secretion to the same extent in both types of islets.
Conclusion: The observations that tolbutamide did not reproduce the inhibitory effect of G, and that G could inhibit glucagon secretion in the presence of tolbutamide or diazoxide and in $SUR1^{-/-}$ islets suggest that G can modulate glucagon secretion independently from K_{ATP} channels. However, an involvement of these channels cannot entirely be ruled out because GISG was blunted by tolbutamide or in $SUR1^{-/-}$ mice. Somatostatin exerts a tonic inhibitory effect on glucagon secretion. However, neither somatostatin nor zinc are the paracrine factor responsible for GISG.

Glucagon normalises disposition index by increasing acute insulin response to intravenous glucose: comparison with incretins

G. Pacini[1], B. Ahrén[2];
[1]Metabolic Unit, ISIB-CNR, Padova, Italy, [2]Department of Medicine, Lund University, Sweden.

Background and aims: Besides insulin resistance and defective insulin secretion, impaired glucose tolerance and type 2 diabetes are also associated with hyperglucagonemia due to inadequate suppression of glucagon production. While it is known that insulin resistance is compensated by increased insulin secretion to maintain normoglycemia, the consequence of the hyperglucagonemia as an adaptive response is not known. The model of glucose intolerance in mice given high-fat feeding is associated with markedly reduced glucose elimination after intravenous glucose, because of insufficient hyperinsulinemia. We examined whether the defective adaptations can be normalized by glucagon, as previously was documented for the incretins GIP and GLP-1.
Materials and methods: C57BL/6J mice were fed a normal chow (ND, 11%) or a diet with 60% fat for 8 weeks (HF). After baseline blood sample, a bolus injection of 35 g/kg glucose with or without addition of synthetic GIP or GLP-1 (at 3 nmol/kg) and glucagon (at 1 and 10 μg/kg) was given intravenously followed by six blood samples in 50 min with glucose and insulin measurements. The insulin sensitivity index (S_I) was estimated with the minimal model. Insulin secretion (early phase) was assessed as the increase in insulin levels within 5 min after injection (dAIR); glucose elimination (K_G) was the percent reduction of log-transformed glucose during the first 20 min; B-cell adaptation was calculated as $S_I \times$dAIR (disposition index, DI) and total B-cell sensitivity as the ratio of the area under the curve of insulin to that of glucose.
Results: Metabolic parameters are shown in Table 1. K_G was lower in HF fed mice ($P<0.0002$), normalized with incretins, but even worsened with glucagon ($P=0.008$). S_I was reduced in HF ($P<0.00001$) but neither incretins nor glucagon were able to restore a normal sensitivity. On the other hand, both incretins and glucagon yielded a marked increase of the first phase response (dAIR, $P<0.00001$): higher with glucagon, as also reflected by an elevated to-

tal B-cell sensitivity *vs.* HF and HF+incretins (P<0.02). The resulting DI was completely normalized as it was with incretins.
Conclusion: Glucagon, as the incretins, acts on the adaptive mechanisms of the B-cell by eliciting an upregulation of the response to the glucose stimulus, thus restoring a normal disposition index. This is seen in spite of being unable, as the incretins, to ameliorate insulin sensitivity in severe HF induced insulin resistant mice.

Table 1. Metabolic Parameters (means±SE)

	ND (n=89)	HF (46)	HF+incretins (28)	HF+glucagon (13)

Preserved ability to slow gastric emptying in response to increasing concentrations of orally ingested glucose solutions in patients with type 2 diabetes

T. Vilsbøll[1], J.I. Bagger[1], A. Lund[1], J.J. Holst[2], F.K. Knop[1];
[1]Diabetes Research Division, Department of Internal Medicine F, Gentofte Hospital, Copenhagen, [2]Department of Biomedical Sciences, The Panum Institute, Copenhagen, Denmark.

Background and aims: The rate of gastric emptying (GE) of carbohydrate is a major determinant for postprandial plasma glucose (PG) excursions. It is well established that GE during OGTTs in healthy subjects decreases the greater the glucose amount applied. This mechanism contributes to keep postprandial PG concentrations within a narrow range averting hyperglycaemia. It is unknown whether patients with type 2 diabetes mellitus (T2DM) are able to reduce their GE rate in response to increasing orally administered glucose loads. Therefore, we aimed to investigate the GE rates in patients with T2DM ingesting 'isovolumic' glucose solutions of increasing concentrations.
Materials and methods: GE rate was measured during three 4-hour OGTTs with increasing glucose loads (25 g, 75 g and 125 g) using the paracetamol method in 8 patients with T2DM (fasting plasma glucose (FPG): 7.7 (7.0-8.9) mmol/l (mean (range)); Haemoglobin A_1c (HbA_1c): 7.0 (6.2-8.4)%) and in 8 healthy control subjects (CTRLs) matched for sex, age and BMI (FPG: 5.3 (4.8-5.7) mmol/l; HbA_1c: 5.4 (5.0-5.7)%).
Results: PG peak concentrations increased significantly among patients with T2DM with increasing glucose loads (12.8±0.5, 17.5±0.8 and 17.7±1.2 mmol/l; *p*=0.001) whereas they remained constant in CTRLs (8.9±0.5, 10.4±0.9 and 10.2±0.9 mmol/l; *p*=NS). Interestingly, equal slowing (*p*<0.05) of GE rate (as assessed by time-to-peak of plasma paracetamol) in response to increasing oral glucose loads occurred in both groups (25 g: 41±4 (T2DM) *vs.* 36±5 min (CTRL), *p*=NS; 75 g: 92±9 *vs.* 105±15 min, *p*=NS; 125 g: 131±11 *vs.* 150±16 min, *p*=NS) (Figure 1).
Conclusion: Reduced slowing of GE rate in response to increased orally ingested glucose loads does *not* seem to be a determinant for the inability of patients with T2DM to keep peak PG concentrations constant independently of the amount of glucose ingested.

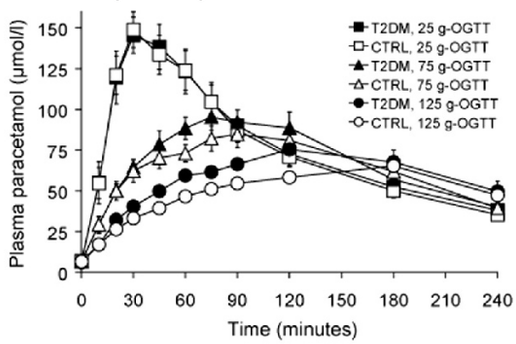

Figure 1. Plasma paracetamol concentrations during 25 g, 75 g and 125 g- OGTTs in patients with type 2 diabetes mellitus (T2DM) and healthy control subjects (CTRL).

Akt influences glycogen synthase in skeletal muscle through regulation of NH_2-terminal phosphorylation

M. Friedrichsen[1,2], J.F.P. Wojtaszewski[3], E.A. Richter[3], R. Ribel-Madsen[1], B.F. Hansen[4], H. Beck-Nielsen[5], A.A. Vaag[1,6], P. Poulsen[1,7];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Department of Biomedical Sciences, University of Copenhagen, Denmark, [3]Molecular Physiology Group, Department of Exercise and Sport Sciences, University of Copenhagen, Denmark, [4]Novo Nordisk A/S, Måløv, Denmark, [5]Diabetes Research Center, Odense University Hospital, Denmark, [6]Department of Clinical Sciences, Lund University, University Hospital MAS, Malmö, Sweden, [7]Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Type 2 diabetes is characterized by reduced non-oxidative glucose metabolism. Although studies have investigated the regulation of the key enzyme in this process, glycogen synthase (GS), the nature of the link between proximal insulin signaling and GS activation is still debated. We previously demonstrated that phosphorylation of residue threonine-308 of Akt (Akt-308phos) and Akt2 activity as well as GS activity in muscle were associated with insulin sensitivity in the present study population. Now, we aimed to evaluate the significance of each step in proximal insulin signaling on GS activity.
Materials and methods: 184 non-diabetic twins were examined with gold-standard techniques including the euglycemic-hyperinsulinemic clamp. Insulin signaling was evaluated at the levels of the insulin receptor, IRS-1-associated phosphoinositide 3-kinase (PI3K), Akt and GS employing kinase assays and phospho-specific Western blotting. Multivariate analyses adjusted for age, sex, VO_{2max}, total fat percentage and basal glycogen content were performed to evaluate the regulation of GS activity/phosphorylation status. A similar model was employed to evaluate the differences among groups in Figure 1.
Results: We demonstrated that the insulin-mediated increase (delta) of GS fractional activity was positively associated with Akt-308phos (*P*=0.002, Figure 1A) and Akt2 activity (*P*=0.008) but not Akt-473phos or insulin receptor tyrosine kinase or IRS-1-associated PI3K activity. Furthermore, Akt-308phos and Akt2 activity were negatively associated with phosphorylation of sites 2+2a (*P*<0.001 and *P*=0.001, respectively, Figure 1B) on GS which in turn was negatively associated with delta GS fractional activity (*P*=0.002, Figure 1D). We found no association between Akt and GS phosphorylation of sites 3a+3b (Figure 1C) which in turn was also not associated with delta GS fractional activity (Figure 1E).
Conclusion: Our study suggests that the association between proximal insulin signaling and GS activity in skeletal muscle primarily is mediated through Akt-dependent regulation of sites 2+2a phosphorylation of GS.

Figure 1. Delta GS fractional activity **(A)**, pGS2+2a **(B)** and pGS3a+3b **(C)** in the lowest (open bars), middle (stripped bars) and highest (black bars) tertiles of Akt-308phos and delta GS fractional activity in the lowest (open bars), middle (stripped bars) and highest (black bars) tertiles of pGS2+2a **(D)** and pGS3a+3b **(E)**. Coordinated myocyte expression of PPARdelta and adiponectin receptors reflects lipid metabolism, but not insulin sensitivity, of the myocyte donors

H. Staiger, F. Machicao, H.-U. Häring;
Internal Medicine IV, Medical Clinic, Eberhard-Karls-University Tübingen, Germany.

Background and aims: Muscle lipid oxidation can be stimulated via peroxisome proliferator-activated receptor (PPAR) delta or adiponectin receptors. Both kinds of receptors sense different signals from adipose tissue: PPARdelta senses insulin resistance-associated long-chain fatty acids, adiponectin receptors the insulin sensitivity-associated adipokine adiponectin. Therefore, we asked whether myocyte expression of PPARdelta and the adiponectin receptors AdipoR1, AdipoR2, and T-cadherin reflects these different insulin sensitivity states.
Materials and methods: Skeletal myoblasts from 39 non-diabetic human donors with a broad range of insulin sensitivity were differentiated into myotubes. mRNA and 28S-rRNA contents were quantified by qPCR. Blood glucose, insulin, free fatty acids, and triglycerides were measured using standard laboratory methods. Insulin sensitivity was calculated from hyperinsulinemic-euglycemic clamp.
Results: Myocyte mRNA contents of PPARdelta, AdipoR1, AdipoR2, and T-cadherin markedly varied between the individual donors, but were not associated with the donors' insulin sensitivity (adjusted for sex, age, and BMI; all $p>0.5$). Unexpectedly, the expression levels of the four receptors were closely interrelated (all $r>=0.75$, $p<0.0001$). Furthermore, PPARdelta was, independently of the other genes, a significant determinant of T-cadherin ($p=0.0002$), but not of AdipoR1 or AdipoR2 (both $p>0.05$), suggesting T-cadherin as a PPARdelta target gene. However, GW501516 treatment did not increase T-cadherin expression ($p=0.8$, $n=16$). After adjustment for sex, age, and BMI, fasting plasma triglycerides were inversely associated with myocyte AdipoR1 and T-cadherin expression (both $p<0.03$) and tended to inversely associate with AdipopR2 and PPARdelta expression (both $p<=0.1$).
Conclusion: Human myocyte expression of PPARdelta or the adiponectin receptors AdipoR1, AdipoR2, and T-cadherin does not reflect the donors' insulin sensitivity. This lack of association might be due to these receptors' coordinated expression. Even though the physiological meaning of this integration of different pathways is currently unclear, the inverse association between myocyte receptor contents and the donors' plasma triglyceride concentrations point to its relevance for human lipid metabolism.

698

TGF beta impairs muscle differentiation and induces autophagy by PED/PEA-15-mediated pathway

S. Iovino, F. Oriente, G. Botta, S. Cabaro, C. Miele, G. Portella, F. Beguinot, P. Formisano;
Cellular and Molecular Biology and Pathology, University of Napoli "Federico II", Napoli, Italy.

Background and aims: Loss of muscle mass and de-differentiation occur in a variety of disease, including cancer, chronic heart failure, acquired immunodeficiency syndrome and diabetes. Preventing muscle wasting by promoting growth and differentiation has been proposed as a possible therapeutic approach. Tgf beta is an important negative modulator of myogenesis. However, its role in adulthood is not fully understood. Recently, it has been shown that TGF beta activates autophagy, which plays a critical role in protein breakdown, muscle atrophy and myofiber survival. Although autophagy has been found impaired in atrophying muscle, the exact mechanisms by which its deregulation might impair skeletal muscle differentiation are still unclear.
Results: Western blot and qRT-PCR analysis revealed that in L6 skeletal muscle cells, TGF beta1 stimulation increased the expression of PED/PEA-15, a gene overexpressed in type 2 diabetic patients. Moreover, Tgfbeta1 led to LC3 I/II conversion, increased expression of beclin-1 and enhanced the formation of autophagosomes in L6 cells, peculiar features of autophagy activation. These molecular events paralleled an impairment of L6 myotubes differentiation, as revealed by morphological analysis and reduction of myoD1, myogenin and glut4 gene expression. Importantly, silencing of PED/PEA-15 by specific shRNA restored the expression of myoD1, myogenin, and glut4 and L6 differentiation upon TGF beta1 stimulation. Interestingly, silencing of PED/PEA-15 also partially reverted the LC3 I/II conversion, beclin-1 levels and autophagosome formation. Furthermore, FACS analysis showed that the transfection of PED/PEA-15 cDNA in L6 cells, which we have previously described to induce insulin-resistance, activated autophagy and impaired the myotubes formation. The block of autophagy in L6PED by using 3-Methyladenine, restored myotubes formation and recovered the expression of differentiation markers. These data indicate that Tgf beta may impair skeletal muscle differentiation by inducing autophagic process and PED/PEA-15 might be a key regulator to mediate this effect.
Conclusion: These results suggest the existence of a direct relationship between insulin-resistance, autophagy and muscle de-differentiation.

699

Cyclin G2: a downstream cellular marker for the mitogenicity of insulin, insulin-like growth factors and insulin analogues?

P. De Meyts[1], A.M. Svendsen[1], C.B. Warzecha[1], W. Sajid[1], J. Hald[2], J. Nøhr[1];
[1]Receptor Systems Biology Laboratory, [2]Dept of Beta Cell Regeneration, Hagedorn Research Institute, Gentofte, Denmark.

Background and aims: The cellular and molecular mechanisms whereby some insulin analogues may cause enhanced stimulation of cell proliferation through either the insulin receptor (IR) or the IGF-I receptor (IGF-IR) are incompletely understood. Previous research in our laboratory has demonstrated differential metabolic and mitogenic signalling with some ligands in L6 rat myoblasts overexpressing the human IR (L6-hIR). While insulin was very potent in stimulating thymidine incorporation, the insulin mimetic peptide S597 had a poor mitogenic response and unlike insulin, caused a poor stimulation of the ERK/MAPK pathway. Gene expression profiling showed that the gene most downregulated (30-fold) by insulin (but 10 times less by S597)

was *ccng2*, the gene coding for cyclin G2, an atypical cyclin downstream of FOXO1 that blocks the cell cycle at the G1/S transition. Our hypothesis is that cyclin G2 may be a key downstream effector of the mitogenicity of insulin and IGFs, and therefore may be a useful cellular biomarker of mitogenicity.
Materials and methods: L6 myoblasts (WT and h-IR), were stimulated with insulin, Asp B10-insulin (X10), or insulin-like growth factor-I (IGF-I), in the absence or presence of the PI3-K inhibitors Wortmannin and LY294002 and the MAPK inhibitors PD98059 or UO126. Clinically relevant analogues were also tested. The human beta cell line INS-1 was stimulated with insulin, X10, IGF-I and GLP-1. The cells were lysed using TRI® Reagent and RNA was extracted. Gene expression was measured in a two-step qRT-PCR. The C_t values were normalized to 18S RNA and fold changes were calculated.
Results: In wild type L6 cells, expressing no IRs and 135.000 IGF-IRs, insulin was less potent than IGF-I in downregulating *ccng2* (3-fold vs 10-fold at 10 nM). Glargine, glulisine and aspart insulins had effects comparable to insulin while detemir had no significant effect on *ccng2.* In L6-hIR cells, expressing 275.000 IRs and 230.000 IGF-IRs (or hybrids), insulin, IGF-I and X10 insulin were all very potent downregulators of *ccng2*. IGF-I had the highest response, downregulating the expression of *ccng2* 50-fold after 3 hours of stimulation with 10 nM. Both insulin and X10 insulin downregulated gene expression 25-fold after 3 and 8 hours respectively. Inhibitors showed that both the MAPK and PI3-K pathways are involved in the regulation of *ccng2*. A 2 to 3-fold downregulation of *ccng2* was seen in INS-1 cells with insulin, X10 and IGF-I, as well as with GLP-1, all at 10nM.
Conclusion: X10 and IGF-I, both having a higher mitogenic potency than insulin, have a higher effect on the expression of the cell cycle inhibitor *ccng2* than insulin has, making this gene a possible candidate as a cellular biomarker for mitogenicity.

Essential but not diabetogenic fatty acids of skeletal muscle structural and neutral lipids are associated
S.B. Haugaard[1,2], S. Madsbad[3], H. Mu[4], A.A. Vaag[5];
[1]Clinical Research Centre, University Hospital of Copenhagen, Hvidovre, [2]Dept. of Internal Medicine, University Hospital of Copenhagen, Amager, [3]Dept. of Endocrinology, University Hospital of Copenhagen, Hvidovre, [4]Dept. of Pharmaceutics and Analytical Chemistry, Faculty of Pharmaceutical Sciences, University of Copenhagen, [5]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Fatty acid (FA) composition of structural membrane phospholipids may reflect dietary FA sources in man. However, it is unknown the extent to which skeletal muscle phospholipid FA composition reflects and/or is associated with intramyocellular triglyceride FA composition. In particular, the association between structural and intramyocellular lipids for essential FA of marine origin facilitating insulin action and the saturated FA palmitic acid, respectively, is of interest to study due to their different effects on health including insulin action.
Materials and methods: Vastus lateralis skeletal muscle biopsies were obtained from 59 weight-stable sedentary subjects, i.e. 27 obese women (7 diabetic), 20 obese men (6 diabetic), and 12 lean healthy normal-weight subjects (7 women). FA composition of neutral and structural fat was determined by thin-layer and gas-liquid chromatography.
Results: In structural versus intramyocellular lipids, the concentration of essential FA of dietary origin including linoleic (C18:2n-6) and linolenic (C18:3n-3) FA correlated significantly (r=0.34, P<0.01; r=0.62, P<0.001). Similarly, the concentration of polyunsaturated FA of marine origin (r=0.51, P<0.001) including the ratio of n-3/n-6 (r=0.56, p<0.001) polyunsaturated FA was also significantly correlated between structural and intramyocellular lipids. The correlations remained virtually unaffected after correction for gender, percentage of body fat mass and insulin resistance (partial correlations, r=0.32; r=0.66; r=0.51; r=0.56, respectively). Total monounsaturated FA (r=0.43, P<0.001; r=0.36, P<0.01)) and trans FA (r=0.33, P=0.01; r=0.32, P<0.02) correlated between the two types of lipids using both univariate as well as corrected analyses. In contrast, total saturated fat (r=0.01, P=ns), including the potentially "diabetogenic" palmitic acid (C16:0, r=0.10, P=ns), did not correlate between structural and intramyocellular FA composition.
Conclusion: Dietary essential FA ingestion may influence the intramyocellular lipid composition. However, the levels of saturated FA including palmitic acid may differ substantially between structural phospholipids versus intramyocellular lipids. Understanding the underlying differential mechanisms regulating structural versus intramyocellular fat metabolism may have implications for health including insulin action.

Suppression of the 5´nucleotidase NT5C2 promotes AMPK phosphorylation and lipid oxidation in human skeletal muscle
S.S. Kulkarni, H.K.R. Karlsson, A. Krook, J.R. Zierath;
Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden.

Objective: The 5'Nucleotidases (NT5) family of enzymes dephosphorylate non-cyclic nucleoside monophosphates to produce nucleosides and inorganic phosphates. We hypothesized that gene silencing of 5'Nucleotidases to increase the intracellular availability of AMP would increase AMPK activity and metabolism.
Research design and methods: The present study was designed to determine the role of the cytosolic 5' nucleotidases in the metabolic responses liked to the development of insulin resistance in obesity and type 2 diabetes.
Results: mRNA expression of NT5C1A and NT5C2 were elevated in extensor digitorum longus (EDL) and soleus muscle of *ob/ob* mice compared to wild-type litter mates, respectively. NT5C1A mRNA was increased in vastus lateralis skeletal muscle obtained from type 2 diabetic patients, compared to normal glucose tolerant subjects. Using siRNA to silence NT5C2 expression in cultured human myotubes, we observed a 2-fold increase in AMPK phosphorylation (Thr^{172}) and a 4-fold increase in phosphorylation of its downstream target ACC (Ser^{79}) (p<0.05). siRNA silencing of NT5C2 expression increased palmitate oxidation 2-fold in the absence and 8-fold in the presence of AICAR. This response was paralleled by an increase in glucose transport

and a decrease in glucose oxidation and incorporation into glycogen and lactate release from NT5C2 depleted myotubes.
Conclusion: Our results provide evidence to suggest that endogenous NT5C2 inhibits basal lipid oxidation and glucose transport in skeletal muscle. Reduction of 5'Nucleotidase expression or activity may be one potential avenue to promote metabolic flexibility in type 2 diabetes.

Bombesin receptor subtype-3 signalling and its role on glucose transport in human myocytes
N. Gonzalez[1], I. Ramos-Álvarez[1], A. Martín-Duce[2], P. Moreno[1], B. Nuche-Berenguer[1], R. Sanz[1], S. Portal-Nuñez[1], R.T. Jensen[3], M.L. Villanueva-Peñacarrillo[1];
[1]IIS-Fundación Jiménez Díaz, Madrid, Spain, [2]Universidad de Alcalá de Henares, Madrid, Spain, [3]National Institutes of Health, Bethesda, USA.

Background and aims: Bombesin Receptor Subtype-3 (BRS-3) is one of the candidate genes of obesity; in fact, BRS-3-knock-out mice is characterized by hypertension, insulin resistance, mild obesity, impaired GLUT-4 translocation in adipocytes and unbalanced glucose metabolism, suggesting a role of BRS-3 in glucose homeostasis. Previously, it was shown not only that human skeletal muscle expresses functional BRS-3, but also a lower than normal levels of its gene expression in muscle tissue from Type-1, Type-2 and obese patients. The aim of this study was to gain insight into the BRS-3 signalling pathways in normal human myocytes, by using the BRS-3 agonist peptide [D-Tyr(6),βAla(11),Phe(13),Nle(14)]Bn-(6-14)] (BRS-3-AP), and to explore the action of BRS-3-AP upon glucose transport (GT).
Materials and methods: Primary culture myocytes were established from skeletal muscle pieces (≈400 mg), obtained, previous informed consent given, from five normal subjects (5F; age: 49±9 yr; fasting plasma glucose: 96±6 mg/dl) undergoing surgery. PKB and p42/44 MAPKs activity - phosphorylation degree- was measured by immunoblotting, in cells after 3 min incubation in the absence (control) and presence of BRS-3-AP (10^{-10}-10^{-8} M); GT was examined as ^{3}H-2-deoxy-D-glucose incorporation, in the absence and presence BRS-3-AP (10^{-12}-10^{-7} M) and without and with 10^{-6} M wortmannin or $2.5x10^{-5}$ M PD-98059, respective inhibitors of PI3K/PKB and MAPKs activity; insulin was also included in all assays as positive control.
Results: BRS-3-AP, at 10^{-9} M and 10^{-8} M, clearly increased (p<0.05) PKB phosphorylation (168±17% control and 192±42% control, respectively) to the same level as that reached by 10^{-9} M insulin (175±28%, p<0.05); however, while at 10^{-10} M and 10^{-9} M BRS-3-AP failed to modify the global MAP kinases activity (overall mean value: 101±7% control), a clear increase (p<0.05) in the phosphorylation level of p42/44 MAPKs occurred when 10^{-8} M BRS-3-AP was present (p-p42: 160±22% control; p-p44: 142±14%), values of the same of magnitude as those by 10^{-9} M insulin (p-p42: 131±2% control; p-p44: 126±9%). BRS-3-AP caused a concentration-related stimulation of GT, which was already detected at 10^{-10} M of the peptide (133±11% control, p<0.05), maximal at 10^{-9} M (159±13%, p<0.01) and maintained thereafter up to 10^{-7} M BRS-3-AP (10^{-8} M: 158±18% control, p<0.02; 10^{-7} M: 196±36, p<0.05), effect which was similar to that induced by insulin. Wortmannin abolished the stimulatory action of 10^{-8} M BRS-3-AP on GT (102±7% control), and the same blocking effect was observed in the additional presence of PD-98059 (94±4%).
Conclusion: These results implicate human BRS-3 in the glucose homeostasis process, and open the possibility that this receptor could be used as a molecular target, and/or its agonist peptide, in the therapy of diabetes and obesity.

The role of phospholemman in the regulation of glucose uptake in insulin sensitive tissues
B. Benziane, H. Boon, S. Pirkmajer, S. Jagtap, J.R. Zierath, A.V. Chibalin;
Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Phospholemman (PLM, FXYD1) is a phosphoprotein expressed in the cell plasma membrane in different tissues including adipose tissue, liver, heart and skeletal muscle. Phosphorylation of PLM leads to an increase in Na^+/K^+ pump activity and thus regulates active ion transport. In adipocytes PLM is reported to be involved in insulin-induced GLUT4 translocation to the plasma membrane. The aim of this study was to determine the role of PLM in insulin-induced glucose uptake in skeletal muscle and adipocytes.
Materials and methods: L6 myoblasts, which have a intrinsically low PLM expression, were transfected with plasmids encoding either wild-type PLM, phosphorylation-mutant Ser68Ala-PLM or double-mutant Ser63Ala/Ser-68Ala-PLM. Thereafter, insulin-stimulated glucose uptake was measured. Interaction of GLUT4 and PLM was assessed by co-immunoprecipitation. 3T3-L1 fibroblasts were induced to differentiation into adipocytes. In differentiated adipocytes, siRNA PLM silencing was performed and insulin-stimulated glucose uptake was measured.
Results: PLM overexpression increased insulin-stimulated glucose uptake in comparison with mock transfected cells, whereas overexpression of mutant Ser63 and/or Ser68 had no effect on insulin-stimulated glucose uptake. Basal glucose uptake was unaltered by overexpression of PLM. PLM co-immunoprecipitates with GLUT4 in rat epitochlearis muscle and this interaction is increased after insulin stimulation. In 3T3-L1 cells the induction of PLM expression follows GLUT4 expression during differentiation into adipocytes. The silencing of PLM in 3T3-L1 adipocytes leads to decrease in insulin-stimulated glucose uptake.
Conclusion: PLM over-expression enhances insulin-stimulated glucose uptake in L6 myoblasts, and the effect is dependant upon PLM phosphorylation on Ser63 and/or Ser68 residues. Increased co-immunoprecipitation of PLM and GLUT4 after insulin stimulation provides evidence to suggest that an interaction between PLM and GLUT4 may be involved in regulation of the glucose uptake. Furthermore, the expression level and phosphorylation status of PLM appears to be important for the regulation of insulin-stimulated glucose uptake in insulin sensitive tissues.

The beneficial effect of electro-acupuncture on insulin resistance
D. Koya[1], F. Liang[2];
[1]Endocrinology & Metabolism, Kanazawa Medical University, Kahokugun, Ishikawa, Japan, [2]Department of Traditional Chinese Medicine, University of Science and Technology, Wuhan, China.

Background and aims: Electro-acupuncture (EA) improves insulin resistance, although the biochemical mechanism underlying this effect remains unclear. This study investigated the effect of low-frequency EA on metabolic action in genetically insulin-resistant diabetic db/db mice.
Materials and methods: Nine-week-old db/m and db/db mice were randomly divided into four groups: db/m, db/m+EA, db/db, and db/db+EA. Db/m+EA and db/db+EA mice received 3-Hz EA five times/wk for 8 weeks.
Results: The EA reduced fasting blood glucose and maintained insulin levels without significant alteration of food intake or body weight in db/db mice. Improved insulin sensitivity was established in EA-treated db/db mice by intraperitoneal insulin tolerance test. EA also decreased free fatty acid levels in the db/db mice and increased skeletal muscle sirtuin 1 (SIRT1) protein expression. These effects induced concurrent upregulation of the genes related to mitochondrial biogenesis such as peroxisome proliferator-activated receptorγ (PPARγ) coactivator 1alpha (PGC-1alpha) and nuclear respiratory factor 1 (NRF1). Furthermore, EA treatment activated AMP-activated protein kinase (AMPK) and increased Akt phosphorylation in skeletal muscle of the db/db mice.
Conclusion: These findings suggest that EA has a beneficial effect on insulin resistance, at least partly via stimulating SIRT1/PGC-1alpha and AMPK activity, resulting in improved insulin signal defect.

A mRNA marker for glycolytic muscle fibres may be used to determine fibre type composition in human skeletal muscle
A.H. Olsson, T. Elgzyri, E. Laurila, L. Groop, O. Hansson, C. Ling;
Department of Clinical Sciences, Diabetes and Endocrinology, Lund University Diabetes Center, Malmo, Sweden.

Background and aims: Human skeletal muscle contains three major fibre types distinguished by their myosin heavy chain (MHC) isoforms. The mitochondria content and oxidative capacity is the highest in slow oxidative type I fibres, lower in fast oxidative type IIa fibres, and lowest in fast glycolytic type IIx/d fibres. The amount of oxidative type I fibres is reduced and

glycolytic type IIx/d fibres is increased in muscle from patients with type 2 diabetes. We have previously shown that mRNA expression level of markers for oxidative fibres were positively related to insulin-stimulated glucose uptake and VO2max, meanwhile mRNA expression level of markers for glycolytic fibres were negatively related to these metabolic factors. The aim of the present study was to investigate whether mRNA expression levels of fibre type markers can be used as a proxy to determine fibre type composition in human skeletal muscle.
Materials and methods: Human skeletal muscle biopsies were analysed from two different cohorts (cohort 1 n=36 and cohort 2 n=37). An ATPase staining method was used to determine the fibre types. The expression levels of three fibre type markers; *MHC7* (slow oxidative), *MHCIIa* (fast oxidative) and *MHCIIx/d* (fast glycolytic), were measured using microarrays and the mRNA expression was correlated with muscle fibre type.
Results: By using bivariate non-parametric correlation tests, we found that *MHCIIx/d* mRNA expression was positively correlated to the level of type IIx/d muscle fibres in both cohorts (cohort 1: r=0.39 and p=0.020; cohort 2: r=0.59 and p=0.00023), meanwhile mRNA expression of *MHC7* and *MHCIIa* did not significant correlate with levels of its respective fibre type in neither cohort. When using regression analysis corrected for BMI, age and diabetes status, the same results were obtained. *MHCIIx/d* mRNA expression was positively related to type IIx/d fibres in both cohorts (cohort 1: beta = 0.04 ± 0.002 and p=0.016; cohort 2: beta= 7.99 ± 2.92 and p=0.020), meanwhile no significant relationship was found between *MHC7* mRNA expression and amount of type I fibres or between *MHCIIa* mRNA expression and amount of type IIa fibres in neither cohort. Interestingly, mRNA expression of *MHCIIx/d* was negatively correlated to both amount of type I and type IIa fibres in cohort 2 (r= -0.41 and p=0.012, respectively, r= -0.38 and p=0.028).
Conclusion: Fibre type composition has been shown to be of importance in the pathogenesis of type 2 diabetes and a practical marker is needed. Here we show that the mRNA expression level of *MHCIIx/d*, may be used as such a marker for fast glycolytic muscle fibres in human skeletal muscle.

PS 59 Insulin action and metabolism in adipose cells

Microfluidic technology for multi-parametric studies on patient-derived three-dimensional human adipose tissue model
M. Flaibani, A. Zambon, E. Cimetta, E. Magrofuoco, N. Elvassore;
Dep. Chemical Engineering Principle and Practice, University of Padova, Italy.

Background and aims: Type 2 Diabetes Mellitus is a complex disease affecting many pathways in different tissues. The complexity of this disease led to the use of several classes of drugs acting with different mechanisms and targets and with effects which often change between patients. The screening of all these anti-diabetic drugs with animal models is not economically and timing sustainable and often not giving reliable results for human. On the other hand, specific study on human patients are possible but are tremendously expensive and require a huge effort in term of ethical approval and safety issues. Within this scenario we aim at developing a microfluidic platform allowing to perform in vitro highthroughput patient-specific tests of anti-diabetic drugs on patient-derived three-dimensional human adipose tissue. In particular, the first step is the realization of a microfluidic system for culturing human adipose tissue able to control the temporal evolution of culture conditions in terms of concentration of oxygen, metabolites, and insulin and able to perform multi-parametric analyses of the adipose tissue behaviour.
Materials and methods: Biopsies of subcutaneous and visceral adipose tissues were obtained from both patients affected by Type 2 Diabetes and insulin-sensitive individuals. 1cm^3 biopsy was minced right after surgery into 10-20mg tissues. Each piece was placed in a 24well plate with 1ml medium for 24h. Then the tissue was either cultured for additional time in the 24well plate with fresh medium or placed into the microfluidic system. A microfluidic platform including micro-valves, injectors, pumps, mixers was realized by soft-lithographic technique and its design, development, and application was assisted by mathematical modeling. In line measurements of tissue metabolic activity were performed using micro-biosensors placed downstream the culture chambers and able to detect glucose, lactate and oxygen concentration. The tissue responses to insulin were investigated also through analyses of free fatty acids and glycerol. Viability and histological analyses were performed at the end of the cultures.
Results: Microscale adipose tissues were cultured within the microfluidic platform for up to 4 days. MTT assay at the end of the culture showed high tissue viability and no significant differences with controls in 24well plates. On the other end, the microfluidic system allowed a two times higher glucose uptake then the controls by reducing the glucose diffusive resistance. We then investigated the effect of different insulin concentrations (20, 40 and 100nM). Preliminary results obtained with tissues of insulin-sensitive individuals showed an high variability between biopsies and between cultures from the same biopsy. However, we observed an enhancement of glucose uptake for increasing insulin concentration when using 25mM glucose medium. We also investigated the difference on glucose uptake between insulin-sensitive individuals and patients affected by Type 2 Diabetes.
Conclusion: We developed a microfluidic platform for culturing small-scale human adipose tissue and allowing to accurately control the temporal evolution of the culture conditions in terms of concentration of metabolites, oxygen, and insulin concentration. This system with in line biosensors open important perspectives towards the realization of high-throughput dynamic screening of anti-diabetic drugs on human adipose tissue.

Effects of different commercial insulins on adipogenesis and adipocyte metabolism
E. Garcia-Escobar[1], F. Rodriguez-Pacheco[2], S. Garcia-Serrano[1], J.M. Gomez-Zumaquero[1], S. Morcillo[1], E. Rubio-Martin[1], G.M. Martin-Nuñez[1], C. Gutierrez-Repiso[1], J.J. Haro-Mora[1], F. Soriguer[1], G. Rojo-Martinez[1];
[1]Servicio de Endocrinologia y Nutricion. Hospital Civil de Malaga, CIBERDEM CB07/08/0019 of the Instituto de Salud Carlos III, Malaga, [2]Facultad de Medicina, Departamento de Fisiología, Santiago de Compostela, CIBER of the Pathophysiology of Obesity and Nutrition (CB06/03/0018) of the Instituto de Salud Carlos III, Santiago de Compostela, Spain.

Background and aims: Insulin has several roles in metabolism, so the use of exogens insulins could be modifying metabolic process related with adipo-

cyte metabolism that might explain the secondary problems derivated of insulin therapy. We investigate the effects of six different insulins on adipocyte cell differentiation, lipolytic activity, and expression levels of PPARg, SCD-1, HSL, InsR and SREBP-1c .
Materials and methods: 3T3-L1 cells were induced to differentiate with 6 commercial insulins: Glargine, Lispro, Aspart, Detemir, NPH and regular recombinated human insulin (used as control). Cell differentiation, lipolysis and gene expression were measured at day 7 (D7) and at day 10 (D10) after differentiation induction.
Results: The highest values of cell differentiation and lipolisys were found at D10 for all the insulins tested ($p<0.001$). Preadipocyte differentiation was different according to the insulin used at both moments ($p<0.0001$), Detemir insulin being the least adipogenic. PPARg mRNA level variated according to the insulin and it was a good genetic marker of adipogenesis at D7, but at D10 PPARγ gene expression didn't reflect the differences on the cell differentiation between each insulin. Cells treated with Glargine insulin showed lower antilipolytic effects ($p<0.0001$) with the highest level of HSL expression at both days ($p< 0.0001$ at both days). Gene expression of InsR, SREBP-1c and SCD-1 were different regarding to the insulin investigated ($p<0.0001$, $p<0.0001$and $p<0.001$ respectively at D7; and $p<0.001$, $p<0.003$ and $p<0.005$ respectively at D10)
Conclusion: Detemir insulin is less adipogenic than the other insulins tested, while Glargine insulin is the less anti-lipolitic. The modifications made on commercials insulins also affect the adipocyte differentiation, the lipolysis activity, and the expression of different genes which can modify metabolic pathways independent of glucose metabolism.

Orexin A stimulates lipogenesis and adiponectin expression via PPARgamma-dependent mechanism in isolated primary rat and mature 3T3-L1 adipocytes
M. Skrzypski[1,2], T.T. Le[1], P. Kaczmarek[2], P. Pietrzak[3], E. Pruszynska-Oszmalek[2], D. Szczepankiewicz[2], A.M. Arafat[4], B. Wiedenmann[1], K.W. Nowak[2], M.Z. Strowski[1];
[1]Hepatologie, Gastroenterologie & Interdisziplinäres Stoffwechsel-Centrum/Endokrinologie und Diabetes, Charité - Universitätsmedizin Berlin, Germany, [2]Animal Physiology and Biochemistry, Poznan University of Life Sciences, Poland, [3]Department of Physiological Sciences, Faculty of Veterinary Medicine, Warsaw, Poland, [4]Endocrinology, Diabetes, and Nutrition, Charité - Universitätsmedizin Berlin, Germany.

Background and aims: Orexin A (OXA) plays a role in the regulation of food intake and body metabolism. Dysfunction of the orexin system is associated with obesity and glucose intolerance. Recently, orexin receptors were identified in human adipocytes. Activation of orexin receptors in adipocytes increased PPARgamma2 expression and reduced lipolysis. Here, we characterize the effects of OXA on glucose uptake, lipid accumulation, adiponectin gene expression, and secretion in adipocytes. We also describe the underlying mechanism.
Materials and methods: We used isolated primary rat adipocytes and differentiated 3T3-L1 adipocytes. We studied the effects of OXA on lipogenesis, lipolysis, glucose uptake and ATP levels using biochemical assays, Western blots and immunofluorescence. The effects of OXA on adiponectin secretion and expression were measured by RIA and Western blots. Mechanisms of action were studied using siRNA technique and pharmacological inhibitors of crucial signaling pathways.
Results: OXA stimulated active glucose uptake by translocating the glucose transporter type 4 from plasma into the plasma membrane via the PI3kinase-/AKT-pathway. OXA increased cellular ATP content, as well as lipid accumulation. OXA enhanced the lipogenesis and reduced lipolysis. OXA increased adiponectin secretion and expression. OXA increased the expression of PPARgamma. The effects of OXA on lipogenesis and adiponectin secretion were blocked by pharmacological inhibitors of PPARgamma activity and by specific PPARgamma siRNA.
Conclusion: In summary, our study demonstrates that OXA PI3kinase-/AKT-dependently stimulates glucose uptake in adipocytes and that the evolving energy is stored as lipids. OXA increases the expression and secretion of adiponectin, as well as lipogenesis through PPARgamma-dependent mechanism. The effects of OXA on the function of adipocytes may be of clinical relevance in the pathophysiology of obesity and in peripheral insulin resistance, the hallmark of type 2 diabetes mellitus.

Carrier-mediated trans-membrane delivery of PIP_3 overcomes cellular insulin resistance induced by proximal, but not distal signaling defect
A. Rudich[1], I. Kachko-Chernetsky[2], T. Traitel[2], N. Bashan[1], R. Jelinek[3], J. Kost[2];
[1]Department of Clinical Biochemistry, [2]Department of Chemical Engineering, [3]Department of Chemistry, Ben Gurion University of the Negev, Beer-Sheva, Israel.

Background and aims: Using bio-mimetic liposomes we have identified an efficient specific polyethyleneimine (PEI)-based carrier to efficiently deliver phosphoatidylinositol-3,4,5-trisphophate (PIP_3) across the plasma membranes of cultured muscle and fat cells in a manner that can activate insulin signaling (Diabetologia, 51: S276: 687). In the present study, we aimed at obtaining proof-of-concept for the possibility to utilize PIP_3 to overcome some forms of insulin resistance.
Materials and methods: We utilized chronic exposure of L6 muscle cells to high glucose-high insulin to induce an insulin resistance state characterized by early signalling defect, and 3T3-L1 adipocytes treated with nelfinavir as a cellular model for insulin resistance emanating from signalling defect(s) downstream of endogenous PIP_3 generation (Endocrinology 150: 2618, 2009).
Results: 3T3-L1 adipocytes treated for 18h with the HIV protease inhibitor nelfinavir exhibited marked attenuation of insulin-stimulated translocation and plasma membrane fusion of a GFP-GLUT4-myc reporter. PEI-PIP_3 complexes induced in control cells a nearly full response of GLUT4 translocation compared to that observed with insulin. Yet, after pre-incubation with nelfinavir, the response to PEI-PIP_3 was greatly blunted, suggesting that PEI-PIP_3 can not bypass the signaling defect induced by nelfinavir. In contrast, L6 cells exposed for 18h to high (25 mM) glucose high (100nM) insulin exhibited a 2-fold increase in basal Ser473 phosphorylation of Akt, along with 40% diminished insulin-stimulated Akt phosphorylation. In this system, control cells treated with PEI-PIP_3 exhibited 70% of the 10-fold increase in pS-Akt induced by insulin, and after high-glucose - high insulin treatment the response to PEI-PIP_3 was fully intact. Moreover, pS-Akt was higher after high-glucose - high insulin in response to PEI-PIP_3 than in response to insulin.
Conclusion: We show that efficient carrier-mediated delivery of PIP_3 can elicit biologically relevant insulin-like responses in adipocytes and muscle cells. Insulin resistance resulting from signaling defects downstream of endogenous PIP_3 generation can not be bypassed by introducing exogenous PIP_3. However, PEI-PIP_3 retains its ability to elicit insulin signaling events in muscle cells rendered resistant to the effects of the hormone when the signaling defect is upstream of PIP_3 generation, constituting a proof-of-concept for "second messenger therapeutics" for some forms of insulin resistance.

Immunosuppressive agents alter insulin signalling and glucose and lipid metabolism in human subcutaneous adipocytes
M.J. Pereira[1,2], J. Palming[1], M.K. Svensson[3], M. Aureliano[4], E. Carvalho[2], J.W. Eriksson[1,5];
[1]Department of Molecular and Clinical Medicine, The Lundberg Laboratory for Diabetes Research, Göteborg, Sweden, [2]Center for Neuroscience and Cell Biology, University of Coimbra, Portugal, [3]Department of Molecular and Clinical Medicine, Göteborg, Sweden, [4]FCT- CCMAR, University of Algarve, Faro, Portugal, [5]AstraZeneca R & D, Mölndal, Sweden.

Background and aims: The immunosuppressive agents (IAs), Cyclosporine (CsA) and Tacrolimus (FK) can cause new-onset diabetes in transplant recipients (NODAT). This is one of the most serious long-term metabolic complications of solid organ transplantation and it is associated with increased cardiovascular morbidity and mortality. Rapamycin (Rap), another potent IA and potential anti-tumoral agent, inhibits the mammalian target of rapamycin (mTOR). Although mTOR can mediate nutrient-induced insulin resistance by down-regulating insulin receptor substrate proteins, with subsequently reduced AKT phosphorylation, the effects of Rap on glucose metabolism are unclear. The aim of this study was to elucidate direct effects of IAs on insulin signaling, glucose and lipid metabolism in human subcutaneous adipocytes.
Materials and methods: Abdominal subcutaneous adipose tissue was obtained from healthy volunteers (n=22, BMI: 21-36kg/m^2). After adipocyte isolation, cells were incubated in medium containing 4% albumin with or without IAs: CsA (0.001-10 μM); FK (0.001-10 μM) and Rap (0.001-10 μM),

all ranges including therapeutic levels. Following adipocyte incubation with or without IAs, ^{14}C-Glucose uptake was measured (75 minutes incubation, n=7) and western-blot analyses of insulin signaling protein (IRS1/2, PI3K, GLUT4, AKT and insulin-stimulated pSer473AKT and pThr308AKT) were performed (n=13; 15 minutes, 3 and 24 hours incubation). Basal and isoprenaline-stimulated lipolysis rates were measured after adipocyte incubation with IAs for 2 hours (n=15).
Results: Insulin-stimulated glucose uptake was reduced in a dose-dependent manner after incubation with IAs: CsA by 23-28% ($p<0.001$), FK by 23-43% ($p<0.001$) and Rap by 12-42% ($p<0.001$). Treatment with Rap (≥3 h) caused a reduction in IRS2 protein level by 20% ($p<0.01$). FK and Rap caused a decrease in insulin-stimulated phosphorylation of AKT Ser473 ($p<0.05$), but did not change IRS1, PI3K, AKT and GLUT4 protein levels. Exposure of cells to CsA, FK and Rap increased isoprenaline-stimulated lipolysis (1.7, $p<0.01$; 1.5, $p<0.05$ and 1.2 fold, $p<0.05$, respectively) but only Rap induced basal lipolysis (1.4 fold, $p<0.05$).
Conclusion: These results demonstrate that the investigated IAs, CsA, FK as well as the mTOR inhibitor Rap, impair insulin action on glucose uptake in subcutaneous human adipocytes, and this may be mediated via increased lipolysis and altered insulin signaling. These alterations can contribute to the development of NODAT and to dyslipidemia found in post-transplant patients. Moreover, it is suggested that mTOR is an important modulator of insulin-stimulated glucose uptake. Inhibition by Rap may contribute to the development of NODAT in organ transplanted patients, rather than having an insulin-sensitizing effect.

Metabolic endotoxaemia as a mediator of mitochondrial dysfunction in human adipose tissue, alleviated by salicylate
K.C. McGee[1], G. Tripathi[1], S.J. Creely[1], A.L. Harte[1], M. Langowska[1], N.F. Da Silva[2], A. Brown[2], J. Oscarsson[2], J. Clapham[2], S. Kumar[1], P.G. McTernan[1];
[1]Unit for Diabetes and Metabolism, University of Warwick Medical School, Coventry, [2]CVGI Bioscience, Astrazeneca R&D, Macclesfield, United Kingdom.

Background and aims: The pathogenesis of obesity and type 2 diabetes (T2DM) mediates mitochondrial dysfunction which, in part, may arise from a chronic low level inflammatory response due to gut derived endotoxaemia. Our previous studies have shown that changes in diabetic status increase circulating endotoxin levels. Furthermore our current studies have shown that serum endotoxin levels correlate positively with BMI ($r=0.281$, $p=0.016$) as well as serum insulin levels ($r=0.34$, $p=0.009$) and HOMA index ($r=0.331$, $p=0.021$) suggesting a positive association between circulating endotoxin levels and insulin resistance. As previous studies in muscle from patients with severe IR have highlighted decreased mitochondrial function, we undertook studies to investigate whether endotoxin may, in part, influence mitochondrial dysfunction in human adipose tissue (AT).
Materials and methods: Abdominal subcutaneous (Abd Sc), omental (Om) (BMI: 20.1-33.9kg/m^2, age: 29-48yr; n=35) and Abd Sc T2DM (BMI: 52.4-67.59kg/m^2; age: 29-44yr; n=7) AT was taken from subjects undergoing elective surgery with ethical approval. Gene expression was assessed by qRT-PCR.
Results: In Abd Sc AT, increasing adiposity significantly reduced FAS ($p<0.05$), COX4 and UCP2 mRNA ($p<0.001$), whilst PGC1α mRNA was increased ($p<0.01$). No significant difference in expression was observed in Abd Sc AT from T2DM subjects vs. Abd Sc AT from obese ND subjects. In Om AT, FAS, PGC1α, COX4 and UCP2 mRNA were reduced ($p<0.001$). No significant difference in expression was observed in Abd Sc AT from T2DM subjects vs. Abd Sc AT from obese ND subjects. Therefore we investigated the direct effect of endotoxin (lipopolysaccharide (LPS)) treatment on mitochondrial encoded genes and the therapeutic potential of Salicylate (Sal) in human differentiated adipocytes. Differentiated pre-adipocytes were treated for 24 hr with LPS (100ng/ml) with or without Sal (20mM) and assessed by qRT-PCR. Treatment with LPS+Sal led to a significant up-regulation of NRF1, FAS, UCP2 and UCP3 ($p<0.05$) compared with adipocytes treated with LPS alone.
Conclusion: In summary, these studies highlight significant changes in mitochondrial properties in response to conditions of obesity and T2DM. Such dysregulation in mitochondrial gene expression may, in part, arise due to the effects of inflammation imposed by LPS which appears negated by Sal treatment. Taken together, these data indicate therapeutics to reduce LPS may alleviate mitochondrial dysfunction and its pathogenic consequences.

The effect of ligand activated LXR-alpha on the PPAR-γ-target genes in mature adipocytes
F. Zheng, H. Li, W. Lu, F. Wu, J. Zhou;
Endocrinology, Zhejiang University, Hangzhou, China.

Backgrouds and aims: A selective activation of peroxisome proliferator-activated receptor gamma (PPAR-γ) in adipocytes plays an important role in insulin sensitivity and inflammation. Like PPAR-γ, Liver X receptor alpha (LXR-α), which is another ligand-activated transcription factor in adipocytes, also forms a heterodimer with retinoid X receptor alpha (RXR-α). Whether the activation of LXR-α interferes with the PPAR-γ signaling in adipocytes is unknown. To explore potential interactions between LXR-α and PPAR-γ in adipocytes and investigate the effect of LXR-α activation on the expressions of PPAR-γ target genes.
Methods: Differentiation of pre-adipocytes 3T3-L1 into mature adipocytes were induced by addition of differentiation cocktail for 12 days, and cells were harvested every 2 days for LXR-α mRNA analysis. T0901317 was used to activate LXR-α or Pioglitazone to activate PPAR-γ respectively. Differentiated adipocytes (at day 8) were treated with (1) different concentrations of T0901317 (0, 0.3, 1, 3, 6 and 10uM) for 24 h; (2) different concentrations of T0901317 with 3uM Pioglitazone for 24 h; (3) LXR-α silence (or non-silencing control) for 48 h followed by different concentrations of T0901317 for 24 h; (4) LXR-α silence (or non-silencing control) for 48 h followed by different concentrations of T0901317 with 3uM Pioglitazone for 24 h. Expressions of the PPAR-γ target genes in harvested adipocytes, including adiponectin, resistin and TNF-α, were determined by Real-time_PCR, and Western blot.
Results: (1) LXR-α mRNA level increased dramatically 4 days after the initiation of the differentiation program, reached the peak at day 8 (16.3 times of that in pre-adipocytes 3T3-L1) and gradually declined at day 10 and day 12. (2) Adiponectin, a representative gene product positively regulated by PPAR-γ, was suppressed dose dependently by T0901317 in both the mRNA and the protein levels. mRNA levels of TNF-α and resistin produced by genes negatively regulated by PPAR-γ were increased dose dependently by T0901317. Addition of pioglitazone at a concentration of 3uM partly reversed the expressions of adiponectin, resistin and TNF-α at each concentration of T0901317. However, the dose dependent suppressions of adiponectin and up-regulations of TNF-α and resistin transcriptions by T0901317 were still observed in the presence of pioglitazone. (3) Treated with shRNA specific for LXR-α for 48 h, the differentiated adipocytes were down-regulated by 60-70% in LXR-α protein level. mRNA level of adiponectin was moderately increased, while TNF-α and resistin mRNA levels were decreased by LXR-α silencing at each concentration of T0901317. More significant increase in adiponectin, as well as decrease in TNF-α and resistin mRNA levels were found in presence of 3uM pioglitazone,as compared with those treated with non-silencing control shRNA and different concentrations of T0901317; However, the absolute increase in adiponectin mRNA and reduction in resistin and TNF-α mRNA levels by LXR-α silencing were decreased consistently with the increasing concentration of T0901317, regardless of the presence of 3uM Pioglitazone.
Conclusion: These observations suggest that LXR-α activation interferes with the expressions of PPAR-γ-target genes, indicating a possible role of LXR-α in insulin action by counteracting PPAR-γ signaling in adipocytes.

PPARγ-sparing thiazolidinediones: stimulation of mitochondrial biogenesis by a PGC1α-independent pathway
W.G. McDonald[1], S.L. Cole[1], B.N. Finck[2], D.D. Holewa[1], A.S. Brightwell-Conrad[1], R.R. Eversole[3], J.R. Colca[1], R.F. Kletzien[1];
[1]Metabolic Solutions Development Co, Kalamazoo, [2]Washington University, St. Louis, [3]Western Michigan University, Kalamazoo, USA.

Background and aims: It is well established that mitochondrial content and capacity are decreased in some tissues in insulin-resistant states and type 2 diabetes. Therapeutic agents such as the thiazolidinediones (TZDs) have shown promise in restoring mitochondrial capacity in both experimental models and clinical studies. However, the TZDs have well established side effects which can be traced back to activation of the PPARγ transcription factor. Therefore, we have sought to identify and develop experimental drugs of the TZD class that spare this receptor (PPARγ-sparing thiazolidinediones, PsTZDs) but retain the desirable pharmacology, including stimulation of mitochondrial biogenesis.
Materials and methods: We have used the PsTZD clinical candidate, MSDC-0160, to examine mitochondrial biogenesis in cells derived from brown ad-

ipose tissue (BAT). In this model system, BAT precursor cells are isolated from CD1 mice and maintained in tissue culture.
Results: Treatment of cells with MSDC-0160 elicited the differentiated BAT cellular phenotype after 96 hours of drug treatment. During this timeframe, a robust increase in mitochondrial content was observed as measured by fluorescent dye staining, light microscopy and confirmed by transmission electron microscopy. Expression of the mitochondrial uncoupling protein, UCP1 (mRNA, protein) was first detected following 96 hours of drug treatment and maximum expression was observed after 168 hours. Citrate synthase was monitored as an index of mitochondrial mass and a detailed time course of expression after drug treatment revealed progressive, dose-dependent increases (4 to 5-fold). We assumed that the nuclear transcription factor, PGC1α (peroxisomal proliferator activator receptor γ coactivator 1α), was driving the increased mitochondrial content through expression of nuclear and mitochondrial genes involved in mitochondrial biogenesis. However, analysis of PGC1α mRNA expression as a function of time of drug treatment revealed that there was no detectable increase. We then examined the ability of the PsTZDs to elicit differentiation and mitochondrial biogenesis in BAT precursor cells isolated from mice in which the PGC1α gene had been ablated. We found that cellular differentiation, UCP1 protein expression and mitochondrial biogenesis as measured by citrate synthase activity were robust and similar to that seen in the control animals.
Conclusion: Therefore, we conclude that the PsTZDs are fully capable of stimulating mitochondrial biogenesis through a pathway that does not include PGC1α. This pathway may synergize with the epinephrine/PGC1α pathway. The definition of this PsTZD-stimulated, PGC1α -independent pathway may have important implications for understanding the mechanism of action of insulin sensitizing agents.

PS 60 Glucose and lipid metabolism in animal models

Insights into the mechanism of FATP1 activating effect on pyruvate dehydrogenase

M. Guitart[1], C. García-Martínez[2], A.M. Gómez-Foix[1];
[1]Dep. Bioquímica i Biologia Molecular, CIBERDEM, Universitat de Barcelona, [2]Dep. Patologia i Terapèutica Experimental, CIBERDEM, Universitat de Barcelona, Hospitalet de Llobregat, Spain.

Background and aims: FATP1 is a membrane-bound fatty acid (FA)-binding protein that has acyl-CoA synthetase activity. FATP1 gene expression is highest in skeletal muscle, heart and fat. FATP1 is a metabolic regulator. FATP1-null mice are protected against diet-induced obesity and insulin resistance. In cultured skeletal muscle cells, FATP1 overexpression enhances FA uptake and storage as triacylglyceride, whereas FA oxidation is either not stimulated or only moderately enhanced. FATP1 strongly stimulates glucose oxidation and raises the activity of the pyruvate dehydrogenase (PDH) complex and pyruvate decarboxylase PDH-E1 catalytic subunit. FATP1 is immunolocalized in internal membranes and mitochondria, although the suborganelle compartment is unknown. We examined the mechanism of effect of FATP1 on PDH activity and submitochondrial localization of FATP1 in cultured skeletal muscle cells.
Materials and methods: FATP1 effects on PDH activity were analyzed after adenoviral-mediated transfer of the mouse FATP1 cDNA into cultured muscle cells. PDH complex and PDH-E1 subunit activities were determined by measuring the $^{14}CO_2$ production from [1-^{14}C]-pyruvate. Western blotting was used to assess PDH complex protein content and phosphorylated PDH-E1α at site 1 and site 2 using specific antibodies (kindly provided by Dr. H. Pilegaard). Subcellular and suborganelle immunolocalization was assessed in cells expressing FATP1 fused at the C terminus to EGFP using anti-GFP antibodies and electron microscopy.
Results: Overexpression of FATP1 in cultured myotubes raised the levels of the active form of the PDH complex and the PDH-E1 catalytic subunit, whereas no differences in the phosphorylation of PDH-E1α at site 1 or site 2 were observed. The levels of the active form of the PDH complex and the PDH-E1 catalytic subunit were not altered by incubation of myotubes with palmitate, oleate or their mixture. Palmitate partially counteracted the activation of the PDH complex and PDH-E1 catalytic subunit by FATP1, whereas oleate or the mixture of palmitate with oleate did not. Immuno-electron microscopy showed that FATP1-GFP was localized inside the mitochondria, within the inner membrane-matrix compartment, whereas GFP was localized intracytoplasmatically and in the nucleus.
Conclusion: In cultured skeletal muscle cells FATP1 activates the PDH complex and PDH-E1 catalytic subunit, without affecting the phosphorylation of PDH-E1α at site 1 or site 2. This activation is counteracted by palmitate. FATP1-GFP is localized in skeletal muscle cells inside the mitochondria, where the PDH complex lies. These data provide insight into how FATP1 activates the PDH complex.

Adipose tissue-specific cholesteryl ester transfer protein expression in mice: impact on glucose metabolism

H. Zhou[1], Q. Cui[1], X. Ju[1], W. Wang[1], J. Jiang[1], T. Yang[1], X.-C. Jiang[2];
[1]Endocrinology and Metabolism, the first affiliated hospital of Nanjing Medical University, China, [2]Anatomy and Cell Biology, State University of New York Downstate Medical Center, Brooklyn, USA.

Background and aims: Cholesteryl ester transfer protein mediates HDL cholesteryl ester delivery to the liver cells. Adipose tissue is a highly conserved site of cholesteryl ester transfer protein (CETP) expression across species, adipose tissue CETP makes a major contribution to CETP in the circulation. To investigate the impact of adipose CETP expression on adipocyte function and metabolism of glucose and lipid, we set up adipose tissue-specific CETP transgenic (CETPTg) mice.
Materials and methods: We created adipose tissue-specific CETP transgenic (CETPTg) mice successfully, using the aP2 promoter. HE-stained sections of adipose tissue from CETPTg mice and WT mice, in order to know the

change of adipocyte size, the frequency distribution of adipocyte cell surface area of both groups were evaluated. Then we evaluated the body weight and food consumption after four month chow diet or high fat diet. The glucose tolerance test and insulin tolerance test were all applied in CETPTg mice and WT mice after chow or high fat diet.
Results: CETP mRNA was predominantly expressed in adipose tissue in CETPTg mice. Plasma lipoprotein analysis showed marked reductions in HDL cholesterol ; and adipocytes were significantly smaller than those in control mice and stored less lipid than those of wild type mice. No differences were found between WT and CETPTg mice in body weight and food consumption after four month chow diet or high fat diet. Differences between the CETPTg and the WT littermates under chow diet were detected when a glucose tolerance test was administered. The blood glucose levels in the CETP Tg mice were higher than in WT mice after injection of a glucose solution. The differences were significant after 30 min and 60min of the test ($P< 0.05$), indicating that CETPTg mice displayed impaired glucose tolerance. In an insulin tolerance test, the CETPTg mice became significantly more hypoglycemic at 15, 30min after insulin injection than the WT mice ($P < 0.001$, $P < 0.05$ respectively), showed an increased sensitivity to insulin. The GTT and ITT were also investigated in the CETPTg and WT mice after high fat diet. The results indicated that the tendency was still there but without significance, high fat diet masked the effect of CETP overexpression.
Conclusion: GTT reflects both insulin sensitivity and insulin secretion, while ITT only reflects insulin sensitivity. Smaller adipocyte shows a higher insulin sensitivity. Adipose tissue-specific CETP overexpression reduced their adipocyte size with an increased insulin sensitivity, however the glucose tolerance was impaired. We predict that maybe there is problem with the beta cell function, we need to do further investigation in the next study.

Loss of pigment epithelium-derived factor deteriorates lipid and glucose metabolism
A.L. Birkenfeld[1], C. Chung[2], H.-Y. Lee[3], M.J. Jurczak[3], F.R. Jornayvaz[3], S. Crawford[4], G.I. Shulman[3], V.T. Samuel[3];
[1]Endocrinology and Clinical Nutrition, Charite University School of Medicine, Berlin Nuthetal, Germany, [2]Digestive Diseases, Yale University School of Medicine, New Haven, USA, [3]Endocrinology, Yale University School of Medicine, New Haven, USA, [4]Pathology, Northwestern University, Chicago, USA.

Background and aims: Pigment epithelium-derived factor (PEDF) is an endogenous protein with neuroprotective and anti-angiogenic effects. Experimental studies report that PEDF is a putative ligand for adipose triglyceride lipase. Clinical reports indicate that elevated serum PEDF may be a compensatory protein in the metabolic syndrome. However, the physiological significance of PEDF as a regulator of lipid metabolism is unknown. We hypothesized that deletion of PEDF promotes lipid accumulation and leads to insulin resistance
Materials and methods: PEDF deficient (PEDF ko) and age-matched control (WT) mice (n=8/group) were studied in metabolic cages on a regular chow diet, and an IPGTT (1 mg/g) was performed after an overnight fast.
Results: Compared to WT mice, energy expenditure was reduced 25% ($p<0.001$) in PEDF ko mice with a 50% decrease in food consumption ($P<0.01$) and total activity ($P<0.001$). Body weight was increased by 10% ($P=0.01$), and fat mass, as measured by 1H magnetic resonance spectroscopy, was more than two-fold higher ($P<0.001$) in PEDF deficient mice. PEDF ko mice had higher fasting glucose concentrations (156±8 vs 103±8 mg/dL, $P<0.001$), and marked hyperinsulinemia (58±2 vs 14±3 μU/ml, $P=0.02$), suggesting severe insulin resistance. During the IPGTT, the glycemic excursion was higher in the PEDF ko mice with an 80% increase in the AUC glucose, but without additional glucose stimulated insulin secretion.
Conclusion: Loss of PEDF promotes obesity and insulin resistance in mice.

Effect of RNAi-mediated gluconeogenic gene depletion on the fasting blood glucose level in alloxan-diabetic mice
K. Jin Hwa[1], B. HakYeon[1], K. SangYong[1], L. Byoung Rai[2];
[1]Department of Internal Medicine, [2]Department of Biochemistry, College of Medicine, Chosun University, Kwangju, Republic of Korea.

Background and aims: Glucose 6-phosphatase(G6Pase) catalyses the final reaction in hepatic glucose production by gluconeogenesis, and has been proposed as a potential target for antihyperglycaemic drugs for type 2 diabetes. PPAR gamma-coactivator 1(PGC-1) stimulatse this enzyme. To evaluate the potential of G6Pase and PGC-1 as a therapeutic target of type 2 diabetes, we investigated the response to dietary caloric restriction on the PGC-1 expression in liver of Otsuka Long-Evans Tokushima Fatty(OLETF) rats, and perfomed depletion of G6Pase and PGC-1 gene by siRNA-expressing plasmid DNA(siRNA-pDNA) injection in alloxan-diabetic mice.
Materials and methods: In OLETF rats and Long-Evans Tokushima Otsuka(LETO) rats, liver PGC-1 mRNA and blood glucose levels were investigated at 1, 2, and 3 weeks after the beginning of 30% caloric restriction(CR). siRNAs of G6Pase and PGC-1 were constructed to siRNA-pDNA. Each siRNA-pDNA was injected to alloxan-diabetic mice by tail vein and monitored blood glucose level. The levels of G6Pase and PGC-1 mRNA in liver of mice were measured by real time PCR.
Results: The liver PGC-1 mRNA expression were increased to 19% in LETO rats but significant change was not observed in OLETF rats by 30% CR. Postprandial blood glucose level was not changed between control and siRNA-pDNA(G6Pase, PGC-1) treated alloxan-diabetic mice. After 12 hour fasting, the blood glucose levels of control were 235±27 mg/dL. Each glucose levels of G6Pase and PGC-1 siRNA-pDNA injected alloxan-diabetic mice were 115±16 and 127±10 mg/dL at the same time. There were significant differences between control and experimental groups after 12 hour fasting. G6Pase and PGC-1 mRNA levels in liver of mice were decreased by injection of siRNA-pDNA.
Conclusion: Gluconeogenic gene such as G6Pase and PGC-1 depletion by siRNA-pDNA treatment leads to lowering fasting blood glucose levels in diabetic mice. This represents the potential of G6Pase and PGC-1 as a therapeutic target of type 2 diabetes.

718

Effects of high-fat diet on lipid metabolism in ApoE-/- mice
S. Xu[1], L. Li[1], G. Yang[2]
[1]The Key Laboratory of Laboratory Medical Diagnostics in the Ministry of Education, [2]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: High-fat diet (HFD) is associated with insulin resistance, hyperinsulinemia, elevated plasma free fatty acid (FFA), and increased risk for atherosclerotic vascular disease (ASVD). However, the mechanisms underlying the tissue-specific effects of HFD on the expression of genes involved in glucose and lipid metabolism have not been fully clarified. In our study, we have studied the effects of HFD on key enzymes and transcription factors involved in glucose and lipid metabolism in $ApoE^{-/-}$ mice.
Materials and methods: Twenty male $ApoE^{-/-}$ mice aging 8 weeks old were housed in individual cages and subjected to an environmentally controlled room with a 12-h light/dark cycle. Mice were randomly assigned to one of two groups. One for a normal chow diet (NC, n=10). The other for a high-fat diet (HF, n=10). Hyperinsulinemic-euglycemic clamp study was carried out. Plasma FFA, insulin concentrations (PIns), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), TG and TC concentrations were measured. The mRNA levels of insulin-induced gene (INSIG), sterol regulatory element binding protein cleavage activating protein (SCAP), sterol regulatory element binding protein-2 (SREBP-2), 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGCR) and low density lipoprotein receptor (LDLr) were determined by RT-QPCR; The concentrations of protein visfatin and FGF-21 were assay. The liver and adipose in mice ATGL, $INSIG_2$, FGF-21 and visfatin protein were measured by western blot.
Results: Whole body insulin sensitivity were evaluated by hyperinsulinemic-euglycemic clamp technique combined with [3-^{3}H] glucose as a tracer. The GIR in the HF group was markedly lower than in the controls ($P< 0.01$).Compared to controls, mice fed a high fat diet (HFD) had significantly increased body weight, fasting blood glucose (FBG) and plasma concentrations of insulin, FFA, TG, TC, HDL-C, and LDL-C ($P<0.01$,). The mRNA expression

of INSIG2 and SCAP was significantly up-regulated ($P<0.01$,) and INSIG2 protein level in liver was also increased in HF group ($P<0.05$). The mRNA expression of SREBP-2, HMGCR and LDLr was down-regulated in liver of HF group ($P<0.05$ and $P<0.01$). In adipose tissue, mRNA expression of INSIG1, INSIG2 and SCAP, and protein levels of INSIG2 were no differences between the two groups. The mRNA expression of SREBP-1, ATGL and PPARγ in liver and adipose tissues were significantly down- regulated in HF group than in NC group ($P<0.05$ and $P<0.01$). But FAS mRNA and HSL levels were no differences in two groups.
Conclusion: Hyperglycemia, dyslipidosis and hyperinsulinemia in this animal model might result from, at least in part, the changes of these key enzymes and transcription factors. Our findings might also account for the characteristics of glucose and lipid metabolism in diet-induced insulin resistance.

The lack of beta 2 adrenoceptors in mice results in glucose intolerance and impaired insulin secretion
A. Lombardi[1], G. Santulli[2], D. Sorriento[2], A. Anastasio[2], S. Iovino[1], C. Del Giudice[2], B. Trimarco[2], F. Beguinot[1], P. Formisano[1], C. Miele[1], G. Iaccarino[2];
[1]Dbpcm & ieos-cnr, "Federico II" University - Dpt. Cellular and Molecular Biology and Pathology, [2]DMCSCI, "Federico II" University - Dpt. Clinical Medicine, Cardiovascular & Immunologic Sciences, Naples, Italy.

Background: The reciprocal regulation of Sympathetic Nervous System and Insulin relays on molecular mechanisms that are not fully understood. Beta 2 adrenergic receptors (beta 2 ARs), in particular, are known to be involved in insulin production and in peripheral glucose uptake, but their role in development of diabetes is not clear.
Methods and results: We characterized the metabolic phenotype of mice (age 6 months) with deletion of the beta 2 AR gene (KO, n=21), performing tolerance tests to glucose (GTT, 1mg/Kg), insulin (ITT, 0.75 IU/Kg) and sodium pyruvate (PTT 2g/Kg) and hyperinsulinemic euglicemic clamps. As control we used C57BL/6 mice (WT, n=18). KO mice exhibited decreased glucose tolerance compared to WT mice (AUC GTT KO: 40980±6890 vs AUC GTT WT 19290±2120, p<0.01, ANOVA). However, ITTs showed that KO mice did not feature peripheral insulin resistance compared to WT mice (AUC ITT KO: 8280±1250 vs AUC ITT WT 13950±1815, p<0.01, ANOVA). Clamp studies in KO mice revealed a lower Glucose Infusion Rate (KO vs WT: 14.6±8 vs 30±9 mg/Kg/min), an increased endogenous glucose production: (79.8±4 vs 36.1±3 mg/Kg/min) and an increased rate of glucose disappearance (96.6±5 vs 63.2±3.4 mg/Kg/min; p<0.05), suggesting that insulin resistance develops at the hepatic level in KO mice compared to WT mice. KO mice showed impaired insulin response to hyperglycemia compared to WT mice. Histological analysis of pancreatic tissues displayed a normal architecture of the islets in both KO and WT mice. Also total insulin content (insulin KO: 4.93±0.87 ng/g of pancreas vs WT: 4.19±1.82 ng/g of pancreas) and glucagone content (glucagone KO: 577.8±106.5 pg/g of pancreas vs WT: 636.17±112.8 pg/g of pancreas) were comparable in both KO and WT mice. However, whilst in islets isolated from WT mice glucose induced insulin secretion by 3-fold, islets from the KO mice exhibited a blunted response to glucose. Glucagon secretion was not different in KO and WT mice. Increasing beta 2 AR expression in KO mice isolated islets by the infection of an adenoviral construct bearing the beta 2 AR cDNA, restored the ability of KO islets to secrete insulin in response to glucose.
Conclusion: Our results suggest that beta 2 AR plays a critical role in the regulation of glucose metabolism and insulin secretion both in vivo and ex vivo. These findings open new fields of investigation for the development of strategies to produce drugs with potential therapeutic applications in diabetes.

Folate deficiency increases adipose tissue and muscle insulin resistance in spontaneously hypertensive rats
M. Maxová[1], M. Pravenec[2], L. Kazdová[1];
[1]Institute for Clinical and Experimental Medicine, [2]Institute of Physiology, Czech Academy of Science, Prague, Czech Republic.

Background and aims: Controversial clinical data and a few studies in animal have been reported on the association between insulin resistance and plasma folate levels. The aim of this work was to compare the influence of the folate-deficient diet and high-fructose diet on insulin resistance parameters in spontaneously hypertensive rats (SHR), which are commonly used as a model of a metabolic syndrome.
Materials and methods: One group of adult male SHR rats (n=9) were fed a folate-deficient diet (Harlan Teklad, Netherlands) *ad libitum* for 4 weeks, the second group (n=9) were fed a high-fructose diet (70 cal.%). Triglycerides, glucose and free fatty acids concentrations were determined with commercially available kits (Pliva Lachema, Czech Republic; Roche Diagnostic GmbH, Germany, resp.). Serum folate levels were estimated by folate test AxSYM (Abbott Laboratories). Tissue insulin sensitivity was measured *in vitro* without or with insulin (250 μU/ml) according to basal and insulin-stimulated ^{14}C-U-glucose incorporation into muscle glycogen or adipose tissue lipids.
Results: After 4 weeks, the rats fed the folate-deficient diet has lower serum folate concentration in comparison with rats fed a high-fructose diet (11.07±0.47 nmol/l *vs* 75.96±3.46 nmol/l; p<0.00001). Animals fed with folate-deficient diet showed increased body weight (381±4.9 g *vs* 351±6.1 g; p<0.001), whereas epididymal fat pads weight when related to body weight were not different between groups. Nonfasting serum glucose levels were increased in the folate deficient rats (5.8±0.1 *vs* 4.99±0.2 mmol/l; p<0.0004). Surprisingly folate-deficient diet markedly decreased serum triglycerides concentrations (0.77±0.03 *vs* 2.14±0.17 mmol/l; p<0.000001) whereas free fatty acids were not different. There were found no significant differences in liver and muscles triglycerides concentrations between folate-deficient or fructose fed rats, however both groups showed hepatic steatosis as a results of increased triglycerides accumulation (17.69±1.30 *vs* 15.46±0.98 μmol/l, N.S.). The rats fed on the folate-deficient diet exhibited significantly decreased glucose incorporation into adipose tissue lipids and into muscle glycogen in comparison with fructose fed animals (Tab). The ability of insulin to stimulate glucose incorporation was lower in folate-deficient rats than in fructose fed rats.
Conclusion: Our results show that folate-deficiency impaired glucose sensitivity of peripheral tissues and stimulated hepatic steatosis similarly as fructose feeding and support hypothesis that folate deficiency may contribute to the pathogenesis of metabolic syndrome.

Enhanced neuronal NO Synthase breakdown through the ubiquitin-proteasome pathway in skeletal muscle of insulin resistant Zucker *fa*/*fa* rats
K. Mezghenna, M. Manteghetti, M. Tournier, P. Petit, R. Gross, A.-D. Lajoix;
CNRS UMR 5232, Montpellier, France.

Background and aims: In type 2 diabetes, due to a decrease in insulin sensitivity, glucose uptake is impaired in skeletal muscle. The latter is well known to express a splice variant of the neuronal isoform of NO Synthase (nNOS), nNOSμ. Because nNOSμ exerts a physiological role in the control of skeletal

muscle contractility and glucose uptake, we were prompted to investigate whether alterations of muscle nNOSμ could occur in prediabetic states and in the early phases of type 2 diabetes.
Materials and methods: We performed our study using Zucker *fa*/*fa* rats, characterized by a strong insulin resistance and hyperinsulinemia, two important features of prediabetic states. Zucker *fa*/+ lean rats were used as controls. nNOSμ catalytic activity was evaluated by measuring citrulline production from labelled arginine. nNOSμ expression was measured by quantitative PCR and western blotting. MG132 was used as an inhibitor of proteasomal function. Subcellular localization of nNOSμ was determined in immunofluorescence studies with specific antibodies.
Results: In skeletal muscle extracts from Zucker *fa*/*fa* rats, we found a 41% decrease in nNOSμ catalytic activity when compared to control *fa*/+ extracts ($p<0.01$). This decrease correlates with a significant 42% reduction in the enzyme proteic level ($p<0.05$) with no change in nNOSμ mRNA, which argues for the occurrence of an increased proteasomal breakdown. Use of the proteasomal function inhibitor MG132 in isolated skeletal muscle enabled us to bring evidence for an increased level of nNOSμ ubiquitination in *fa*/*fa* rats. In addition, inhibition of the ubiquitin-proteasome pathway resulted into a significant recovery of both nNOSμ proteic expression and catalytic activity, to levels similar to those recorded in *fa*/+ controls. In immunofluorescence studies, we could confirm the decrease in the expression nNOSμ protein in skeletal muscle of *fa/fa* rats; interestingly this decrease was found associated to a disturbance of the enzyme sub-membrane distribution.
Conclusion: In Zucker *fa/fa* obese insulin resistant rats, skeletal muscle displays a decreased nNOSμ catalytic activity resulting from an increased breakdown of the enzyme through the ubiquitin-proteasome pathway. These abnormalities, associated to a disturbed nNOSμ sub-membrane distribution, could be involved in the impaired skeletal muscle glucose uptake in the early phases of type 2 diabetes.

722

Analysis of insulin sensitivity in $p66^{shcA}$ KO mice by hyperinsulinaemic euglycaemic clamp
G. Sorice[1], S. Chiatamone Ranieri[2], G. Muscogiuri[1], A. Giaccari[1], G. Pani[2];
[1]Endocrinology, [2]General Pathology, Catholic University, Rome, Italy.

Introduction and aim: Emerging clinical and experimental evidence point to a major role of tissue oxidative stress in linking ageing and excess body weight with insulin resistance; molecular mechanism underlying this connection are however still elusive. The signaling adaptor protein $p66^{shcA}$ promotes mitochondrial generation of oxidant species in several models of age-related disease, and p66KO mice live 30% longer than their WT littermates; thus, this protein may represent a critical determinant of the intracellular redox-state imbalance associated with diabetes and metabolic syndrome. We have previously shown that genetically obese, hyperinsulinemic ($Lep^{Ob/Ob}$) mice lacking p66shcA are partially protected from glucose intolerance observed in their p66shc proficient littermates (Chiatamone et al., submitted), demonstrating that p66shc promotes insulin resistance in this setting. However, no major effects of p66shc on glucose homeostasis were detected in normal, lean mice by standard Intraperitoneal glucose tolerance test (ipGTT, 1g glucose/Kg BW) and insulin tolerance test (ITT, 0.75 U/Kg BW).
Methods and Results: Prompted by this discrepancy we have set up and performed hyperinsulinemic euglycemic clamp (18 $mUI \cdot kg^{-1} \cdot min^{-1}$) on lean mice of the two genotypes. This more reliable assay clearly demonstrated an enhanced insulin sensitivity in $p66^{shcA}$-/- mice in comparison to WT animals (M, as mg of glucose metabolized per kg of BW per minute, and SEM: respectively 161 $mg \cdot kg^{-1} \cdot min^{-1}$,± 35; 66 $mg \cdot kg^{-1} \cdot min^{-1}$,± 4.4; $p<0.02$). In keeping with this finding, biochemical analysis of the insulin signalling pathway in the adipose tissue of $p66^{shcA}$ null mice demonstrated reduced serine phosphorylation (serine 307+serine 636-639) of the insulin substrate IRS-1, an hallmark of insulin desensitization.
Conclusions: These findings confirm and extend our observation that $p66^{shcA}$ participates in the regulation of insulin action in an hyperinsulinemic setting, as it occurs in ageing-associated metabolic disorders including obesity and metabolic syndrome. While the possible connection between p66-dependent oxidative stress and insulin resistance needs to be further investigated, our data strongly encourage pharmacological research aimed at blocking the deleterious effect of the $p66^{shcA}$ protein to improve glucose homeostasis and prevent type 2 diabetes.

723

Lack of inducible nitric oxide synthase prevents lipid infusion-induced insulin resistance in mice
S.-Y. Park[1], H.-N. Cha[1], Y.-W. Kim[1], J.-Y. Kim[1], K.-C. Won[1], J.-M. Dan[2];
[1]College of Medicine, Yeungnam University, Daegu, [2]School of Medicine, Cha university, Gumi, Republic of Korea.

Background and aims: The role of inducible nitric oxide synthase (iNOS) on lipid-induced insulin resistance was examined in iNOS knockout (KO) mice and wild-type litter mate using hyperinsulinemic-euglycemic clamp technique.
Materials and methods: Four days before clamp, chronic catheter was inserted into jugular vein and connected to three-way to infuse insulin (15 $pmol \cdot kg^{-1} \cdot min^{-1}$) and 20% glucose on the day of clamp. After overnight fasting, 20% of intralipid and 33 U/ml of heparin were infused for 2 hours before and during clamp in lipid group, and saline was infused in saline group.
Results: Body weight was not different between wild-type and iNOS KO mice but epididymal fat mass was significantly elevated in iNOS KO mice. Glucose infusion rate (GIR) to maintain euglycemia was significantly reduced by lipid infusion in wild-type mice but GIR was not reduced by lipid infusion in iNOS KO mice. Lipid infusion produced whole body insulin resistance in wild-type mice but lack of iNOS prevented development of lipid infusion-induced insulin resistance. Whole body insulin resistance was contributed by 30% decrease in skeletal muscle glucose uptake in wild-type mice, whereas lipid infusion had no effect on glucose uptake of skeletal muscle in iNOS KO mice. Skeletal muscle insulin resistance was accompanied with decrease in glycolysis in lipid-infused wild-type mice. Plasma level of tumor necrosis factor-α was increased by lipid infusion in both iNOS KO and wild type mice. Proinflammatory cytokines in skeletal muscle and adipose tissue were also increased by lipid infusion in both groups. While nitrotyrosine level in skeletal muscle was increased by lipid infusion in wild-type mice, it was significantly lower in lipid-infused iNOS KO mice compared with lipid-infused wild-type mice.
Conclusion: These results suggest that lack of iNOS prevents whole body and skeletal muscle insulin resistance induced by lipid infusion, which may be contributed by reduced nitrosative stress.

Inhibition of PSGL-1-selectin pathway ameliorates obesity-related insulin resistance in db/db mice
D. Hirota, K. Shikata, C. Sato, R. Kodera, S. Miyamoto, N. Kajitani, T. Takatsuka, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Japan.

Background and aims: There have been accumulating evidences that inflammation in adipose tissue is involved in the mechanism of obesity-related insulin resistance. Macrophages and proinflammatory cytokines are increased in visceral adipose tissues of obese people and animal models. Infiltration of monocyte/macrophage is mediated by the interaction of cell adhesion molecules expressed on monocytes and endothelial cells. We previously screened the gene expression profiles in adipose tissues from obese mice using DNA microarray and found that P-selectin glycoprotein ligand-1 (PSGL-1) is upregulated in both db/db mice and high-fat diet (HFD) fed mice. PSGL-1 is expressed on both leukocytes and endothelial cells and binds to P-, L- and E-selectin. We found PSGL-1 is expressed on both endothelial cells and macrophages in adipose tissues of obese mice. Furthermore, we demonstrated that PSGL-1 deficient mice fed with HFD revealed decreased macrophage infiltration into adipose tissues, improved adipocyte hypertrophy and insulin resistance as compared with wild type mice fed with HFD. The aim of this study is to identify the inhibitory effect of the PSGL-1-selectin pathway using anti-PSGL-1 monoclonal antibody.
Materials and methods: Anti-PSGL-1 monoclonal antibody or normal rat IgG was administered by intraperitoneal injection to six week-old male db/db mice. An intraperitoneal insulin tolerance test (IPITT) and an intraperitoneal glucose tolerance test (IPGTT) were performed at 7 weeks old. We measured serum lipids, insulin, HbA1c and adipocytokines. We also examined the gene expression of proinflammatory cytokines, chemokines, adhesion molecules, adipocytokines and infiltration of macrophages in epididymal white adipose tissues (WAT). The size of adipocytes was measured and analyzed by morphometry.

Results: There was no significant difference in body weight, weight of epididymal WAT, total cholesterol, free fatty acid and HbA1c. Significant reductions were observed in fasting blood glucose (104.5 vs 138.5 mg/dl) and LDL cholesterol (6.25 vs 10.5mg/dl) in treated group (treated group vs control group, $p<0.05$). The average values of triglyceride and fasting IRI were decreased in treated group as compared with control group. The size of adipocytes in epididymal WAT was also significantly decreased in treated group as compared with control group. Glucose tolerance and insulin sensitivity were significantly improved in treated group in IPITT and in IPGTT. The expressions of MCP-1 and CD68 were decreased in treated group as compared with control group.
Conclusion: The administration with anti-PSGL-1 antibody revealed decreased macrophage infiltration in adipose tissues, improved adipocyte hypertrophy and insulin resistance in db/db mice. These results provide the direct evidence that PSGL-1-selectin pathway promotes the recruitment of macrophages into adipose tissue. PSGL-1 might be a novel target for the prevention of insulin resistance in obesity.

Decreased serum brain-derived neurotrophic factor concentration in young nonobese subjects with low insulin sensitivity
M. Karczewska-Kupczewska, A. Adamska, A. Nikolajuk, E. Otziomek, M. Górska, M. Straczkowski, I. Kowalska;
Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Poland.

Background and aims: Insulin resistance and type 2 diabetes are associated with an increased risk of neurodegenerative diseases. Brain-derived neurotrophic factor (BDNF) regulates neuronal diff0erentiation and synaptic plasticity and its decreased levels are supposed to play a role in the pathogenesis of Alzheimer disease and other disorders. Decreased circulating BDNF levels in obesity and type 2 diabetes were reported, however, it is unclear, whether BDNF might be associated with insulin resistance in young, nonobese population. The aim of the present study was to estimate serum BDNF concentration in apparently healthy, nonobese women divided into subgroups according to their insulin sensitivity.
Materials and methods: We studied 46 young (age: 25.15±5.16 years), apparently healthy, nonobese (BMI: 24.02±2.84 kg x m^{-2}) women with normal glucose tolerance. Anthropometric and biochemical parameters and serum concentrations of BDNF and adiponectin were measured. Insulin sensitivity was estimated with the euglycemic hyperinsulinemic clamp technique. Then, participants were divided into subgroups of high insulin sensitivity (high IS, above median from the clamp study, n=23) and low insulin sensitivity (low IS, below median, n=23).
Results: The difference in BMI and waist circumference between the groups did not reach the level of significance, whereas the percent of body fat was higher in the low IS group ($p=0.024$). We observed decreased serum BDNF concentration in women with low IS ($p=0.001$), which remained significant after adjustment for the difference in the percent of body fat. In the entire study population, serum BDNF was positively related to insulin sensitivity ($r=0.43$, $p=0.003$). In multiple regression analysis, this correlation remained significant after adjustment for other estimated parameters. In the low IS group, relationship between serum BDNF and adiponectin was also observed ($r=0.52$, $p=0.027$).
Conclusions: Our data show that serum BDNF is decreased in young nonobese women with low IS. Thus, early detection and prevention of insulin resistance might be useful in the prevention of neurodegenerative disorders.

Hypothalamic dysfunction in obesity as evaluated by functional magnetic resonance image
S.S. Lee, F.R.S. Pereira, D.E. Cintra, L.M. Li, F. Cendes, L.A. Velloso;
Unicamp, Campinas, Brazil.

Background and aims: Hypothalamic inflammation and dysfunction have emerged as important factors determining the loss of the coordinated control of caloric intake and energy expenditure in animal models of obesity. Here we use functional magnetic resonance image (fMRI) to explore the hypothesis that obese humans also present some degree of dysfunctional hypothalamic activity.
Materials and methods: Functional images were acquired during a resting state paradigm before and after an oral glucose load. The BOLD signal was recorded for five minutes before and 25 minutes after glucose ingestion, and the Kendall's coefficient of concordance was estimated.
Results: Twelve obese patients undergoing bariatric surgery were submitted to fMRI before surgical procedure and approximately eight months after surgery, when absolute body mass was reduced by 29±4%. Eight age-matched lean controls were evaluated by the same method. Nutritional evaluation at enrolment revealed a mean caloric intake of 5,600±3,400 kCal/day, with high consumption of saturated fat. After surgery, mean caloric intake dropped to 805±350 kCal/day, with substantial reduction of the consumption of saturated fat. Caloric intake of lean subjects was 2,380±850 kCal/day. Reduction of body mass was accompanied by significant reductions of blood insulin and leptin and by the increase of adiponectin. In addition inflammatory markers such as C-reactive protein and blood leukocyte counts were significantly reduced. The comparison of obese patients before surgery with lean controls

revealed a significantly reduced loss of local homogeneity (t-score -8.71, p<0.05) in the hypothalamus (a representative image showing areas with loss of homogeneity in color is depicted in the accompanying figure). After surgery this loss of homogeneity was not so pronounced but still significant (t-score -7.30, p<0.05). Finally, when comparing obese patients before and after surgery a significant change in the loss of homogeneity was detected with a higher score in the post-surgical acquisition (t-score -4.64, p<0.05).
Conclusion: Although the loss of homogeneity in the hypothalamus was still smaller in the post-surgical group than in lean subjects, it is clear that the reduction of body mass was somehow correlated with a modification in the functional pattern of the hypothalamus towards the lean subjects standard. Thus, hypothalamic function, as determined by fMRI differs obese and lean subjects, and massive body mass loss produced by bariatric surgery leads to significant change in this parameter. fMRI may become an attractive, non-invasive method to study central nervous system function in metabolic diseases.

Deep brain stimulation in patients with Parkinson's disease: involvement of local brain regions in systemic glucose metabolism?
N.M. Lammers[1], B.M. Sondermeijer[2], T.B. Twickler[3], R.M.A. de Bie[4], M.T. Ackermans[5], E. Fliers[1], S.E. la Fleur[5], M.J.M. Serlie[1];
[1]Endocrinology & Metabolism, [2]Vascular Medicine, [3]Vacular Medicine, [4]Neurology, [5]Clinical Chemistry, Laboratory of Endocrinology, AMC, Amsterdam, Netherlands.

Background and aims: We have previously shown that schizophrenic drug-naïve patients display hepatic insulin resistance, suggesting that central dopamine signaling is involved in the regulation of endogenous glucose production (EGP). As a first step to test this hypothesis in an experimental setting, we studied whether deep brain stimulation (DBS) in the subthalamic nucleus of patients with Parkinson's disease results in a change in basal EGP or hepatic insulin sensitivity.
Materials and methods: We studied 6 patients with Parkinson's disease treated by DBS both in the basal state and during a low-insulinemic euglycemic clamp using stable isotopes with DBS switched on or off. Each subject served as his own control and studies were performed in random assignment. We measured EGP and hepatic insulin sensitivity as well as resting energy expenditure (REE), glucoregulatory hormones and the Unified Parkinson's Disease Rating Scale (UPDRS).
Results: We included 6 men (age 60 [44-65] years and BMI 28.2 [22.6-33.1] kg/m^2). REE was not significantly different between the on and the off-situation. UPDRS was significantly higher when DBS was switched off. There was no significant difference in glucoregulatory hormones in either state. Basal plasma glucose and EGP (after 15 hrs of fasting) did not differ when DBS was switched on or off (EGP on 8.32 ± 0.73 and off 8.22 ± 1.09 μmol/kg·min, p=0.68). Hepatic insulin sensitivity did not significantly change (EGP on 3.15 ± 1.07 and off 2.8 ± 0.91 μmol/kg·min, p=0.36).
Conclusion: Deep brain stimulation of the subthalamic nucleus in patients with Parkinson's disease does not influence basal endogenous glucose production or hepatic insulin sensitivity.

Reduced hypothalamic insulin receptor expression and insulin-dependent Akt phosphorylation in a type 2 diabetes model associated with a defect in serotonergic system
K. Gerozissis[1], F. Berthou[1], C. Rouch[2], N. Vicaire[1], I. Papazoglou[1], D. Bailbe[3], B. Portha[3], M. Taouis[1];
[1]Neuroendocrinologie Moléculaire de la Prise Alimentaire,University Paris 11, CNRS CNPS UMR 8195, Orsay, [2]Unité BFA - Université Paris 7, [3]B2PE Unité BFA - Equipe 1, Université Paris 7, France.

Background and aims: Insulin resistance both in the periphery and the brain act synergistically in the induction of metabolic diseases (MD) and co-morbidities. Previous own studies and literature suggest a cross-talk between insulin and the neurotransmitter serotonin (5HT), a regulator of energy and glucose homeostasis, key element in depressive syndromes. In the present study, using a T2D model, the Goto Kakizaki (GK) rat, we focused on hypothalamic and liver insulin signalling and on the impact of 5HT.
Materials and methods: Male Wistar (W) or GK , 8-12 weeks old rats. Insulin receptor (IR) and Phospho-Tyrosine Phosphatase 1B (PTP-1B) protein expression or phosphorylation of Akt (a downstream protein kinase in IR/IRS/PI3K signalling pathway), following ip injection of either insulin (1 U/kg) or dexfenfluramine (stimulator of 5HT, 5 mg/ Kg) 30 min before euthanasia, was assessed by western blot. Endocrine and metabolic parameters were determined with appropriate methods. Statistical significance was set at p<0.05. N= 5-10.
Results: Compared to age matched W, glycemia, insulinemia and leptinemia was increased in GK rats. In W and GK rats, dexfenfluramine increased insulinemia and glycemia but did not alter leptinemia. Glycemia was increased more in GK as compared to W. IR protein expression was lower in GK liver and hypothalamus. In the hypothalamus, insulin injection induced Akt phosphorylation only in W rats. In liver, GK exhibits higher expression of PTP-1B associated to a lower insulin-dependent Akt phosphorylation, as compared to W. Finally, dexfenfluramine stimulated Akt phosphorylation only in the hypothalamus of W rats.
Conclusion: In diabetes, tissue specific alterations in insulin signalling occur within peripheral tissues. Here, were observed important alterations in hypothalamic and hepatic insulin signalling. In spite of inefficient insulin-induced Akt phosphorylation in GK probably due to altered IR and higher expression level of PTP1B, insulin lowered glycaemia, confirming that insulin resistance is not yet totally established in young adult GK. The effect of serotonin on central insulin signalling in W, reported for the first time, extends previous own work shown central insulin-serotonin interaction. The impact of the serotonergic system in GK was altered. In fact, it failed to phosphorylate hypothalamic Akt and increased glycemia in diabetic rats in higher levels than in Wistar, suggesting an exaggerated counter-regulatory effect. This study points out the complexity of insulin-serotonin cross-talk on molecular mechanisms potentially linking depressive disorders and diabetes.
KG and FB, participated equally.

Sucrose-induced insulin resistance is accompanied by morphologic and functional changes in the adrenal cortex of the rat
C. Martinez Calejman[1], F. Astort[1], E.M. Repetto[1], R. Sanchez[1], J.M. Di Gruccio[1], C.B. Cymeryng[1], P. Arias[2];
[1]Human Biochemistry Department, University of Buenos Aires - School of Medicine - CEFYBO- CONICET, [2]Physiology and Biophysics Department, University of Buenos Aires -School of Medicine, Argentina.

Background and aims: Hyperactivation of the hypothalamic-pituitary-adrenal (HPA) axis has been widely described in both human and animals showing insulin resistance (IR). However, a direct effect of the biochemical abnormalities that characterize this syndrome (e.g. elevated plasma glucose, serum insulin and free fatty acid levels, hypertriglicerydemia and oxidative stress) on adrenal function has not been elucidated yet. In this study we assessed the effect of a sucrose-enriched diet (SED) on adrenocortical structure and function (corticosterone secretion) in rats.
Materials and methods: Male Wistar rats were fed a sucrose-enriched diet (SED, drinking water contaning 30% w/v sucrose) up to 12 weeks. Rosiglitazone (4mg/kg, orally and daily) was administered throughout the duration of the sucrose treatment to a group of animals. Protein levels of different isoforms of nitric oxide synthase (NOS), phosphorylated Akt and cyclooxygenase 2 (COX-2) were analyzed by immunoblot while mRNA levels of steroidogenic

acute regulatory protein (StAR) and the macrophage marker F4/80 were assessed by semiquantitative RT-PCR. Steroid levels were determined by RIA. Sudan III staining was performed on adrenocortical slices previously fixed in 4% formaldehyde.
Results: As compared to controls, rats under SED for 7 weeks showed higher fasting plasma glucose (74 ± 5 and 130 ± 6 mg/dl; p<0,001, Mann-Whitney test) and serum triacylglyceride (104 ± 52 vs.604 ± 60 mg/dl; p<0,001) and insulin concentrations (0.99 ± 0.14 vs. 1.97 ± 0.4 ng/ml; p<0,005). An impairment in the insulin signalling pathway was detected at adrenal level as decreased p-Akt protein levels were measured by immunoblot analysis. The adrenal glands were lighter and showed a significant lipidic infiltration, as demonstrated by histochemistry. NOS activity and the expression levels of eNOS, iNOS and COX-2 were increased in the SED group. StAR and F4/80 mRNAs were also elevated. These animals showed significantly elevated basal serum corticosterone levels (6,63 ± 1,14 vs. 9,62 ± 0,84 ng/ml p<0,001) but a lower response to an acute stimulation with 4 UI/kg ACTH i.v., (115,68 ± 34, 03 vs 40,59 ± 25,39 percentage stimulation, p<0,05). On another set of experiments, rosiglitazone, a selective PPARgamma agonist, reverted the nutritionally-induced changes in NOS activity and corticosterone levels and decreased lipid infiltration in the adrenal tissue.
Conclusions: A sucrose enriched diet seems to induce IR at adrenal level after 7 weeks of treatment, generating morphological and functional disturbances that finally could lead to the dysregulation of adrenal steroidogenesis. In this sense, the increase in NOS activity could trigger posttranscriptional modifications of several proteins (nitration, S-nitrosilation etc). Among them, those involved in steroid biosynthesis and its regulation. Both COX-2 and F4/80 could also be related to the chronic inflammatory state linked to IR in several tissues. Finally, some of these effects were prevented by rosiglitazone treatment, suggesting a signal transduction pathway that could be a target for pharmacological interventions designed to ameliorate this adrenal disfunction.

Glucose metabolism and cognitive dysfunction
A. Backeström[1], S. Eriksson[2], L.-G. Nilsson[3], L. Nyberg[4], T. Olsson[5], O. Rolandsson[1];
[1]Department of Public Health and Clinical Medicine, Family Medicine, Umeå, [2]Department of Community Medicine and Rehabilitation, Geriatric Medicine, Umeå, [3]Department of Psychology, Psychology, Stockholm, [4]Department of Radiation Sciences, Umeå University, Psychology, [5]Department of Public Health and Clinical Medicine, Medicine, Umeå, Sweden.

Background and aims: The association between type 2 diabetes and different forms of cognitive impairment is well established. The mechanism behind the association is however still unrevealed. We have recently reported that raised blood glucose levels were associated to impairment in episodic memory, the memory function first affected in the progress to dementia. However, patients with type 2 diabetes have not only elevated levels of blood glucose, but also increased levels of insulin because of insulin resistance. It has been suggested that insulin itself might have a negative effect on cognitive function and memory. Diabetes is associated with a long standing hyperglycaemia but also with hypertension and hyperlipideima, leading to micro and macro vascular disease. Thus, our aim was to study whether insulin affects episodic memory independently of glucose in a nondiabetic adult population.
Materials and methods: We linked and matched two large population based data sets in Sweden, the Betula study and the Västerbotten Intervention Program. We identified 364 (F/M 207/157, mean age 50.5 ±8.0 years) nondiabetic subjects, free from dementia, who had participated in the two surveys within six months. The memory test included testing of episodic memory. We transformed the results using the mean values and standard deviation from the youngest age group to compute a composite *z*-score (subjects' value minus mean score in the 40-year-old group divided by SD). Fasting plasma insulin (FPI) and glucose (FPG) were analyzed with standard methods.
Results: Women had higher levels of episodic memory (mean z-score -0.06, SD 0.54) compared to men (mean z-score -0.36, SD 0.51, p<0.001). Given the sex difference in the outcome variable we stratified for sex. In a univariate linear regression both FPG (B -0.274, SE 0.068, Beta -0.271, p<0.001) and FPI (B -0.389, SE 0.131, Beta -0.204, p=0.003) were significantly associated with episodic memory in women but not in men. FPG, but not FPI, remained significantly associated with episodic memory after adjustment for hypertension, total P-cholesterol, bodymass index, educational level, depression, smoking and cardiovascular disease (FPG: B -0.218, SE 0.070, Beta -0.220, p=0.002; FPI: B -0.232, SE 0.149, Beta -0.127, p=n.s.), when FPG and FPI were analyzed separately. Entering both FPG and FPI into the regression model did not attenuate the association between FPG and episodic memory (FPG: B -0.204, SE 0.071, Beta -0.206, p=0.005).
Conclusion: We conclude that an increase in plasma glucose, but not plasma insulin, is associated with impairment in episodic memory in women. This could be explained by a negative effect on the hippocampus caused by raised plasma glucose levels.

Cognitive function in older adults with type 2 diabetes
E. Lopez Gonzalez, A. Luongo, A. Garcia, S. Milrad, M. Varela, M. Ruiz Morosini, DECOyDI;
Sociedad Argentina de Diabetes, Buenos Aires, Argentina.

Background and aims: Several studies have reported increased risk of Cognitive Dysfunction (CD) and dementia in people with Type 2 Diabetes (DM2). The outcome of these research efforts indicate that several causes may affect CD, include many pathophysiologic mechanisms and risk factors. We investigated DM2 as a risk factor for CD when compared with control group. Describe the frequency of DC in patients with DM2 and its relationship to education, income, physical activity, alcohol consumption, cardiovascular risk factors and depression.
Materials and methods: Cognitive function was assessed using the test Mini Mental State Examination (MMSE) and defined by scores (normal 28-30, mild cognitive dysfunction (MCD) between 27 to 24, and severe cognitive dysfunction (SCD) 9 points and pathological 65 years old and control group. The study was carried out by 17 Argentinean doctors specialized in Diabetes from the provinces of Buenos Aires, Salta and Buenos Aires City (Argentina). The evaluation included the following items: anthropometric measures, laboratory, level of education, life style and income. Chi2, Wilcoxon test and Multiple Logistic Regression were the tools used for the statistical analysis.
Results: 748 patients were included: DM2 (DMG) n=433 and control group (CG) n=315. Mean age=71.83 ± 5.58 in DMG and 71.79 ± 5.51 years in CG (p>0.92). In DMG the duration of diabetes 11.78 ± 9.17 years, the average HbA1c was 7.15 ± 2.73. The alcohol consumption was 48.73% in the DMG and 46.98% in CG. Education under 7 years was 40.8% in DMG vs. 35.67% in CG (p=0.39). The monthly income < 300 euros was 27.48% in DMG and 27.94% in CG (p=0.87). Depression was present in 18.2% of DMG and 12.4% of CG. SCD was present in 21.3% of DMG and 14.6% of CG and MCD in 35.3% of DMG and 31.7% of CG (p<0.0018). In women, diabetes acted as a risk factor for cognitive dysfunction (crude OR=2.13, 95% CI=1.46-3.11, p<0.0001). In men the mentioned above relation was not statistically significant (crude OR=1.14, 95% CI=0.71-1.85; p=0.57). In multivariate analysis, cognitive dysfunction in women was related with the presence of DM2 (adjusted OR=1.91; CI=1.26-2.90; p=0.002), low education level (OR=3.96; CI=2.55-6.13, p<0.0001), low-income (OR=2.06; CI=1.29-3.26; p=0.002), depression (OR=1.83; CI=1.08-3.04, p=0.026) and alcohol use (OR=1.57M; CI=1.01-1.45; p=0.04). In multivariate analysis, independent predictors of cognitive decline in men were low education (OR=4.9; CI=2.28-6.88; p<0.0001), low-income (OR=2.33; CI=1.14-4.58; p=0.01) and age (OR=2.25; CI=1.08-3.20; p=0.02).
Conclusion: The outcomes of our study indicate that DM2 in women increased the risk of CD. The low education level, low income, presence of depression and alcohol consumption were independent risk predictors. DM2 in men was not a predictor of CD in this sample. Low education, low income, and age were independent risk predictors of CD in men.

Brain volume changes in type 1 diabetes mellitus patients with microangiopathy are related to poorer cognitive functioning
E.H. Serné[1], I.C. Sluimer[2], H. Vrenken[2], E. van Duinkerken[3,4], R.G. IJzerman[3], M. Klein[4], F.J. Snoek[4], F. Barkhof[2], M. Diamant[3];
[1]Department of Internal Medicine, [2]Department of Radiology, [3]Diabetes Centre / Department of Internal Medicine, [4]Department of Medical Psychology, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Type 1 diabetes (T1DM) has been associated with lower amounts of brain volume as compared to matched healthy controls.

Furthermore, T1DM is associated with cognitive impairment, most pronounced in patients with microangiopathy. Here, we hypothesized that brain volume loss would be most marked in T1DM patients with microangiopathy and would be associated with impaired cognitive functions. Using magnetic-resonance imaging (MRI), we quantified grey and white matter volume and total brain volume and performed a neuropsychological assessment in 155 T1DM patients with and without microangiopathy and matched healthy controls.
Materials and methods: Fifty-one T1DM patients with and 53 without microangiopathy, and 51 matched healthy controls underwent a detailed neuropsychological assessment including the domains of general cognitive ability, memory, information processing speed, executive functions, attention, motor and psychomotor speed and a MRI-scan. This MRI-scan consisted of 10 different sequences to detect differences in cerebral structure and function among which was a T1 Magnetization Prepared Rapid Gradient Echo (MP-RAGE) for the estimation of both grey and white matter volume and total brain volume. Volumes were estimated using the Structural Image Evaluation, using Normalisation, of Atrophy (SIENAX) tool in the FMRIB Software Library (FSL4.1). This tool enables reliable estimation of brain volume by controlling for differences in brain size.
Results: Both grey matter volume and total brain volume were significantly decreased in T1DM patients with microangiopathy, compared to T1DM patients without microangiopathy and healthy controls (both $P < 0.05$). However, these differences were lost when controlling for age. In T1DM patients with microangiopathy a moderate positive correlations between motor speed and both white matter volume and total brain volume was found. T1DM patients without microangiopathy demonstrated a small positive correlation between motor speed and white matter volume ($P < 0.05$). In controls no correlations were found between brain volumes and cognitive function domains.
Conclusion: After correction of age, no differences in brain volume could be detected between T1DM patients with and without microangiopathy and healthy controls. Nevertheless, in T1DM patients positive correlations of MRI-measured brain volumes and motor speed could be demonstrated. These data may suggest that loss of brain volume is associated with poorer cognitive performance in this domain, although no causal relationships can be established. Longitudinal studies are warranted to confirm and expand these findings, to further detail the underlying mechanisms and to define their impact on patients, in terms of clinical consequences and quality of life.

Cerebral functioning is associated with carotid intima media thickness in uncomplicated type 1 diabetes mellitus

R.G. Ijzerman[1], E. van Duinkerken[1,2], M. Klein[2], E.H. Serné[3], N.S.M. Schoonenboom[4], J. Boerop[1], F.J. Snoek[2], C.J. Stam[4], M. Diamant[1];
[1]Diabetes Centre / Department of Internal Medicine, [2]Department of Medical Psychology, [3]Department of Internal Medicine, [4]Department of Clinical Neurophysiology / MEG Centre, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Measures of subclinical atherosclerosis, including carotid intima media thickness (cIMT), have shown to negatively affect brain function and structure in the general population. In type 1 diabetes (T1DM), an increased cIMT has been reported, but it is unknown whether cIMT is associated with cerebral function and activity in these patients and whether this association is affected by the additional presence of microvascular complications.
Materials and methods: We investigated 51 T1DM patients with proliferative diabetic retinopathy or other microvascular complications, as a marker of microangiopathy (DRP), 54 without microangiopathy (non-DRP), and 51 gender-matched controls. We measured cIMT using ultrasound and neuropsychological functions like memory, information processing speed, executive functions, attention, motor and psychomotor speed and general cognitive ability. Functional brain connectivity, an estimate of cerebral communication, was assessed using magnetoencephalography. Linear regression was used to determine the association between cIMT, cognitive functions and functional connectivity.
Results: In the non-DRP group, but not in DRP patients, cIMT was negatively associated with general cognitive ability, information processing speed and attention (all $P<0.05$). Also, in non-DRP patients a positive association of cIMT and functional connectivity for the delta-band, representing communication within both hemispheres and a negative association for the upper gamma-band, regarding interhemispheric communication were found (both $P<0.05$). Except for information processing speed all associations were independent of age, gender, diabetes duration and onset age.
Conclusion: In uncomplicated T1DM patients, but not in patients with microangiopathy, cIMT was inversely associated with cognitive functioning and related to aspects of functional connectivity, previously linked to cerebral pathology and changes in cognitive functions. Taken together, these findings suggest that, in T1DM patients without microangiopathy, subclinical atherosclerosis may exert a negative effect on the brain, whereas in T1DM with microangiopathy the impact of cIMT seems subordinate to other factors.

Comprehensive neuropsychological assessment of patients with longstanding type 1 diabetes mellitus with and without microangiopathy

M. Klein[1], E. van Duinkerken[2,1], M. Diamant[2], E.H. Serné[3], R.G. IJzerman[2], F.J. Snoek[1];
[1]Department of Medical Psychology, [2]Diabetes Centre / Department of Internal Medicine, [3]Department of Internal Medicine, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Type 1 diabetes (T1DM) is associated with mild cognitive decrements, and more so in the presence of proliferative retinopathy (DRP) as was shown in a small study comparing DRP patients with patients without DRP (non-DRP) and controls. In the present study, we hypothesized that T1DM patients with DRP would show cognitive decrements compared to T1DM patients without DRP and other microvascular complications and controls.
Materials and methods: Fifty-one DRP patients, 54 non-DRP patients and 51 controls underwent a comprehensive neuropsychological assessment, covering the domains general cognitive ability, memory, information processing speed, executive functions, attention, motor and psychomotor speed. Prior to assessment, blood glucose level of T1DM patients had to be in the range of 4-15 mmol/l and hypoglycaemic events 24 hours prior to assessment resulted in rescheduling the assessment. MANCOVA corrected for age, depressive symptoms and multiple comparisons was used to determine group differences and regression analysis to identify determinants of cognitive decrements.
Results: T1DM patients as one group compared to controls showed decrements in general cognitive ability, memory, information processing speed, motor and psychomotor speed (all $P\neg<0.05$). Effect sizes ranged from 0.3 - 0.6. Gender, proliferative DRP, blood pressure and blood glucose level were independent predictors of these decrements. When separating both T1DM patient groups, DRP patients were found to be oldest, reported most depressive symptoms, had longest disease duration and earliest age of diabetes onset. Both non-DRP and DRP patients showed reduced information processing speed compared to controls, with DRP patients showing the largest deterioration. DRP patients also showed decrements in memory, motor and psychomotor speed compared to controls and in attention and general cognitive ability compared to non-DRP and controls (all $P\neg<0.05$).
Conclusion: In this large sample, we showed that T1DM patients as compared to controls are susceptible to cognitive decrements. Furthermore, patients with DRP seem to be at the highest risk to develop cognitive decrements. Interestingly, patients without microangiopathy appear also susceptible to loss of processing speed, suggesting that selective cognitive functions are affected before microangiopathy becomes manifest.

Apical sodium-dependent bile transport inhibitors is identified as potential antidiabetic agents: parallels with metformin

B.R. Gedulin, G. Gedulin, E.K. Austin, A.A. Young;
Physiology, Satiogen Pharmaceuticals Inc., San Diego, USA.

Background and aims: The presence of bile acids (BA's) in the distal gut powerfully stimulates secretion of GLP-1 and other peptides from enteroendocrine L-cells. An effect of metformin is the inhibition of bile acid reuptake, which is mediated via apical sodium-dependent bile transporters (ASBT) in the ileum. Especially in the presence of dipeptidyl peptidase-IV inhibition (DPP4i), metformin stimulates secretion of L-cell products, including GLP-1.
Materials and methods: To probe the hypothesis that metformin's therapeutic effects are mediated via ASBT inhibition, we compared the dose-dependence of secretion of active GLP-1 in fasted normal rats pre-treated with a DPP4i (sitagliptin) and orally administered metformin (0, 30, 100, 300 mg/kg) or a non-absorbable ASBTi (SC-435; doses 0, 3, 30, 100 mg/kg). In db/db mice we tested the effects of orally administered metformin (0, 3, 30, 100, 300 mg/kg; n=5-12/group) and SC-435 (0, 3, 30, 100 mg/kg; n=9-12/group) on glucose level and 48 hour body weight.
Results: SC-435 dose-dependently increased 5-hour integrated GLP-1 concentrations 2.5 to 3.2 fold (-/+ DPP4i, respectively) vs vehicle, and metformin evoked 3.3 to 4.3 fold increases. SC-435 was ~1.6 fold more potent than metformin. Peak [GLP-1] of 30-36 pM observed 4-5 hours after metformin or SC435 in the present studies may promote antidiabetic and weight-loss effects otherwise only attainable with injected GLP-1 agonists. In db/db mice, a 7.9 mg/dL reduction in 24-hour plasma glucose invoked by 30 mg/kg valine-pyrolidide (a DPP4i) was amplified up to 3.8 fold by the addition of SC-435 This exceeded the antidiabetic effect of metformin in this model. Both SC-435 and metformin (+DPP4i) dose-dependently reduced body weight (by up to 5.2%, 4.3% respectively) over 48 hours in db/db mice, SC 435 being 10.5 fold more potent.
Conclusion: In summary, the parallel behavior of metformin and a non-resorbable bile salt transport inhibitor to stimulate GLP-1 secretion, to lower plasma glucose, to lower body weight, and to elevate BA's in the distal bowel, are consistent with their actions being via indirect L-cell stimulation with BA's. These studies further identify ASBTi's, including those without systemic exposure, as a potentially new class of oral antidiabetic antiobesity agent.

Effects of angiotensin II on receptor mediated insulin transcytosis in bovine aortic endothelial cells

W.C. Ha[1], S.J. Oh[1], J.I. Lee[1], J.H. Kim[1], S.A. Chang[1], O.K. Hong[1], B.Y. Cha[1], H.W. Lee[2], H.S. Son[1];
[1]The Catholic University of Korea, Seoul, [2]Yeungnam University Medical Center, Daegu-si, Republic of Korea.

Background and aims: Angiotensin II(ATII) is involved in the pathogenesis of hypertension and increases insulin resistance. It is known that the main role of insulin receptor in endothelial cells is to deliver insulin to target tissue by a series of process - binding of insulin on insulin receptor, internalization of insulin-insulin receptor complex and releasing of insulin around target tissue - called receptor mediated transcytosis. We investigated the effects of ATII on receptor mediated insulin transcytosis in endothelial cell.
Materials and methods: After treating with {insulin alone}, {insulin and ATII}, {insulin, ATII and angiotensin receptor blocker(ARB)} on bovine aortic endothelial cells, we observed the change of the total amount of insulin receptor, the amount of insulin receptor on membrane and in cytosol, binding of insulin on insulin receptor and internalization of insulin-insulin receptor complex, time dependently.
Results: 1) Insulin increased the total amounts of insulin receptor, binding of insulin on insulin receptor and internalization of insulin-insulin receptor complex. 2) ATII decreased the total amount of insulin receptor, and it decreased the binding of insulin on insulin receptor up to 70 %. 3) After treating with ATII, the amount of insulin receptor on cell membrane was decreased but the amount of insulin receptor in cytosol was increased, time dependently. 4) ATII decreased the internalization of insulin-insulin receptor complex, but the difference is imperceptible. 5) ARB improved the ATII- induced reduction of binding of insulin on insulin receptor up to 30 %.
Conclusion: It seems that ATII inhibits the receptor mediated insulin transcytosis in endothelial cell by reducing the binding of insulin on insulin receptor, and ARB improves this inhibitory effect. We think that this inhibitory effect is due to reduction of the amount of insulin receptor on cell membrane by reduction of the expression of insulin receptor and increase of the translocation of insulin receptor from cell membrane to cytosol. As a result, the delivery of insulin around target tissue is decreased, and this may explain partially insulin resistance by ATII.

737

Taurine improves hepatic insulin resistance induced by free fatty acid through inhibiting c-Jun NH2-terminal kinase 1(JNK1) pathway and improving insulin signalling

N. Wu, P. Han, S. Zhao, L.l. Zhou, Y. Li;
Department of Endocrinology, Shengjing Hospital of China Medical University, China.

Background and aims: It is well established that elevated circulating free fatty acids (FFA) can induce hepatic insulin resistance, which is the primary contributor to increased hepatic glucose production and overt hyperglycemia in type 2 diabetes. However, the exact mechanism by which FFAs cause insulin resistance in the liver is not completely known, but may involve oxidative stress. Intralipid plus heparin (IH) infusion is a standard nontoxic method to elevate FFA levels in vivo. Therefore, we established an in vivo model of insulin resistance by prolonged (48h) IH infusion in wistar rats. And co-infusion with taurine (an antioxidant) was designed to investigate the effects of taurine on hepatic insulin resistance, and to explore the potential mechanism of IH-induced hepatic insulin resistance in prolonged lipid infusion model.
Materials and methods: Cannulated rats (n=12-14/group) were infused for 48h intravenously with saline(SAL), or intralipid plus heparin (IH), or IH plus taurine (IHT), or taurine (TAU). Half of each group rats were randomly assigned to either the basal group or a clamp group. During the last 2h of the 48h infusion, hyperinsulinemic-euglycemic clamps with [6-^{3}H] glucose infusion (20μCi bolus followed by constant infusion at 0.4 μCi/min) were performed to assess hepatic insulin sensitivity. Oxidative stress measured as the concentration of 8-Iso-Prostaglandin F2a (8-iso-PGF2α) in liver was analyzed using anenzyme-linked immunoassay (ELISA) commercial kit. We evaluated JNK1 activation, insulin-stimulated IRS-1 tyrosine phosphorylation and insulin-stimulated IRS-2 tyrosine phosphorylation in the liver by immunoprecipitation and immunoblotting.
Results: The results showed during hyperinsulinemic-euglycemic clamp, IH infusion induced hepatic insulin resistance as indicated by elevation of HGP compared with SAL. Taurine prevented the elevation of HGP induced by IH infusion (HGP in umol/kg.min, SAL: 25±4 , IH: 71±6 , IHT: 30±7 , TAU: 26±4 , $p<0.05$ IH vs. other treatment groups). This indicates that IH-induced hepatic insulin resistance was abolished with taurine co-infusion. Furthermore, taurine co-infusion reversed IH-induced 1) increase in 8-iso-PGF2α, 2) increase in JNK1 activity, 3) decrease in insulin-stimulated tyrosine phosphorylation of IRS-2 in liver. Insulin-stimulated tyrosine phosphorylation of IRS-1 in liver did not differ among the four groups in this study.
Conclusion: In summary, prolonged IH-infusion induced the impairment of hepatic insulin sensitivity probably by activating JNK1 pathway and reducing the insulin-stimulated tyrosine phosphorylation of IRS-2 in liver. Taurine, as an antioxidant, prevented hepatic insulin resistance might also associated with inhibiting JNK1 and increasing insulin-stimulated tyrosine phosphorylation of IRS-2 in vivo.

Probiotic Bifidobacterium lactis 420 reverses diabetic status in mice under high-fat diet by reducing plasma endotoxin and tissue inflammation

R. Burcelin[1], S. Lahtinen[2], A. Waget[1], P. Klopp[1], C. Vachoux[1], K. Olli[2], D. Carcano[3], J. Amar[4], N. Rautonen[2];
[1]Functional Genomics, Inserm U858, Toulouse, France, [2], Health & Nutrition, Danisco Bioactives, kantivik, Finland, [3]Danisco Bioactives, Paris, France, [4]Department of Therapeutics, Toulouse, France.

Background and aims: It has been proposed that alterations in the intestinal microbiota may be causally involved in high-fat diet (HFD)-induced meta-

bolic diseases. Therefore, an efficient probiotic treatment should modifies the deleterious impact of the fat-enriched diet on the occurrence of diabetes.
Materials and methods: We here daily treated insulin resistant HFD mice with 10-8 to 10-10 Bifidobacterium lactis 420 daily for 6 weeks.
Results: The probiotic treatment dose dependently reduced glucose intolerance. The treatment with 109cells daily reduced the impact of HFD on body fat mass, mesenteric adipose tissue mass, fasted hyperinsulinemia, and insulin resistance as assessed by the euglycemic clamp technique. Conversely, fed insulin secretion was improved. This improved glucose metabolism was associated with a lowering of plasma LPS concentration i.e. metabolic endotoxemia. Similarly, liver and adipose tissue cytokine mRNA expression (Il6, TNFa, IL1, PAI-1) were reduced. Interestingly, we detected bacteria in the mesenteric adipose depot of HFD mice when compared with normal chow whereas the subcutaneous fat was mostly unaffected. Among these bacteria, the Enterobacteriaceae (LPS containing bacteria) were mainly increased. The probiotic treatment reduced this enrichment. We then explored that a change in intestinal epithelial cells permeability could be at the origin of the translocation of intestinal bacteria towards the adipose tissue in response to a HFD. Our data show that the probiotic extract or supernatant regulates the transepithelial electrical resistance in vitro on Caco2 cells.
Conclusion: Altogether our data suggest that Bifidobacterium lactis 420 treatment improved glucose metabolism of HFD-induced diabetic mice by reducing intestinal bacterial translocation, metabolic endotoxemia, and adipose tissue inflammation.

Discovery of a compound with potent efficacy on the activation of AMPK and treatment of type 2 diabetes
Y. Leng, S. Huang, Y. Feng, Y. Shen, Y. Hu;
Shanghai Institute of Materia Medica, Chinese Academy of Sciences, China.

Background and aims: Glucose uptake in skeletal muscle plays a key role in the maintaining glucose homeostasis. YL01 was discovered from our compound collections which could increase glucose uptake in L6 myotubes. In the present study, the *in vivo* anti-diabetic effect of YL01 was evaluated and its possible mechanisms were explored.
Materials and methods: D-2-[^{3}H]deoxyglucose uptake and [^{3}H] palmitate oxidation assay were performed to examine the effects of YL01 on the glucose uptake and free fatty acid oxidation in L6 myotubes. Activation of YL01 on the AMPK and insulin signaling pathway was investigated by western blot analysis. For *in vivo* study, YL01 was administered orally to *ob/ob* mice at the dose of 200mg/kg for 23 days. Metformin was used as positive control.
Results: YL01 dose dependently enhanced the glucose uptake and free fatty acid oxidation in L6 myotubes. Incubation of L6 myotubes with 3μM YL01 resulted in a 1.8 and 1.5 fold increase in basal glucose uptake and free fatty acid oxidation, respectively. YL01 showed no effect on Akt phosphorylation, but significantly increased AMPK and ACC phosphorylation in L6 myotubes. However, YL01 could not directly activate the recombinant AMPK kinase. The YL01 induced glucose uptake and fatty acid oxidation could be fully blocked by the pretreatment with compound C, an AMPK inhibitor. Oral administration of YL01 significantly reduced both of the non-fasting and fasting blood glucose levels and improved the impaired glucose tolerance of *ob/ob* mice. Moreover, the HbA1c levels in *ob/ob* mice also showed a decrease tendency after 23 days treatment with YL01 although it didn't reach statistic significance.
Conclusion: YL01 exerts antidiabetic effect on ob/ob mice, which suggested that it might be a therapeutic candidate for the treatment of T2DM and metabolic syndrome. Indirect activation of AMPK might be one of the possible mechanisms of this effect.

740

AT1-receptor blockade and insulin sensitivity in hypertensive subjects: the role of capillary recruitment
A.M. Jonk[1], A.J.H. Houben[1], N.C. Schaper[1], P.W. de Leeuw[1], E.H. Serné[2], Y.M. Smulders[2], C.D.A. Stehouwer[1];
[1]Dept of Internal Medicine, Maastricht University Medical Centre, Netherlands, [2]Dept of Internal Medicine, VU Medical Center, Amsterdam, Netherlands.

Background and aims: Blocking the renin-angiotensin system (RAS) improves insulin sensitivity in hypertensive subjects. However, the underlying mechanisms are undefined. An effect of insulin that is crucial for stimulating glucose uptake is the ability of insulin to regulate its own delivery, and that of glucose, to muscle cells via recruitment of the microvasculature. This study was designed to investigate the effect of acute angiotensin II AT1-receptor blockade (ARB) on insulin-mediated microvascular function and insulin-mediated glucose uptake in hypertensive subjects.
Materials and methods: A randomised, double-blind placebo-controlled trial was performed in 15 untreated mildly hypertensive subjects (BMI 26.9±2 kg/m^2; BP 150/92 mmHg), to examine the effects of acute ARB treatment (irbesartan, 600mg, oral single dose) or Ca^{2+}-blockade (felodipine, 10mg idem) as a pressor control on insulin-induced microvascular function and on insulin-mediated whole body glucose uptake (WBGU, mg/kg/min) during a hyperinsulinaemic euglycaemic clamp (50mU/kg/h). Effects of irbesartan and felodipine were compared to placebo. Skin capillary density (n/mm^2) and capillary recruitment (peak n/mm^2 during post-occlusive reactive hyperaemia, PRH) were measured with capillaroscopy. All subjects were tested on a low sodium diet (100 mmol/day).
Results: Compared to the basal state, hyperinsulinaemia increased baseline capillary density (56.8±7.1 vs. 60.2±8.3 n/mm^2, P<0.02). Relative to placebo, irbesartan, but not felodipine, increased insulin-induced capillary density (Δ cap density (median (interquartile range) +3.5 (-1.3 - +5.0) n/mm^2, P<0.02). Insulin-induced capillary recruitment was not altered by either treatment. Neither irbesartan nor felodipine enhanced WBGU.
Conclusion: Our data demonstrate that acute AT1-receptor blockade augments insulin-induced capillary density in mildly hypertensive subjects. Although glucose uptake did not increase significantly, the increased insulin-induced microvascular function found with ARB might point to improved insulin and glucose delivery as the underlying mechanism for the improved insulin sensitivity with longterm ARB treatment.

Ciliary neurotrophic factor increases plasmatic insulin half-life and improves metabolic profile in a non-insulin resistance type 2 diabetes mellitus model

G.J. Santos, C.A.M. Oliveira, E.M. Carneiro, A.C. Boschero, L.F. Rezende; Department of Anatomy, Cell Biology and Physiology and Biophysics, State University of Campinas, Brazil.

Background and aims: Type 2 diabetes mellitus (DM2) is characterized by impaired insulin sensitivity and secretion, leading to hyperglycaemia. CNTF is a cytokine that improves metabolic profile in obesity-induced and insulin resistant DM2 models, allegedly through an increase in insulin sensitivity. Besides that, CNTF promotes in vitro pancreatic islet survival. Given that, we decided to evaluate the role of functional beta cell mass maintenance by CNTF in a non-insulin resistant DM2 model. Insulin clearance is an important process that plays a role in controlling insulin action, usually evaluated as plasmatic insulin half-life. Abnormalities in this process are involved in many metabolic disorders, particularly in DM2.
Materials and methods: Neonate Swiss mice received intra-peritoneal injection of Citrate buffer (CTL), CNTF 0,1mg/Kg (CNTF), Alloxan 250mg/Kg (ALOX) or a combination of both (CNTF+ALOX). We performed an intraperitonal glucose tolerance test (ipGTT) in p26 and an intraperitonal insulin tolerance test (ipITT) in p28. Plasma glycaemia was assessed by a Roche Accu-Chek II Glucometer. Plasma insulin was assessed by Radioimmunoassay (RIA). Data are expressed as mean +/- SEM, and p<0,05.
Results: Alloxan-treated mice were hyperglycaemic and glucose intolerant, indicating that they are diabetic (DM2). Nevertheless glycaemia decrease after ipITT was similar to CTL, therefore they were not insulin resistance. CNTF+ALOX mice had lower fasting and similar fed glycaemia than CTL. Besides the glycaemia decreased after ipITT was similar to CTL. CNTF increased plasmatic insulin half-life in both CNTF and CNTF+ALOX groups (Figs.3-4), despite the fact that its impairs pancreatic islet glucose-stimulated insulin secretion.
Conclusion: The results indicate that CNTF improved metabolic profile in non-insulin resistant DM2 model, similarly to other insulin resistant models, such as obesity, suggesting that CNTF protective effects might involve mechanisms other than just increased insulin sensitivity, specially by increased plasmatic insulin half-life, and supposedly also through functional beta cell mass maintenance.

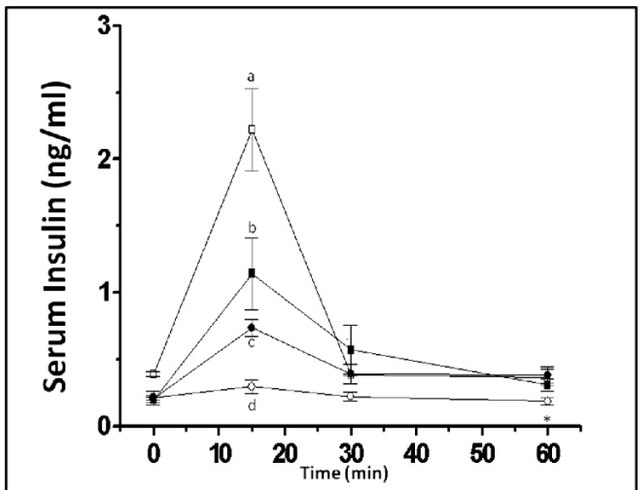

Fig.3. Serum Insulin during whole-body glucose tolerant test at p26. Blood insulin was measured from fasted mice tail at 0, 15, 30 and 60 min after intraperitoneal injection of 2 g/Kg glucose. N = 4 and *p<0,05 for difference from Control (CTL). Different letters represents statistically significant difference.

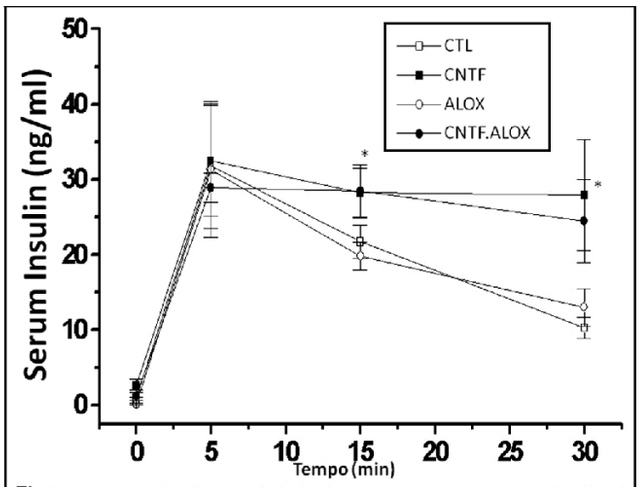

Fig.4. Serum Insulin during whole-body insulin tolerant test at p28. Blood insulin was measured from fed mice tail at 0, 5, 15 and 30 min after intraperitoneal injection of 1,75 UI/Kg insulin. N = 4 and *p<0,05 for difference from Control (CTL).

Direct effects of FGF 21 on glucose uptake in human skeletal muscle: implications for type 2 diabetes and obesity

F.L. Mashili[1], R.L. Austin[2], A.S. Deshkmukh[3], T. Fritz[4], K. Caidahl[2], K. Bergdahl[2], Z.R. Juleen[2], D.E. Moller[5], A. Kharitonenkov[5], A. Krook[1]; [1]Physiology and Pharmacology, Karolinska Institute, Stockholm, Sweden, [2]Molecular medicine and surgery, Karolinska institute, Stockholm, Sweden, [3]Molecular medicine and aurgery, Karolinska institute, Stockholm, Sweden, [4]Family medicine, Karolinska institute, Stockholm, Sweden, [5]Lilly Research Laboratories, Indianapolis, USA.

Fibroblast growth factor (FGF)-21, a novel member of the FGF family, plays a role in a variety of endocrine functions, including the regulation of glucose and lipid metabolism. We assessed serum levels of FGF-21 and skeletal muscle mRNA in normal glucose tolerant (NGT; n=40) type 2 diabetic patients (n=40). We also determined whether FGF-21 has a direct effect on glucose metabolism in cultured myotubes from NGT subjects (n=8) and adult extensor digitorum longus (EDL) skeletal muscle. Serum FGF-21 levels were increased 20% in type 2 diabetic versus NGT subjects, whereas skeletal muscle mRNA expression was unaltered. Fasting insulin, HOMA-IR, waist circumference and BMI were significantly correlated with serum fasting FGF-21 levels in type 2 diabetic, but not NGT subjects (p<0.01). Serum FGF-21 concentrations were significantly greater in the type 2 diabetic patients in the highest tertile of fasting insulin (p<0.05) and BMI (p<0.05). Stepwise regression analysis further identified BMI as the strongest independent variable that positively correlated with FGF-21 levels. FGF-21 exposure increased basal and insulin-stimulated glucose uptake in primary human myotubes, coincident with increased GLUT1 mRNA. In isolated EDL muscle, FGF-21 potentiated insulin-stimulated glucose transport, without altering phosphorylation of insulin or AMPK signaling. In conclusion plasma FGF-21 is increased in type 2 diabetic patients, and positively correlated with fasting insulin and BMI. Moreover, FGF-21 has a direct effect on skeletal muscle glucose uptake.

Characterisation of FGF19, FGF21, and FGF23 stimulated FGFR1/4 activation

M. Sommerfeld[1], K. Klein[1], C. Kleinmann[1], K. Kleinschmidt[1], S. Risch[2], O. Boscheinen[2], H.-L. Schäfer[1]; [1]BD Diabetes, Sanofi-Aventis, [2]Protein Production, Sanofi-Aventis, Frankfurt am Main, Germany.

Background and aims: The members of the FGF19-family including FGF19, FGF21, and FGF23 play a distinct role from the other FGFs based on their endocrine action and the necessity of a co-receptor. These proteins exert a wide

variety of metabolic activities like the regulation of bile acid, carbohydrate and lipid metabolism as well as phosphate, calcium and vitamin D homeostasis via binding to and activation of FGF receptors (FGFR) in presence of α-Klotho (KL) or β-Klotho (KLB). Aim of the present study was to characterize the activation of FGFR1 and FGFR4 in presence or absence of KL or KLB by FGF19, FGF21, and FGF23.

Materials and methods: The FGF induced FGFR autophosphorylation was measured via in-cell western (ICW) in CHO cells overexpressing either human FGFR1c short or long form, or FGFR4 in presence or absence of KL or KLB. ERK phosphorylation as a downstream signalling readout for FGFR activation was analysed by ICW in human primary visceral adipocytes. Time dependent *in vivo* signalling of FGF21 in WAT and liver of C57bl6/J mice was analysed using ELISA after s.c. injection of 0.6 mg/kg FGF21.

Results: We established a specific and highly sensitive ICW assay for direct analysis of the FGF induced FGFR autophosphorylation in CHO cells overexpressing different human FGFR ± KL/KLB. EC_{50} values were obtained from dose-response curves and are summarized in table 1. In these CHO cells FGF1 and FGF2 activated either FGFR1 or -4 independent of KL/KLB. FGF19 activated only FGFR4 in presence of KL or KLB. In contrast FGF21 activated the long and short form of FGFR1c efficiently only in complex with KLB. FGF21 was also able to stimulate FGFR4-KLB but was 4 times less potent than FGF19. FGF23 needed the co-receptor KL for an efficient activation of FGFR1 and -4. The analysis of ERK phosphorylation in human primary visceral adipocytes which express mainly FGFR1 and KLB demonstrated that in addition to FGF2 only FGF21 was able to activate FGFR signalling. After s.c. injection of FGF21 in mice a comparable ERK activation was found in fat tissue. No ERK activation was detectable in liver where predominantly FGFR4 is expressed. Contrary to this in WAT FGF21 stimulated a fast increase, reaching a maximum after 30-60 minutes. The decreasing signal was detectable even up to 8 hours.

Conclusion: Using cell lines overexpressing FGFR and co-receptors we could demonstrate that all members of the FGF19-family require the presence of KL or KLB for an efficient signalling through a particular FGFR isoform, e.g. FGF21 only activates FGF signalling in adipocytes that primarily express FGFR1, but not FGF19 or FGF23. We conclude that the expression of KLB and KL, in combination with particular FGFR isoforms, determines the tissue-specific metabolic activities of the FGF19-family.

Effects of short-term continuous subcutaneous insulin infusion on fasting plasma Vaspin levels in patients with new-onset type 2 diabetes mellitus

L. Ling[1,2], G. Yang[3], K. Li[3];
[1]The Key Laboratory of Laboratory Medical Diagnostics in the Ministry of Education, [2]Department of Clinical Biochemistry, [3]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Visceral adipose tissue-derived serine protease inhibitor (Vaspin) has recently been characterized as an insulin-sensitizing adopokine. However, the roles of this factor in humans remain unknown. This study was aimed to investigate the effects of short-term continuous subcutaneous insulin infusion (CSII) on plasma vaspin levels in patients with severe newly diagnosed type 2 diabetes.

Materials and methods: Thirty patients with severe newly diagnosed type 2 diabetes (T2DM), 37 subjects with impaired glucose regulation (IGT) and 38 sex-, age- and BMI-matched normal controls (NGT) participated in the study. T2DM group was treated with CSII for 2 weeks. Euglycemic-hyperinsulinemic clamps (EHC) were performed in 16 subjects of T2DM group. Plasma vaspin concentrations were measured with a commercial ELISA kit. The relationship between plasma vaspin levels and metabolic parameters was also analyzed.

Results: Fasting plasma vaspin levels were higher in T2DM than in and IGT and NGT groups (1.83+/-0.55 *vs.* 0.43+/-0.21 *vs.* 0.56 +/-0.26microg/L, $P<0.05$), but there was no difference between IGT and NGT groups. Fasting plasma vaspin concentrations were decreased significantly in T2DM group after two-week CSII treatment (1.83+/-0.55 *vs.* 1.19+/-0.57microg/L, $P<0.05$) accompany with significant amelioration of insulin sensitivity and glucose control. Changes in circulating vaspin concentrations were correlated positively with those of insulin sensitivity.

Conclusion: In T2DM patients, plasma vaspin levels are elevated, but significantly decreased after CSII treatment. These data suggest that vaspin play may a role in insulin sensitivity of diabetic humans.

Omentin, a novel visceral fat depot-specific secretory protein, enhances insulin-stimulated glucose uptake, in peripheral monocytes, in patients with type 2 diabetes

E. Maratou[1], E. Boutati[2], M. Peppa[2], V. Lambadiari[2], P. Mitrou[1], F. Spanoudi[2], G. Dimitriadis[2], S.A. Raptis[1,2];
[1]Hellenic National Diabetes Center, [2]2nd Department of Internal Medicine, Research Institute and Diabetes Center, Athens University, "Attikon" University Hospital, Greece.

Background and aims: Omentin is an adipocytokine, selectively expressed and secreted from visceral adipose tissue. Its biological action is not clear, but it is speculated that it has a beneficial effect on insulin action, since it has been shown to increase insulin signal transduction and to enhance insulin-stimulated glucose transport. Omentin plasma levels have been inversely correlated with indicators of metabolic risk, such as body mass index and HOMA. The present study investigates the effect of omentin on glucose uptake in peripheral monocytes from patients with type 2 diabetes (DM) and normoglyceamic subjects (NG).

Materials and methods: Blood (20ml) was withdrawn from 10 treatment-naive patients with type 2 diabetes (BMI 23±2kg/m^2, age 52±5years), and 8 healthy volunteers (BMI 22±2kg/m^2, age 50±6years). Circulating monocytes were incubated for 1 hour with insulin (0, 25 and 100mU/l) or/and omentin (100, 300ng/ml) to determine the abundance of GLUT4 on the plasma membrane. Cells were stained with antiGLUT4 antisera. Glucose uptake was assayed with the addition of insulin and/or omentin and the fluorescent analogue of glucose 6-NBDG and was monitored until plateau was reached. The abundance of surface GLUT4 and the glucose uptake were studied by flow cytometry. Statistical analysis of glucose uptake in response to omentin, insulin and their combination was performed by repeated-measures ANOVA. The comparison between the increments of surface GLUT4 from baseline (absence of insulin or omentin) to maximal hormonal challenge was carried out by paired t-test. Comparisons between DM and NG were performed using unpaired t-test.

Results: In monocytes from NG, insulin increased glucose uptake in a dose-dependent manner ($P<0.001$), as well as the recruitment of GLUT4 ($P<0.001$). Omentin per se, had no significant effect on either glucose uptake or GLUT4 and showed no additive effect with insulin. In DM, insulin increased glucose uptake, although to a lesser degree than in NG. In DM, omentin (300ng/ml), when added to 25 or 100uU/ml insulin, enhanced glucose uptake compared to 100uU/ml insulin ($P<0.05$ and $P<0.01$, respectively). This enhancement was supported by increments of GLUT4 (10.6±2.6% for 300ng/ml omentin +25uU/ml insulin, 15.9±4.4% for 300ng/ml omentin +100uU/ml insulin vs 7.9±2.8% for 100uU/ml insulin, $P<0.05$).

Conclusions: Omentin had no additive effect to insulin in monocytes from NG. On the other hand in DM, where insulin's action was defective, omentin enhanced insulin-stimulated glucose uptake in monocytes, partially compensating insulin's failure to produce a maximal effect.

Acute effects of estrogen receptor agonists on vascular reactivity of diabetic ovariectomised rats

G. Ozansoy, T. Akhayeva, N. Arı;
Department of Pharmacology, Ankara University, Faculty of Pharmacy, Turkey.

Background and aims: Estrogen protects against cardiovascular disease in premenopausal women. These cardioprotective effects are absent in diabetic and postmenopausal women. But the relative role of estrogen receptors (ER-alpha; ER-beta) is not clear in estrogen-induced vasorelaxation of these situations. The aim of the study was to determine how individual estrogen receptor isoforms modulate vascular reactivity in diabetic ovariectomized rats.
Materials and methods: 4 groups of Wistar rats have been used in this study. Control group (C;n=8), ovariectomized group (OVX; n=13), diabetic group (DIA;n=5), diabetic ovariectomized group (DIA+OVX; n=7). Bilateral ovariectomy had been performed to anesthetized (ketamine+xylasine) animals. Diabetes induced by a single i.v.injection of streptozotocin (45 mg/kg) a week after the operation. After 8 weeks, thorasic aortae were removed and mounted in organ baths for measuring isometric relaxations. Experiments were carried out on rings precontracted with phenylephrine (PE) to 60% of maximal contraction. Cumulative concentration-response curves for 17-beta estradiol (E2; nonselective agonist), 4,4',4"-(4-propyl-[1H]-pyrazole-1,5-triyl) tiphenol (PPT;ER-alpha selective agonist) and diarylpropionitrile (DPN;ER-beta selective agonist) were obtained with (10^{-13} - 10^{-6} M) concentration range.
Results: An increase in body weight was observed in OVX group (p<0.001 vs C group) but not in the diabetic groups. Blood glucose levels were increased in the DIA and OVX+DIA group compared with the C group (p<0.001). Plasma estradiol levels and the ratio of uterine weight/body weight were reduced in OVX,DIA and OVX+DIA group compared C group respectively (p<0.01;p<0.001) The vasorelaxation responses to estrogenic agonists E2 and PPT were reduced in OVX, DIA and OVX+DIA however these responses to DPN were reduced both OVX groups (p<0.001).The ratios % of the maximum relaxations with E2, PPT and DPN of PE-precontracted aortic rings were shown in Table(***p<0.001 vs C).
Conclusion: These findings suggest that ER-alpha has still play a vital role in diabetes or ovariectomized vessels. This study also support that the estrogenic vasodilatation is abolished under diabetic ovariectomized condition which may be contribute to diabetic postmenopausal vascular dysfunction.

The % of the maximum relaxations with E2, PPT and DPN of PE-precontracted aortic rings

Differential role of testosterone and estradiol on glucose and lipid metabolism in human skeletal muscle cells

F. Salehzadeh, L. Al-Khalili;
Molecular medicine and surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Testosterone and estradiol ratio differs between sexes, where changes in sex hormones homeostasis may cause different pathological response. We have previously shown that human skeletal muscle cell culture obtained from elderly female and male healthy subjects showed no intrinsic sex differences on glucose and lipid metabolism. Aim of the study is to determine whether testosterone or estradiol treatment have different role on lipid and glucose metabolism in human skeletal muscle cell culture.
Materials and methods: Myotubes obtained from women and men donors were treated with 10 nM testosterone or estradiol for 4 days. Insulin-stimulated glycogen synthesis and palmitate oxidation were assessed and samples were collected for immunoblot analysis to assess AMPK, AKT, ERK1/2 and p38 MAPK phosphorylation and total protein. mRNA levels of different metabolic genes were also determined using real-time PCR analysis.
Results: Testosterone enhanced glucose incorporation to glycogen and insulin-stimulated Akt phosphorylation specifically in myotubes from women, but not from men, donors, indicating sex specific role of testosterone on glycogen synthesis in skeletal muscle. Testosterone enhanced both AMPK phosphorylation and lipid oxidation in myotubes obtained from both sexes. mRNA expression showed a differential response to either sex hormone treatment with no sex differences. Testosterone increased the glycogen synthase 1 (GYS1), while estradiol altered the mRNA expression of stearoyl-CoA desaturase (SCD) and Pyruvate dehydrogenase kinase 4 (PDK4).
Conclusion: Only testosterone treatment showed an effect on lipid metabolism while, both sex hormones changed the mRNA expression of some genes involved in lipid oxidation. In this study, we are able to suggest an important role of testosterone on glucose and lipid metabolism in human skeletal muscle cells, with no clear effect of estradiol on metabolism and there is a sexual difference on cellular metabolism with sex hormones treatment.

Circulating pigment epithelium-derived factor levels are associated with insulin resistance and decrease after weight loss

M. Sabater[1], J.M. Moreno-Navarrete[1], F.J. Ortega[1], G. Pardo[1], W. Ricart[1], G. Frühbeck[2], J.M. Fernández-Real[1];
[1]Department of Diabetes, Endocrinology and Nutrition, Institut d'Investigació Biomèdica de Girona, [2]Department of Endocrinology and Metabolic Research Laboratory, Clínica Universitaria, University of Navarra, Pamplona, Spain.

Background and aims: Pigment Epithelium-Derived factor (PEDF) is a 50-kDa protein with anti-inflammatory activity. We aimed to study PEDF in vivo in association with insulin resistance and in vitro in human adipocytes.
Materials and methods: Circulating PEDF (ELISA) and metabolic profile were assessed in 125 Caucasian men. PEDF levels were also assessed in an independent cohort of subjects (n=33) to study the effects of changing insulin action. PEDF gene expression and PEDF secretion were also measured during differentiation of human preadipocytes.
Results: In all subjects, PEDF were positively associated with BMI (r=0.326, p<0.0001), waist-to-hip ratio (r=0.380, p<0.0001), glycated hemoglobin and fasting triglycerides; and negatively with insulin sensitivity (r=-0.320, p<0.0001). Circulating PEDF levels was significantly increased in subjects

with altered glucose tolerance and type 2 diabetes. Of the inflammatory markers measured, circulating PEDF levels were positively associated with serum sTNFR1 and IL-10 in obese subjects. Interestingly, weight loss led to significantly decreased of PEDF concentration from 34.8±19.3 μg/ml to 22.5±14.2 μg/ml (p<0.0001). Multiple linear regression analyses revealed that insulin sensitivity contributed independently to explain 14% of the variance in circulating PEDF levels, after controlling for the effects of BMI, age, and log fasting triglycerides. Differences in circulating total PEDF observed after weight loss were strongly related to changes in obesity and insulin resistance measures. *PEDF* gene expression and PEDF secretion increased during differentiation of human pre-adipocytes.
Conclusion: Circulating PEDF is strongly associated with insulin sensitivity. The findings show, for the first time in humans, that circulating PEDF concentrations decrease significantly after weight loss in association with improvement of insulin action. PEDF seems to be involved in human adipocyte biology.

Osteocalcin and its effect on metabolic control in type 1 diabetes
N. Napoli[1], C. Bizzarri[2], D. Pitocco[3], C. Suraci[4], M. Altomare[4], E. Sacchetti[1], L. Valente[1], P. Pozzilli[1];
[1]Campus Bio-Medico di Roma, [2]Unit of Endocrinology and Diabetes, Bambino Gesù Children's Hospital, [3]Universita' Cattolica del Sacro Cuore, [4]Ospedale Sandro Pertini, Roma, Italy.

Background and aims: Osteocalcin (OC), produced by osteoblasts, is considered a predictor of fractures and its elevated levels are associated with both high bone formation and turnover. Recent animal studies have shown that OC acts also as a hormone regulating glucose metabolism and fat mass. Few studies have explored this relationship in humans showing an inverse correlation with fasting plasma glucose, HbA1c and fat mass in type 2 diabetic patients. However, no data are available in type 1 diabetes (T1D). Aim of this study was to investigate the relationship between OC, HbA1c and fasting serum C-peptide in patients with recent onset T1D. Moreover, we tested in T1D patients the effect of 1 year calcitriol administration on OC, residual β-cell function and metabolic control (HbA1c and insulin requirement).
Material and methods: 34 subjects (mean age 22.2±1.7 SE) with recent-onset T1D and baseline C-peptide > 0.25 nM were enrolled in this study. Intensive insulin therapy was implemented with three daily injections of regular insulin + bedtime insulin in these patients. Osteocalcin was analyzed at the time of diagnosis and one year after treatment with either 0.25 μg daily calcitriol or placebo. OC was evaluated by ECLIA method (modular E170, Roche Diagnostics, Mannheim, Germany) in relation to C-peptide.
Results: At *T1D diagnosis*, OC levels were significantly lower in female than in male patients (17.8±3.1 ng/mL vs 43.9±6.9 ng/mL; p<0.01) while no other metabolic parameters as HBA1c, C-peptide differed between gender. Analyzing the whole group of patients, OC levels were positively associated with insulin requirement (r=0.48, P<0.01), while no significant correlation were found in relation to HbA1c and C-peptide. *At 1 year follow-up,* OC levels were increased (11%) in the placebo group while dropped by 25% in the calcitriol group, but their levels were not significantly different compared to diagnosis due to high variability. No significant differences were observed between calcitriol and placebo groups for OC (37.2±11.8 ng/mL vs 25.8±7.4 ng/mL; p=NS), C-peptide(1.05±0.25 nM vs 25.8±7.4 nM; p=NS), HbA1c (6.8±1.13% vs 7.14±1.1%; p=NS) and insulin requirement (0.48±0.2 vs 0.58±0.21; p=NS).
Conclusion: In contrast to what expected, OC was not associated with residual pancreatic β-cell function or metabolic control in recently diagnosed T1D patients. Calcitriol had no effect on residual β function, insulin dose or the overall metabolic control. Further studies with a larger group of patients are needed to confirm these data.

The relationship between vitamin D status and markers of oxidation and inflammation in subjcets with the metabolic syndrome
K.I. Birkeland[1], H.L. Gulseth[1], I.M.F. Gjelstad[1,2], J.A. Lovegrove[3], C. Defoort[4], E.E. Blaak[5], J. Lopez-Miranda[6], A. Dembinska-Kiec[7], U. Risérus[8], H.M. Roche[9], C.A. Drevon[2];
[1]Department of Endocrinology, Oslo University Hospital Aker, Norway, [2]Department of Nutrition, University of Oslo, Norway, [3]University of Reading, Reading, United Kingdom, [4]Department of Endocrinology, INSERM, Marseille, France, [5]NUTRIM, Maastricht University, Netherlands, [6]University of Cordoba, Spain, [7]Jagiellonian Medical College, Krakow, Poland, [8]Uppsala University, Sweden, [9]University College Dublin, Ireland.

Background and aims: Low levels of vitamin D may increase the risk of developing type 2 diabetes, and inflammation and oxidative stress may participate in the pathogenesis of diabetes. We have evaluated the relationship between serum 25-hydroxyvitamin D_3 ($25(OH)D_3$) and markers of inflammation and oxidative stress in subjects with the metabolic syndrome (MetS).
Material and methods: $25(OH)D_3$ was measured with HPLC-MS in subjects with the MetS in the LIPGENE dietary intervention study. CRP was measured by ELISA and urinary 8-iso-prostaglandin $F_{2\alpha}$ (8-iso-$PGF_{2\alpha}$) and 15-keto-dihydro-prostaglandin $F_{2\alpha}$ (15-keto $PGF_{2\alpha}$) were determined by RIA and adjusted for urinary creatinine. Subjects (n = 446, 45% males) were from eight European centres. Mean (SD) age was 54.7 (9.0) years and BMI 32.3 (4.1) kg/m^2.
Results: The mean (SD) concentration of $25(OH)D_3$ was 57.1 (26.0) nmol/L. Subjects were grouped according to their vitamin D status; severely deficient (<25 nmol/L, n=20), deficient (25-49.9 nmol/L, n=189), insufficient (50-74.9 nmol/L, n=146) and sufficient (> 75nmol/L, n=91). Markers of oxidative stress (8-iso-$PGF_{2\alpha}$ p=0.022) and inflammation (15-keto $PGF_{2\alpha}$, p=0.022 and CRP, p=0.05) differed significantly across categories of $25(OH)D_3$. Plasma concentrations of $25(OH)D_3$ were significantly negatively associated with BMI (r=-0.23, p<0.001), CRP (r=-0.11, p=0.02) and 15-keto $PGF_{2\alpha}$ (r=-0.10, p=0.039), but not with 8-iso-$PGF_{2\alpha}$ (r=-0.08, p=0.09).
Conclusion: In a large sample of subjects with the metabolic syndrome low plasma concentrations of $25(OH)D_3$ were associated with enhanced markers of inflammation and oxidative stress.

Arab herbal medicine-based combination of four anti-diabetes plants stabilises a physiological blood glucose level

H. Zaid, O. Saed, B. Saad;
Qasemi Research Center, Al-Qasemi Academic College, Baqa El-Gharbia, Israel.

Background and aims: Medicinal plant-based drug discovery provides important leads against various pharmacological targets including diabetes, which represents a worldwide predominant public health concern. Several drugs are used to treat this disease. Based on our traditional knowledge, *Juglans regia* L., *Olea europea* L., *Urtica dioica* L., and *Atriplex halimus.* L. exhibit favorable effects on blood glucose levels. This study was aimed at investigating safety and efficacy of a fixed mixture of these plants.
Materials and methods: In the present study we assessed safety and anti-diabetic effects of the combination of the four plants leave extracts using *in vivo* (human type2 diabetic volunteers and Streptozotocin-induced diabetic rats) and *in vitro* test systems (human fibroblasts and skeletal muscle cells treated with increasing concentrations of Plant mixture).
Results: No sign of toxic effects were seen in cultured human fibroblasts and skeletal muscle cells treated with increasing concentrations of Plant mixture. Anti-diabetic effects were evidenced by inhibition of glucose intestinal absorption (~49%) in a rat gut-segment. Furthermore, treatment with these plant combined extracts of Streptozotocin-induced diabetic rats for 2-3 weeks, showed a significant reduction in glucose levels [above 400±50 mg/dl to 210±22 mg/dl (P<0.001)] and significantly improved sugar uptake during the glucose tolerance test, compared with positive control. In addition, glucose levels were tested in sixteen human volunteers, with the recent onset of type 2 diabetes mellitus, who received the plants mixture tablets 1X3 daily for a period of 4 weeks. Within the first week of the tablets consumption, baseline glucose levels were significantly reduced from 290±40 to 210±20 mg/dl. At baseline, a subgroup of eleven of these subjects had glucose levels below 300mg/dl and the other subgroup had levels ≥300 mg/dl. Clinically acceptable glucose levels were achieved during the 2-3 weeks of therapy in the former subgroup and during the 4th week of therapy in the latter subgroup. No side effect was reported.
Conclusion: Results demonstrate safety, tolerability and efficacy of herbal combinations of four plants that seem to act differently but synergistically to regulate glucose-homeostasis.

752

Effects of Mongolian traditional medicinal plant extract of Gentianaceae on *in vivo* insulin action in streptozotocin-induced diabetic rats

O. Khookhor, Y. Sato;
Department of Health Science, Aichi Gakuin University, Nagoya, Japan.

Background and aims: Lomatogonuim rotatum (L) Fries ex Fern and Gentiana acuta Michaux of the family Gentianaceae have been documented as traditional plant treatments for liver diseases.We firstly performed a preliminary investigated on the acute effect of Mongolian medicinal plant extracts Lomatogonuim rotatum and Gentiana acuta , Gentianaceae on the blood glucose tolerance in rats, evaluated by an oral glucose tolerance test (OGTT). Then, investigated the effects of the same extracts on in vivo insulin action in streptozotocin (50mg.kg-1BW,i.v.)-induced diabetic rats by means of the euglycemic clamp.
Materials and methods: Plant materials were provided by the Institute of Chemistry and Chemical-technology of MAS (Mongolia). Air-dried plant materials were extracted with 10 volumes of hot water (80C), filtered, lyophilized, and stored at 40C. Male Wistar rats aged 8 weeks (220-240g bw).Oral glucose tolerance test (OGTT). Time-course blood glucose concentrations were determined 30, 60, and 120 min after glucose load. Whole blood and plasma assays. Blood glucose concentration was determined using an automated analyzer model 2300 STAT Plus. Plasma insulin concentration was measured by the Special Reference Laboratories Inc. using a chemiluminescence enzyme immunoassay method. Statistical analysis: Data were analyzed by one-way analysis of variance. When a significant difference was found ($P < 0.05$), values were further compared with the Student's t test. The Stat View was used for statistical analyses. Data are expressed as means ± SE.
Results: 1.Effect of plant extract on blood glucose concentrations. Blood glucose concentrations and net incremental area under the curve (net AUC) for control and plant extracts before and after oral load of glucose are summarized. Compared to the control group, plant extract groups (30min) had significantly lower peak blood glucose concentrations during the OGTT with Lomatogonium rotatum and Gentiana acuta, Gentianaceae. 2. Effect of 7 days administration of plant extracts on MCR Rats divided into control and 7-days oral administration groups. At low-dose insulin infusion, the decreased metabolic clearance rates of glucose (MCR) in diabetic rats were improved by a 7 days administration of plant extracts (500mg.kg.BW, p.o.; 7 days effect: non-diabetic control: 15.2± 0.8 ml kg-1min-1, diabetic control: 7.6± 0.7ml kg-1min-1. versus plant extract 1: 14.1 ± 1.4 ml kg-1min-1, and versus plant extract 2: 13.2 ± 1.2 ml kg-1min-1, P<0.001, respectively).
Conclusion: These results suggest that a 7 days administration of the Mongolian plant extracts Gentianaceae can improve glucose utilization and insulin resistance in diabetic rats.

Chronic caffeine intake reverses age induced-insulin resistance in the rat

S.V. Conde[1], E.C. Monteiro[1], M. Mota-Carmo[2], M.P. Guarino[2];
[1]Pharmacology, [2]Pathophysilogy, CEDOC, Faculty of Medical Sciences, Lisboa, Portugal.

Background and aims: Aging is known to be associated with increasing insulin resistance and declining glucose tolerance. Insulin resistance is one of the core metabolic abnormalities in type 2 diabetes and metabolic syndrome. One of the lifestyle changes advised in these diseases is coffee withdrawal, based on several studies describing that caffeine can acutely lower insulin sensitivity. However the benefits of coffee withdrawal have been questioned by several studies that suggest no association between long-term coffee consumption and diabetes which seems to indicate that acute and chronic intake have opposite effects. In the present work we tested the hypothesis that chronic caffeine intake reverses age induced-insulin resistance in the rat and investigated if the mechanism by which caffeine restores insulin sensitivity is due to a decrease in visceral fat or oxidative stress.
Materials and methods: Six groups of rats were used: 3 months old (control), 3 months caffeine-treated, 12 months old, 12 months caffeine-treated, 24 months old and 24 months caffeine-treated. Caffeine was administered in drinking water (1g/l) during 15 days. Insulin sensitivity was assessed by means of an insulin tolerance test. Blood pressure, weight, visceral and total fat, basal glycemia, insulinemia and plasma total antioxidant capacity were also measured.
Results: Insulin sensitivity diminished in 12 and 24 months rats as the constant of the insulin tolerance test (K_{ITT}) decreased significantly to 2.77±0.17 and 2.47±0.18 compared to the control value 4.69±0.42 (3 months rats). Chronic caffeine intake restored insulin sensitivity to control values both in 12 and 24 months rats. Basal glycemia was 100.53±4.32 mg/dL, 96.87±3.43 mg/dL and 96.63±3.10 mg/dL in 3, 12 and 24 months rats. Caffeine did not modify basal glycemia in any of the groups tested. Both 12 and 24 months rats were hyperinsulinemic, as insulin levels increased significantly by 169 and 160%, respectively from a control value of 2.05±0.4 µg/L. Chronic caffeine intake significantly decreased plasma insulin levels ($p<0.5$) both in 12 and 24 months rats, although without restoring plasma insulin to control values. Visceral and total fat were significantly increased both in 12 and 24 months rats when compared with 3 month rats, however no correlations were found between visceral fat and the K_{ITT} in both 12 and 24 months rats ($p=0.06$ and $r=0.88$; $p = 0.77$ and $r= 0.13$, respectively). Caffeine intake significantly decreased visceral and total fat in 12 but not in 24 months rats. Also, no correlations were found between visceral fat and the K_{ITT} in 12 and 24 months old caffeine treated rats ($p=-0.35$ and $r=0.35$; $p = 0.57$ and $r= 0.24$, respectively). Additionally, chronic caffeine intake did not significantly modify the weight of the animals within the groups. Total antioxidant capacity (TAC) was decreased in 12 and 24 months rats. Caffeine intake did not modify significantly TAC in any of the groups tested.
Conclusion: Chronic caffeine intake reverses age induced-insulin resistance in rats, an effect that were independent of weight loss, visceral fat and oxidative stress.

Shikonin improves blood glucose levels in diabetic GK rats and increases glucose uptake in adipocyte and muscle cells, independent of its effect on NADPH oxidase

K. Yassin[1], A. Öberg[2], R.I. Csikasz[2], I.G. Shabalina[2], M. Wilcke[3], C.-G. Östenson[1], T. Bengtsson[2];
[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, [2]Department of Physiology, Arrhenius Laboratories, The Wenner-Gren Institute, Stockholm University, [3]Glucox Biotech AB, Stockholm, Sweden.

Background and aims: Shikonin is a naphtoquinone derivative from the Chinese plant *Lithospermum erythrorhizon*. It has been reported to inhibit the formation of the NADPH oxidase, an enzyme complex that catalyses the formation of highly reactive superoxide anions. Shikonin has been shown to stimulate glucose-uptake, and potentiate insulin-induced glucose-uptake in 3T3-L1 adipocytes. The diabetic state is associated with excess superoxide production that may contribute to failure of insulin to stimulate glucose uptake in fat and muscle. Hence, our aim was to investigate the effect of shikonin, administered intraperitoneally (i.p.), on blood glucose levels and insulin sensitivity in the spontaneously diabetic Goto-Kakizaki (GK) rats. Having found that shikonin improved glucose homeostasis in GK rats, we further studied its mechanism of action in vitro.
Materials and methods: Shikonin was given i.p. to GK rats (n=6) once daily (10 mg/kg) for 4 days and compared with placebo (vehicle DMSO/oil (9:1)) injected i.p. during 4 days in the same animals. Plasma glucose (PG) levels were measured daily before and 6h after i.p. injections. At the 4th day, an insulin sensitivity test was performed, where glucose responses were measured after s.c. injection of 0.5 U/kg insulin. L6 muscle cells and 3T3-L1 cells were used as model systems to study how shikonin regulates glucose uptake. Glucose uptake was measured using the 2-deoxy-[^{3}H]-D-glucose method. AMPK and Akt phosphorylation were determined by Western blot. Oxygen consumption was monitored with a Clark-type oxygen electrode.
Results: Shikonin significantly lowered morning PG on 2^{nd,} 3rd and 4th days compared to day 1 ($p < 0.01$ for all days compared to the first day); the total area under the glucose curve was lower in shikonin treated rats vs control rats (p= 0.014). In the insulin sensitivity test, PG levels were more reduced in the shikonin treated rats; 30-240 min after injection of insulin, the areas under the PG curves (AUCs) being 39.3±105.9 and 536.4 ±144.0 mM/210 min, respectively ($p<0.02$). Shikonin increased basal and insulin-stimulated glucose uptake in L6 cells and 3T3-L1, which does not express all subunits of NADPH oxidase. Shikonin did not mimic the effect of AMPK activator AICAR on AMPK-phosphorylation, i.e. AMPK was not phosphorylated by shikonin. Furthermore, shikonin did not induce any change in AMP-to-ATP ratio and Akt phosphorylation in L6 cell lines, nor did it increase oxygen consumption in skeletal muscle mitochondria. However the cell-permeable calcium chelator, BAPTA-AM (5 μM), blocked shikonin-stimulated glucose uptake in L6 cell lines.
Conclusion: We conclude that shikonin treatment in GK rats decreases PG levels and improve insulin sensitivity. Since shikonin increased glucose uptake in cell lines devoid of NADPH oxidase, this enzyme cannot be involved in shikonin-mediated effects on glucose metabolism. Our present findings suggest that shikonin exerts its effect on glucose uptake by a calcium related pathway.

Effect of resveratrol on insulin sensitivity, oxidative stress and Akt pathway in humans

P. Brasnyó[1], G.A. Molnár[1], M. Mohás[1], L. Markó[1], B. Laczy[1], J. Cseh[1], E. Mikolás[1], I.A. Szijártó[1], Á. Mérei[1], R. Halmai[1], L.G. Mészáros[2], B. Sümegi[3], I. Wittmann[1];
[1]Second Department of Medicine and Nephrological Center, University of Pécs, Medical Faculty, Hungary, [2]Life Sciences Foundation Theoretical Biochemistry Group, Augusta, USA, [3]Department of Biochemistry and Medical Chemistry, University of Pécs, Medical Faculty, Hungary.
Background and aims: To examine whether the red wine polyphenol, resveratrol, improves insulin sensitivity in type 2 diabetic patients, and to gain insight into the mechanism of its action.

Materials and methods: After an initial general examination (including blood chemistry), 19 patients enrolled in the 4-week long study were randomly assigned into two groups: a resveratrol group receiving oral 2 x 5 mg resveratrol and a respective control group receiving placebo. Before, after two weeks and at the end of the trial insulin resistance/sensitivity, creatinine-normalized ortho-tyrosine level in urine samples (as a measure of oxidative stress), incretin levels and pAkt/Akt ratio in platelets were assessed and statistically analyzed.
Results: After 4 weeks, resveratrol significantly decreased insulin resistance (HOMAIR) and urinary ortho-tyrosine excretion, while it increased pAkt/Akt levels in platelets. On the other hand, it had no effect on parameters characterizing beta cell function.
Conclusion: This study shows the first time that resveratrol improves insulin sensitivity in humans, which might be due to a resveratrol-induced decrease in oxidative stress that leads to a more efficient insulin signaling via the Akt pathway.

PS 66 Liver, hepatic steatosis and metabolism

756

An analysis of liver enzymes in type 1 and type 2 diabetes and their associations with glycaemic status independent of total adiposity

N. Sattar, Scottish Diabetes Research Network Epidemiology Group, The Scottish-Southampton Diabetes and Liver Disease Collaboration; BHF Glasgow Cardiovascular Research Centre, University of Glasgow, United Kingdom.

Background and aims: Robust evidence indicates hepatic fat and related liver enzymes, alanine transaminase [ALT] and gamma glutamyl transferase [GGT], predict type 2 diabetes. However, the association of these enzymes with glycaemic control in people with diabetes is less well studied. We therefore investigated whether there is an association between liver enzymes and glycaemic control independently of age, sex, adiposity and smoking status in type 1 and type 2 diabetes
Materials and methods: We used population-based diabetes register data for 2008 linked to laboratory data for 3862 people with type 1 and 25075 people with type 2 diabetes in south-east Scotland. Regression analyses were used to examine associations between ALT or GGT and HbA1c in people with type 1 and type 2 diabetes controlling for age, sex, current smoking status and body mass index (BMI); after excluding people with ALT and GGT values more than twice the upper limit of normal (>2ULN) and people with HbA1c>10% (associations were not linear beyond these values). Data on alcohol intake were not available.
Results: Data were available for ALT and GGT on 27258 (94%) and 25840 (89%) people respectively. There were 1447 people (5.3%) whose ALT was >2ULN (>100U/l), 4662 people (18.0%) whose GGT was >2ULN (>110U/l) and 1972 (6.9%) people whose HbA1c was >10% leaving data available for analysis for 2416 people with type 1 and 19058 people with type 2 diabetes. ALT was 9.9 U/l higher ($p<0.0001$) and GGT was 10.5 U/l higher ($p<0.0001$) in people with type 2 compared to type 1 diabetes after adjustment as described above. BMI≥30kg/m2 was associated with higher levels of ALT (2.63 U/l, $p<0.001$) and GGT (4.65U/l, $p<0.001$) when compared to BMI<30kg/m2. Current smoking compared to non-current smoking status was associated with lower ALT levels (by 1.84 U/l, $p<0.001$) and higher GGT levels (by 1.94 U/l, $p<0.001$). In fully adjusted analyses, each 1% increase in HbA1c was associated with: a) no significant change in ALT in type 1 diabetes but a 0.90 U/l increase in type 2 diabetes ($p<0.0001$); and b) a 0.73 U/l increase in GGT ($p=0.04$) in type 1 diabetes, and a 1.23U/l ($p<0.0001$) increase in type 2. There was a significant ($p<0.001$) interaction between obesity (BMI≥30kg/m2) and GGT with HbA1c as the outcome for people with type 2 diabetes in adjusted analyses
Conclusion: The relationship between glycaemic control and either ALT or GGT differs by diabetes type. The data provide strong, albeit indirect, evidence for an influence of hepatic fat accumulation (independent of total adiposity) on glycaemic control in type 2 diabetes. Further work is required to establish the role of alcohol consumption and diabetes drugs on such patterns and to investigate whether improved glycaemic control results in reduction of liver enzymes and / or vice versa.

757

Serum interleukin 1 receptor antagonist level is independently associated with nonalcoholic steatohepatitis in humans

J.A. Pihlajamäki[1], M. Simonen[1], T. Kuulasmaa[1], V. Kärjä[2], S. Gronlund[3], P. Kakela[3], M. Paakkonen[3], K. Punnonen[4], H. Gylling[5], J. Kuusisto[1], M. Laakso[1];
[1]Department of Medicine, [2]Department of Pathology, [3]Department of Surgery, [4]ISLAB, [5]Department of Clinical Nutrition, University of Eastern Finland, Kuopio, Finland.

Background and aims: Mechanisms leading to non-alcoholic steatohepatitis (NASH) have remained unclear, and noninvasive diagnosis of NASH is challenging. In this study we aimed to identify novel serum markers for NASH.
Materials and methods: In a cross-sectional population-based cohort of 6447 men (58±7 years, BMI 27.0±3.9 kg/m2) the association of serum ALT levels with glucose tolerance, Matsuda insulin sensitivity index (ISI), serum lipids and lipoproteins, and serum levels of adiponectin and cytokines were investigated. Liver biopsies from 60 morbidly obese individuals (44.2±8.3 years, BMI 45.5±6.1 kg/m2) were used for histological assessment. Gene expression of IL1RN in liver, subcutaneous fat and visceral fat was investigated.
Results: The strongest determinants of ALT levels were Matsuda ISI and serum IL-1RA levels in the population study. IL-1RA levels associated significantly with ALT levels even after adjusting for BMI, alcohol consumption and insulin sensitivity (general linear model, p=2x10-21). In morbidly obese subjects serum levels of IL-1RA also associated with the degree of lobular inflammation in liver histology ($p=0.034$). Furthermore, serum IL-1RA levels decreased after obesity surgery ($r=0.443$, $p=0.024$) and this decrease correlated with the change in histologically assessed lobular inflammation ($r=0.662$, $p=0.027$). Finally, expression of IL1RN in liver and visceral fat correlated positively with serum IL-1RA levels and liver steatosis ($r=0.352$ and 0.462, respectively, $p<0.05$).
Conclusion: IL-1RA serum levels correlate with serum ALT independent of obesity, alcohol consumption and insulin resistance, most likely reflecting an association between serum IL-1RA and NASH.

Increased intramyocellular lipid but normal intrahepatocellular lipid content characterises polycystic ovary syndrome compared with age- and BMI-matched healthy controls

H. Jones[1], V.S. Sprung[1], C.J. Pugh[1], A. Irwin[2], N. Aziz[3], G.J. Kemp[4], V.L. Adams[4], W.E. Bimson[4], D.J. Cuthbertson[2];
[1]Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, [2]Department of Diabetes and Endocrinology, University Hospital Aintree, [3]Department of Gynaecology, Liverpool Women's Hospital, [4]Magnetic Resonance and Image Analysis Research Centre (MARIARC), University of Liverpool, United Kingdom.

Background and aims: It has been suggested that there is a high prevalence of non-alcoholic fatty liver disease (NAFLD) in women with Polycystic Ovary Syndrome (PCOS) as both are associated with obesity and insulin resistance (IR). Furthermore, the mechanism for the peripheral insulin resistance observed in PCOS remains unclear. The aim of this study was to determine whether PCOS women have higher liver fat (intrahepatocellular lipid, IHCL) or skeletal muscle fat (intramyocellular lipid, IMCL), compared with age- and body mass index-matched controls, and to determine whether higher tissue fat content may explain IR.
Materials and methods: 20 PCOS women and 9 healthy controls were recruited. Fasting glucose, lipids, AST and ALT were measured and all subjects underwent whole body magnetic resonance imaging with proton magnetic resonance spectroscopy to determine IHCL and IMCL (soleus, SOL and tibialis anterior, TA) levels.
Results: PCOS women and healthy controls were similar with respect to BMI and age (32 ± 8 vs. 28 ± 5 kg/m$^{2;}$ 26 ± 4y vs. 28 ± 7y). PCOS women had higher fasting triglycerides but similar liver transaminases and similar IHCL (8 ± 13% vs. 3 ± 4%; $p=0.09$). IHCL was significantly correlated with BMI and waist:hip ratio (WHR) in PCOS and control women. At any given BMI or WHR, PCOS women and control women had similar IHCL. IHCL was related to serum triglycerides. There was also a close correlation between IMCL and BMI. IMCL content was greater in the TA muscle in PCOS vs. control (77 ± 56% vs. 41 ± 30%; $p<0.05$) but not in soleus (54 ± 38% vs. 34±24; $p=0.1$).
Conclusion: Despite the reported high prevalence of NAFLD in PCOS we found that IHCL was elevated similarly in proportion to the BMI in both PCOS and healthy controls unlike IMCL which was higher in women with PCOS and may potentially explain peripheral insulin resistance.

Proteasome dysfunction contributes to endoplasmic reticulum stress and insulin resistance in type 2 diabetic liver

T. Otoda[1], H. Misu[1], S. Kurita[1], M. Yamamoto[2], T. Ota[3], K.R. Shima[1], S. Iseki[2], S. Murata[4], K. Tanaka[5], S. Kaneko[1], T. Takamura[1];
[1]Disease Control and Homeostasis, Kanazawa University Graduate School of Medical Science, [2]Histology and Embryology, Kanazawa University Graduate School of Medical Science, [3]Frontier Science Organization, Kanazawa University, [4]Laboratory of Protein Metabolism, Department of Integrated Biology, Graduate School of Pharmaceutica, The University of Tokyo, [5]Laboratory of Frontier Science, Tokyo Metropolitan Institute of Medical Science, Japan.

Background and aims: Insulin resistance is a key feature of people with type 2 diabetes (T2D). Growing evidence has suggested that accumulation

of endoplasmic reticulum (ER) stress in liver is a major contributor to insulin resistance; however, the molecular mechanisms linking diabetes and ER stress are not fully understood. We have previously reported that the hepatic expression of genes involved in proteasomal degradation pathway are coordinately up-regulated in people with obesity and T2D (Obesity 2008). Specifically, the expression levels of proteasome activator (PA) 28-α subunit gene was significantly higher in people with obesity than in non-obese individuals. The proteasome is an important multicatalytic enzyme complex that degrades misfolded and oxidized proteins, signal transduction factors, and antigenic peptides for presentation. Indeed, NEFA or oxidative stress have been reported to induce proteasome dysregulation in hepatocyte. The aim of this study is to clarify the role of proteasome function for insulin resistance in obesity and T2D using PA 28α, β, and γ triple knockout (KO) mice.

Materials and methods: We assessed the metabolic phenotype of PA28αβγ KO mice. After sacrifice, blood sample, liver and femoris muscle were collected and proteasome activity was measured by the chymotrypsin-like protease activity. Livers were observed by electron microscope. Gene and protein expression of markers associated with ER stress was analyzed by realtime-PCR and Western blot.

Results: 1) Proteasome activity was inhibited in livers of both genetically diabetic db/db mice and C57BL/6 mice fed a high-fat diet (HFD) ($p<0.05$; $p=0.083$, $n=4$), whereas gene expression levels involved in proteasomal degradation pathway were up-regulated in livers of mice fed a HFD. 2) Proteasome activity in livers of PA28αβγ KO mice was inhibited by 35% compared with control mice ($p=0.05$, $n=3$). 3) PA28αβγ KO mice showed glucose intorelance in glucose loading test. 4) Insulin-stimulated phosphorylation of Akt was impaired in livers of PA28αβγ KO mice, but not in skeletal muscle. 5) Western blot analysis displayed an accumulation of polyubiquited proteins in the liver of PA28αβγ KO mice. 6) Electron microscopic examination detects a massive expansion of endoplasmic reticulum and double-membrane and multilamellar structures of large autophagosomes in hepatocytes from PA28αβγ KO mice. 7) CHOP and spliced XBP-1 mRNA level were increased in livers from PA28αβγ KO mice ($p<0.05$; $p=0.077$, $n=3$-5). 8) GRP78, pPERK, peIF2α, pIRE-1, CHOP, and pJNK protein levels were up-regulated in livers obtained from PA28αβγ KO mice ($p<0.05$, $n=5$).

Conclusion: Proteasome dysfunction induces ER stress and subsequent insulin resistance in the liver with obesity and T2D. Our study demonstrates a previously unrecognized role of ubiquitin-proteasome pathway for the development of insulin resistance in the liver and suggests that this pathway is a novel target for the treatment of T2D.

Berberine reduces hepatic fat content in SD rats with a high-fat diet by increasing hepatic MTTP function

X. Chang[1], X. Gao[1], M. Liu[1], H. Yan[1], Y. Liu[2], Q. Wang[2];
[1]Endocrinology & Metabolism, Zhongshan Hospital, [2]Laboratory of Inflammation, Cellular Stress and Metabolic Regulation, The Institute for nutritional science, Shanghai, China.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is closely associated with obesity, insulin resistance, and type 2 diabetes. Hepatic fat content plays a key role in these disorders, so reducing hepatic fat accumulation can be an effective strategy to prevent type 2 diabetes. In our previous study, we found that berberine (BBR) can reduce hepatic triglyceride content and decline the DNA methylation level of hepatic microsomal triglyceride transfer protein (MTTP) promoter to upregulate MTTP expression. MTTP is necessary for the assembly and secretion of apoB-containing lipoproteins (e.g.VLDL, LDL), whereby lipids are normally exported from the liver. Hypermethylation of MTTP promoter reversed by BBR treatment, but it is unclear whether BBR improve hepatic MTTP function. So we further explored the mechanism of BBR reducing liver fat content by regulating MTTP.

Materials and methods: After Sprague- Dawley (SD) rats (n=16) were fed with 8 weeks of high-fat diet (HFD, 51% energy from fat, 4.64 kcal/g), NAFLD model was successfully established. Then rats with NAFLD were randomly divided into two groups, one of which were treated with BBR orally at 200mg/(kg d) (n=8, BBR+HFD group) and another group fed with vehicle (0.5% methylcellulose) as HFD control (n=8, HFD group), for sixteen weeks. Meanwhile, SD rats with normal diet (12.5% energy from fat, 3.2kcal/g) received the vehicle as normal control (n=8, ND group). At the end of the experiment, all rats were sacrificed and samples of liver tissue were taken for quantitative real-time PCR analysis and hepatic fat content measurement after overnight fasting. Total blood samples were also collected for serum lipoprotein profiles.

Results: Liver triglyceride content is significantly lower in BBR treatment group than in HFD group ($p<0.05$, Fig A), although it was higher than in the normal control. The results of quantitative real-time PCR showed that treated with BBR for 16 weeks upregulated hepatic MTTP mRNA level approaching that of normal control ($p<0.05$, Fig B), and MTTP gene expression declined by 70%in livers from rats in the HFD group in contrast to ND group. Accordingly, the protein levels of MTTP were higher in BBR-treated group than in HFD group (Fig C). Serum lipoproteins were separated using fast protein liquid chromatography (FPLC) (Fig D). The contents of apoB100 and apoB48, in the fractions were visualized by Western blotting. These results showed that TG-rich VLDL particles were significantly higher in BBR-treated group than HFD group according to area under the curve (AUC) (Fig E) and the levels of apolipoprotein B (apoB) -100 and -48 in isolated VLDL fractions were higher in BBR-treated group than HFD group (Fig F).

Conclusion: BBR can improve fatty liver by upregulating MTTP expression to increase hepatic VLDL-TG secretion in SD rats induced by a high-fat diet.

cAMP response element binding protein H, CREBH decreases hepatic lipogenesis

H.-S. Kim[1], M.-K. Kim[1], A.-K. Min[2], N.-K. Kim[1], G.-S. Jung[1], Y. Seo[1], I.-K. Lee[2], K.-G. Park[1];
[1]Department of Internal Medicine, Keimyung University School of Medicine, [2]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is closely associated with insulin resistance state, such as obesity and type 2 diabetes. Sterol regulatory element binding protein-1c (SREBP-1c) is one of the major regulators of the expression of genes involved in hepatic triglyceride synthesis. Hepatic expression of SREBP-1c is regulated by insulin-induced activation of liver X receptor (LXR) and specific protein 1 (Sp1). Endoplasmic reticulum-bound transcription factor families are shown to be involved in the control of various metabolic pathways. Here we show a novel function of

ER-bound transcription factor, cAMP response element binding protein H (CREBH), in the regulation of hepatic lipogenesis
Materials and methods: To demonstrate that CREBH expression is influenced by insulin, we determined hepatic CREBH expression during fasting and after the refeeding of control and streptozotocin-induced diabetic rats. We next examined whether CREBH decreased hepatic lipogenesis and SREBP-1c expression in high fat diet fed mice, using tail vein injection of adenovirus encoding the active form CREBH. Finally, we examined the mechanism by which CREBH inhibits *h*epatic SREBP-1c expression.
Results: We found that fasting induced but feeding suppressed CREBH expression. However, feeding did not suppress its expression when endogenous insulin was eliminated by treatment with streptozotocin. Insulin treatment decreased CREBH expression in cultured hepatocytes, suggesting that the refeeding-suppression of CREBH expression is mainly mediated by insulin. Adenovirus-mediated overexpression of CREBH inhibited insulin- and LXR agonist, TO901317-stimulated SREBP-1c mRNA expression in cultured hepatocytes. Moreover, adenovirus-mediated overexpression of CREBH inhibited hepatic steatosis in animal models through an inhibition of SREBP-1c expression. Transient transfection and gel shift assays showed that CREBH inhibited the activities of LXR and Sp1, known mediators of insulin-dependent SREBP-1c expression.
Conclusion: Collectively, these data suggest that CREBH could be a novel negative regulator of hepatic lipogenesis. This raises the possibility that CREBH can be therapeutic target to prevent the development of fatty liver disease in patients with insulin resistance.

762

The effect of metformin on liver mitochondria and lipid metabolism in NAFLD

M. Cahova[1], Z. Drahota[2], O. Oliarnyk[1], Z. Cervinkova[3], O. Kucera[3], H. Dankova[1], L. Kazdová[1,2];
[1]Department of Diabetes and Metabolism, Institute for Clinical and Experimental Medicine, Prague, [2]Department of Bioenergetics, Institute of Physiology AV CR, Prague, [3]Faculty of Medicine Charles University, Hradec Kralove, Czech Republic.

Background and aims: Metformin is a weak inhibitor of complex I of mitochondrial respiratory chain (MRC) what may negatively influence the cellular energy balance. Our study was designed to determine the effect of long-term high-fat diet administration in combination with metformin treatment on the lipid metabolism in liver, oxidative capacity of liver mitochondria and sensitivity of the liver to the ischemia reperfusion injury.
Material and methods: Male Wistar rats were fed standard (SD) or high-fat diet (HFD, 60% of calories derived from lard) for 10 weeks. Half of the HFD group was administered metformin in food (150 mg/kg b.wt.) for the last 5 weeks of the feeding period. In a separate experiment, animals were subjected to the warm liver ischemia induced by 20 min clamping of portal vein 2 days prior decapitation.
Results: HFD resulted in TAG accumulation in liver (3±0.3 vs 38±4.6 umol/g; p<0.001) and diminished liver glycogen content (219±18 vs 280±13 umol/g p<0.05). The effect of the diet was further potentiated by metformin (TAG: 73±2.5 umol/g, p<0.001; glycogen 169±6 umol/g, p<0.01). The increased activity of liver lysosomal lipase (LAL) in HFD group suggests the enhanced breakdown of endogenous TAG. Concomitantly, an increased expression of diacylglycerolacyltransferase-1 (DGAT-1) was found what indicates the increased FA reesterification. Metformin in combination with HFD further increased both LAL activity and DGAT-1 expression compared with HFD alone. The stimulatory effect of metformin on endogenous TAG degradation is supported by the elevated ketogenesis in HFD+Met group. HFD decreased the oxidative capacity of liver mitochondria on all tested substrates (glutamate + malate p=0.045; glutamate + malate + ADP p= 0.05; palmitoylcarnitine p=0.043; succinate p=0.051). Metformin potentiated the deleterious effect of HFD on mitochondria but only in animals that underwent liver ischemia (HFD+Met vs HFD: glutamate + malate + ADP p=0.042; palmitylcarnitoin p=0.025). We proved 40% decrease of in vitro activity of NADH:cytochrome c oxidoreductase in HFD+Met vs HFD alone. Liver ischemia resulted in the increased formation of lipoperoxidation products (HFD > SD). Metformin had no additional effect. In animals subjected to the liver ischemia, the activity of antioxidative enzymes (SOD, GSH-Px, catalase) were significantly lower in HFD vs SD group. Metformin treatment of HFD animals resulted in 70-80% increase in the activity of all tested enzymes.
Conclusion: The administration of metformin in combination with HFD worsened hepatic steatosis but it was not associated with the impairment of TAG degradation. On the contrary, the activity of lypolitic enzyme (LAL) was elevated. Metformin also potentiated HFD-induced impairment of mitochondria what deteriorated their ability to utilize released FA by mitochondrial oxidation and re-directed them into ketogenesis. TAG accumulation in liver significantly worsened the oxidative stress in liver ischemia/reperfusion. Metformin stimulated the activity of antioxidant enzymes but this was NOT accompanied by concomitant decrease in lipoperoxide formation. This fact could be interpreted as the adaptive response of the cell to the increased reactive oxygen species formation due to the impairment of MRC.

Adiponutrin, a lipid droplet surface enzyme - evidence for regulation by ChREBP, SREBP1c and FXR in human hepatocytes

J. Perttilä[1], S. Caron-Houde[2], B. Staels[2], H. Yki-Järvinen[3], V.M. Olkkonen[1];
[1]Minerva Medical Research Institute, Helsinki, Finland, [2]Institut Pasteur de Lille, INSERM UMR 545, Lille, France, [3]Department of Medicine, Division of Diabetes, University of Helsinki and Minerva Medical Research Institute, Helsinki, Finland.

Background and aims: Adiponutrin, encoded by the PNPLA3 gene, belongs to the family of patatin-like domain containing enzymes. A non-synonymous sequence variation, encoding an isoleucine to methionine substitution at amino acid 148 (rs738409; I148M), has been consistently associated with a markedly increased hepatic fat content in humans with non-alcoholic fatty liver disease. Adiponutrin is reported to show in vitro triglyceride lipase and acyltransferase activities, but its physiologic function and regulation are poorly known. We aim to eludicate (i) transcriptional regulation of PNPLA3, (ii) its subcellular localization in human hepatocytes, and (iii) expression pattern of adiponutrin in human tissues.
Materials and methods: PNPLA3 regulation was studied in a new cell line, immortalized human hepatocytes (IHH). The cells were treated for 24 h with agonists/antagonists of LXR, FXR, PXR, SREBP, PPARα, or PPARγ, followed by qPCR quantification of PNPLA3 mRNA. Human PNPLA3 cDNA was isolated, and the I148M variant was generated by site-directed mutagenesis. Wild-type and I148M cDNAs were expressed in IHH and visualized by confocal microscopy. Expression of adiponutrin protein in human subcutaneous adipose tissue and liver was studied by Western blotting.
Results: PNPLA3 mRNA was induced by high glucose, dependent on ChREBP. The oxysterols 25- and 22(R)-hydroxycholesterol suppressed the mRNA, in the absence of effect by the LXR agonist T0901317, suggesting regulation of PNPLA3 by SREBP1c. Furthermore, stimulation of FXR by chenodeoxycholic acid or GW4064 suppressed PNPLA3. Both wild-type adiponutrin and the I148M variant were found to localize extensively on lipid droplets in IHH cells. Western analysis demonstrated abundant presence of adiponutrin protein in both human subcutaneous adipose tissue and liver.
Conclusion: The results are consistent with a function of adiponutrin associated with up-regulation of hepatic lipogenesis by carbohydrate feeding. PNPLA3 expression is positively controlled by central transcription factor systems responsive to glucose and insulin, ChREBP and SREBP1c, which enhance glycolysis and lipogenesis. PNPLA3 is suppressed by FXR, an effect possibly mediated via SREBP1c. Location of adiponutrin on lipid droplets suggests its intimate involvement in neutral lipid metabolism on the droplet surface.

764

Discovery of a novel *in vivo* active heterocyclic inhibitor of stearoyl-CoA desaturase

M.D. Voss, G. Zoller, A.W. Herling, G. Biemer-Daub, H. Matter, A. Pfenninger, M. Kohlmann;
Research and Development, Sanofi-Aventis, Frankfurt am Main, Germany.

Background and aims: Stearoyl-CoA desaturase (SCD1) is linked to the pathogenesis of obesity, dyslipidemia and type 2 diabetes. SCD1 is rate-limiting in the synthesis of monounsaturated 16:1 n-7 and 18:1 n-9 fatty acyl-CoAs and catalyses an essential part of lipogenesis. Here, we describe the identification, *in vitro* properties and *in vivo* efficacy of a novel heterocyclic small molecule SCD1 inhibitor.
Materials and methods: SCD1, cytochrome b5 reductase, FADS1 and FADS2 activities were determined in rat liver microsomes. Cellular human

and rat enzyme activities were measured in HepG2 and H4IIE hepatoma cell lines, respectively. Metabolic stability was determined in liver microsomes, cell permeability in CaCo-2 cells. Male obese ZDF rats were used to assess *in vivo* effects on serum desaturation indices, body weight, blood glucose and triglycerides in a 4 weeks multiple dose study. All clinical blood parameters were determined by commercially available diagnostic kits on a Hitachi 912 device, serum fatty acid desaturation indices were analysed by LCMS.
Results: Hexahydropyrrolopyrole SCD1 inhibitors were discovered and a compound representative of the series was optimised to an IC50 of 7nM in rat liver microsomes and a cellular IC50 of 56 nM in rat H4IIE hepatoma cells. The compound is highly selective towards fatty acid desaturases 1 and 2 (D5 and 6 desaturases) and cytochrome b5 reductase (> 400-fold). Low metabolic lability in liver microsomal fractions (4%) and high cell permability ($401x10^7$ cm/s) allowed an *in vivo* assessment in ZDF rats. After 5 days dosing at 20mg/kg *per os* serum C_{max} levels reached 4520 ng/mL and a plasma half life of 14 hrs could be determined. After 28 days of treatment at 20mg/kg, the compound significantly decreased body weight (-8.1±0.5%), serum triglycerides (-56.1±4.0%), blood glucose levels (-28.0±3.4%) and HbA1c (-22.8±5.8 %) compared to vehicle in the obese animals. In parallel, serum fatty acid desaturation indices were decreased (-94.8±11.6%). However, fissures of the eye lid, alopecia and inflammation of the skin were observed from day 14 on in all animals treated with the same metabolically active dose.
Conclusion: In summary, we described *in vitro* and *in vivo* properties of a novel, potent and selective SCD1 inhibitor that improved body weight, blood glucose and triglycerides in an animal model of obesity, type 2 diabetes and dyslipidemia. However, the favourable *in vivo* features of systemic SCD1 inhibition shown in this study were accompanied by adverse target-related effects observed in skin. Thus, systemic SCD1 inhibition by small molecules might therefore not represent a feasible approach for the treatment of chronic metabolic diseases.

Expression of nonalcoholic fatty liver disease associated adiponutrin variant I148M causes triglyceride accumulation
H.A. Jones, C. Fernandez, S. Larsson, C. Holm;
Experimental Medical Sciences, Lund University, Lund, Sweden.

Background and aims: The strong association between adiponutrin variant I148M and hepatic steatosis has recently highlighted adiponutrin as an important putative enzyme involved in lipid metabolism. Based on structural similarities to patatin domain-containing proteins, adiponutrin has been proposed to have both lipolytic and lipogenic capabilities, but its function and physiological relevance in lipid homeostasis are still unknown. Despite efforts, the biological role of adiponutrin and the mechanisms underlying the strong association between the I148M adiponutrin variant and elevated hepatic triacylglycerol levels remain elusive. Here we examine the impact of the polymorphism encoding I148M in adiponutrin on lipid storage in HEK293 cells.
Materials and methods: HEK293 cells were transfected with human wild type, I148M, C99G and K434G variants of adiponutrin. 36h post transfection the cells were analyzed with regard to lipid content, profile of extracted lipids and lipid accumulation by imaging of stained cells.
Results: Overexpression of wild type or the I148M variant of adiponutrin leads to significant increases in triglyceride content [30% ($p<0.05$) or 2-fold ($p<0.001$), respectively] compared to control transfected cells. Interestingly, the I148M variant caused a significantly greater [50% ($p<0.001$)] lipid accumulation compared to wild type adiponutrin. Thin layer chromatography of extracted lipids from parallel experiments confirmed that both wildtype and the I148M variant of adiponutrin cause accumulation of triacylglycerol in cells, leaving monoacylglycerol and diacylglycerol content unaffected, and that I148M more effectively promotes triglyceride formation compared to wild type. Imaging experiments of fixed cells revealed increased neutral lipids contained in visibly larger lipid droplets in wild type and I148M transfected cells compared to control. The control variants C99G and K434G behaved similarly to wild type adiponutrin in all experiments.
Conclusion: The presented data where expression of human recombinant adiponutrin promotes lipid storage suggests a primarily lipogenic rather than a lipolytic role for adiponutrin. Our data showing an increased lipogenic potential of the I148M variant of adiponutrin, compared to wild type, corroborates the strong association between I148M and liver steatosis in patients.

Adipocyte control of cancer cell growth
V. D' Esposito[1], F. Passaretti[1], A. Hammarstedt[2], R. Valentino[1], G. Perruolo[1], P. Mirra[1], C. Miele[1], U. Smith[2], F. Beguinot[1], P. Formisano[1];
[1]DBPCM e IEOS/CNR, Università degli studi di Napoli, Napoli, Italy, [2]Department of Molecular and Clinical Medicine/Diabetes, Institute of Medicine, Sahlgrenska Universitetssjukhuset, Göteborg, Sweden.

Obesity is one of the most challenging and growing health problems, worldwide. Epidemiologic studies now provide compelling evidence that obesity is a risk factor for both cancer incidence and mortality. In particular, obesity increases rates of breast cancer in postmenopausal women and is associated with a more poor survival and increased recurrence of disease, regardless the menopausal status. It is now becoming clear that adipocytes, which represent very abundant cell types surrounding cancer cells, particularly in the mammary gland, could influence several aspects of tumorigenesis, from promoting local invasion to angiogenesis and metastasis. However, the molecular mechanisms involved in the adipocyte control of the malignant phenotype remain poorly understood. We have studied the mechanisms by which adipocytes may affect breast cancer cell phenotypes. We have obtained evidence that conditioned medium (CM) of adipocytes derived from human mammary adipose tissue and from subcutaneous abdominal fat biopsies was capable to elicit growth of MCF7 breast cancer cells. This was also observed when mature adipocytes were obtained from undifferentiated precursors isolated from the stromal-vascular fraction (SVF). Similarly, CM from 3T3-L1 cells induced growth of MCF7 cells, in a time-dependent manner. In particular, CM from fully differentiated adipocytes was 2-fold more effective than CM from pre-adipocytes in inducing MCF7 growth. Cell cycle analysis by flow cytometry revealed that these changes are due to reduced apoptosis instead of increased proliferation. Multiplex screening for growth factors in the CM revealed that VEGF, FGF and PDGF secretion is higher by SVF cells than by adipocytes, suggesting a major involvement of SVF in promoting angiogenesis. In contrast, the content of IGF-1 produced by adipocytes is two-fold higher than that released by pre-adipocytes. Thus, IGF-1 could be a good candidate in mediating survival effect of adipocyte CM. Moreover, treatment of MCF7 with the IGF-1R inhibitor AG1024 reverted the adipocyte CM effect on cell growth. In conclusion, adipocyte-derived factors promote breast cancer cell growth by inhibiting apoptosis. This effect is more evident for factors released by adipocytes than by pre-adipocytes and is, at least in part, mediated by IGF-1.

High dose detemir inhibits proliferation of a human bladder cancer T24 cell line independent of Akt and ERK pathway
S. Liu[1], Y. Li[2], Y. Liang[2], T. Lin[1];
[1]Research Center of Medicine, [2]Department of Endocrinology, The Second Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China.

Background and aims: Growing evidence indicated the involvement of mitogenicity of insulin and insulin analogues in the increased risk of carcinogenesis in diabetes subjects. This study was aimed to investigate the effect of insulin detemir in comparison to regular human insulin on proliferation of a human bladder cancer T24 cell line and the role of Akt and ERK in the process.
Materials and methods: T24 cells were cultured and treated with detemir or insulin at the indicated concentrations for different time courses. A specific inhibitor for ERK1/2 (PD98059) or Akt (LY294002) was used either alone or in combination with detemir or insulin to test the involvement of Akt and ERK pathway in detemir or insulin-induced cell proliferation as evaluated using cell counting kit-8 reagents. Protein levels of Akt, pAkt, ERK, pERK were detected by Western blotting.
Results: Human insulin time- and dose-dependently enhanced proliferation of T24 cell at the concentrations of 10 and 100IU/L after treatment for 48, 72 and 96 hours. However, detemir inhibited T24 cell growth at 100IU/L. Both insulin and detemir promoted phosphorylation of ERK and Akt at 15, 30, and 60 min of treatment. Although ERK inhibition significantly enhanced while Akt inhibition reduced T24 cell proliferation, insulin still promoted while detemir inhibited T24 cell growth in the presence of either Akt or ERK inhibitor.

Conclusion: Insulin promotes proliferation of T24 cells. Detemir inhibits T24 cell proliferation at high dose independent of Akt or ERK activation.

Anti-apoptotic activities of insulin and insulin-like growth factor (IGF) 1 in human osteosarcoma Saos-2/B10 cells
C. Schmid, C. Ghirlanda, M. Niessen;
University Hospital of Zurich, Switzerland.

Background and aims: Obesity, insulin resistance and hyperinsulinaemia are associated with an increased risk of growth progression of some cancer types and possibly also with enhanced survival of tumour cells. We studied anti-apoptotic effects of insulin and IGF 1 in a cell line which is critically dependent on IGF- or insulin- like signals for proliferation and survival in vitro.
Materials and methods: B10 cells were grown in serum-containing media and then exposed to serum-free test media. DNA synthesis was measured as 3H-thymidine incorporation during a pulse given 18-21 h following exposure to test media, and apoptosis was assessed after 4 h by an ELISA detecting cytosolic oligonucleosomes. Insulin/IGF 1 signalling was analysed by Western blotting.
Results: Effects of insulin and IGF 1 were dose-dependent: 0.4 nM IGF 1 or 20 nM insulin was required for half-maximal stimulation of DNA synthesis whereas 0.04 nM IGF 1 or 1 nM insulin resulted in half-maximal inhibition of apoptosis. Effects of insulin and IGF 1 were time-dependent: 1 nM IGF 1 or 100 nM insulin prevented apoptosis half-maximally when added for the last 1-2 (of a total of 4) h whereas sequestering IGF 1 (but not of insulin) by adding IGF-binding protein (IGFBP)-3 led to a half-maximal loss of protection from apoptosis within the last 1-2 (of 4) h. Insulin and IGF 1 both activated Akt/PKB to similar levels, but activation of ERK1/2 was higher in the presence of insulin (after stimulation for 4 h). Insulin or IGF 1 did not protect against apoptosis in the continuous presence of 100 nM wortmannin (4 h) which was associated with reduced phosphorylation of PKB but more than half-maximal protection was still found when wortmannin was added only for the last 3 h.
Conclusion: Continuous exposure to IGF 1 (suppressible by IGFBP-3) or to insulin (not suppressible by IGFBP-3) prevents B10 cell apoptosis, possibly dependent on Akt/PKB. Apoptosis appears to be more sensitive to regulation by IGF 1 and insulin than mitogenesis.

The role of juxtaposed with another zinc finger gene 1 on glucose-lipid metabolism and related genes *in vitro*
L. Du[1,2], L. Li[1,2], G. Yang[3];
[1]The Key Laboratory of Laboratory Medical Diagnostics in the Ministry of Education, [2]Department of Clinical Biochemistry, [3]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Epidemiologic studies have shown the association of Diabetes Mellitus (DM) with either increased or decreased risk of developing malignant tumors. Recently, a genome-wide association studies have suggested the association of JAZF1 (juxtaposed with another zinc finger gene 1) with DM and prostate cancer. JAZF1 encodes a 27 kDa nuclear protein containing three putative zinc finger motifs, and is expressed in a variety of tissues of mouse, with highest expression in adipose tissue and testis. however, little is known about the functions in regulating metabolism. In our study, we investigated the influence of an overexpression of JAZF1 on 3T3-L1 adipose cells and hepatoma carcinoma Hepa1-6 cells which represent target tissue for diabetes and insulin resistance.
Materials and methods: To survey the tissue distribution of JAZF1 in healthy C57BL/6J mice by real-time quantitative PCR(SYBR GreenI); Expression vector for JAZF1 gene was constructed and transient transfected into 3T3-L1 preadipocytes and hepatoma carcinoma Hepa1-6 cells, respectively. Oil Red O staining for 3T3-L1 preadipocytes was carried out. The mRNA levels of JAZF1, GLUT1,GLUT4, FAS(fatty acid synthetase), ACC(acetyl-CoA carboxylase), SREBP1(Sterol Regulatory Element Binding Protein1), and HSL(Hormone Sensitive lipase) implicated in glucose and lipid metabolism were determined by RT-QPCR; JAZF1 protein levels were measured by western blot.
Results: JAZF1 is expressed in all tissues examined, with highest levels detected in testis and adipose tissues and lowest levels in muscle and kidney. In JAZF1-transfected adipocytes, JAZF1 mRNA expression and protein levels were significantly higher than control cells after transfected 48h. The mRNA levels of HSL was increased obviously($P<0.05$)in JAZF1 transfection group compared with negative control and empty vector group, and the relative expression of FAS,ACC,SREBP1 mRNA were decreased significantly(all $P<0.001$). However, the mRNA levels of GLUT1,GLUT4 were not changed (all $P>0.05$). Intercelluar lipid accumulation was decreased obviously ($P<0.05$)by Oil Red O staining and colorimetric in JAZF1-transfected cells compared with negative control and empty vector group.
Conclusion: There were a widely expression of JAZF1 in various organization of C57BL/6J mice, it indicated that JAZF1 might play a role in maintaining normal physiological function. These results show that overexpression of JAZF1 in 3T3-L1 cells can reduce lipid synthesis, increase lipolysis and improve lipid accumulation. We speculate that JAZF1 might provide a new potential therapeutic target for obesity and diabetes.

Induction of HSP72, a potential novel therapeutic approach for metabolic syndrome and type 2 diabetes

T. Kondo[1], R. Matsuyama[1], K. Sasaki[1], S. Morino-Koga[2], M.A. Suico[2], J. Kawashima[1], H. Motoshima[1], N. Furukawa[1], K. Tsuruzoe[1], N. Miyamura[1], H. Kai[2], E. Araki[1];
[1]Metabolic Medicine, [2]Molecular Medicine, Kumamoto University, Kumamoto, Japan.

Background and aims: Life-style related diseases, such as type 2 diabetes and metabolic syndrome (MS) are associated with reduction of heat shock protein (Hsp) 72 levels, and activation of Hsp72 expression may improve insulin resistance and visceral adiposity. The present study investigated whether Hsp72 induction using an apparatus which provides Mild Electrical stimulation with Thermotherapy (MET) could reduce visceral adiposity and improve glucose homeostasis in mice models of type 2 diabetes and in human with MS.
Materials and methods: C57/BL6 mice fed with high-fat feeding and db/db mice were treated with MET (12V, 55 pulses per second, 10 min at 42°C, twice a week for 8~10 weeks) or sham-treatment. High-fat fed mice were also treated with Hsp72 inducer geranylgeranylacetone (GGA), 200 mg/day for 4 weeks. Forty eligible male MS subjects were randomly assigned to two groups, each containing 20 subjects. Group I was subjected to a 12-week intervention period of MET (12V, 55 pps, 60 min at 42°C, 4 times a week) followed by 12 weeks with no treatment. The order was reversed in Group II.
Results: High-fat fed mice and db/db mice presented following favorable changes upon treatment with either MET or GGA administration. 1) Reduction of visceral (-34%) and subcutaneous (-44%) fat mass, 2) Reduction of fasting glucose (-20%) and insulin levels (-38%), 3) Improvement of glucose homeostasis and insulin resistance, 4) Upregulation of serum adiponectin levels (+94%), 5) Improvement of insulin signaling in liver. We observed following results upon MET treatment in male subjects with MS. 1) Reduction of visceral fat (-5.8%) and total abdominal fat (-3.3%) area, but not subcutaneous fat area, 2) Decrease of waist circumference (-0.7%), but not body weight, 3) Reduction of both systolic (-4.2%) and diastolic blood pressure (-2.7%), 3) Improvement of fasting plasma glucose (-4.9%) and insulin levels (-8.5%) as well as HOMA-IR (-11.7%), QUICKI (+2.4%) and composite WBISI (+17.2%), 4) Trend of reduction in HbA1c (-1.2%, p=0.065), 5) Decrease of insulinogenic index (-10.2%), 6) Amelioration of inflammatory cytokines or adpokines, such as hs-CRP (-27.4%), adiponectin (+9.3%), leptin (-8.3%) and TNF-α (-10.2%), 7) Decrease of WBC (-5.4%) and LDL-C (-5.3%) levels.
Conclusion: Hyperthermia with mild electrical stimulation improved glucose homeostasis and insulin resistance in mice models of type 2 diabetes and human with MS. Therefore, this treatment could have beneficial impacts on body composition and metabolic abnormalities in life-style related diseases. Type 2 diabetes could be one of the other targets for the treatment.

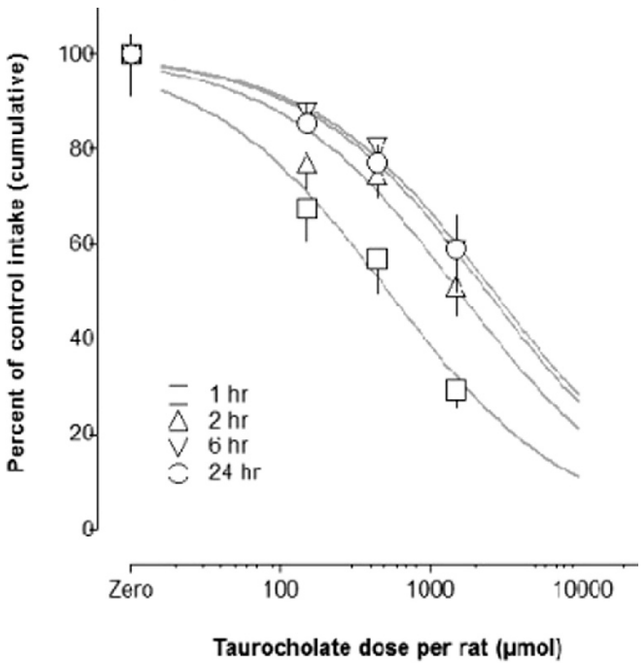
Taurocholate delivered to the distal gut suppresses food intake and causes weight loss in rats

A.A. Young, G. Gedulin, M. Tryon, B.R. Gedulin;
Physiology, Satiogen Pharmaceuticals Inc., San Diego, USA.

Background and aims: Bile acids (BA's), the endogenous ligands for TGR5 receptors located on enteroendocrine L-cells, stimulate the secretion of the anorexigenic hormones GLP-1, PYY and oxyntomodulin, as well as GLP 2. Several orally administered TGR5 agonists do not evoke robust anorexic effects, perhaps by failing to reach colon and rectum, wherein the peptide content and secretory response of L cells can be over 2 orders of magnitude higher than in more accessible stomach and duodenum.
Materials and methods: Effects of rectal BA's on food intake were studied in [male] Sprague Dawley rats fasted 12 hours. In a series of dose-response experiments, each of 12 rats received each of 4 taurocholate (TCA) doses 0 (control), 0.15, 0.45 or 1.5 mmol in 3 replicates of a 4x4 Latin Square design. In separate study, taurocholate was delivered to the distal gut of [male] Sprague Dawley rats via an intraperitoneally implanted osmotic minipump (Alza) and intraluminal catheter at a rate of 6 µmol/hour (n=6) for 7days; control group minipump delivered saline only (n=6).
Results: Cumulative food intake measured up to 24 hours after rectal delivery of TCA was dose dependently decreased. Relative to controls, food intake in TCA treated rats was reduced by 32%, 43%, and 70% by 0.15, 0.45 and 1.5 mmol doses, respectively (P<0.05, 1-way ANOVA). The ED50 for TCA-induced reduction in cumulative food intake at 1 hour was 1.6 mmol. For 24 hour intake, the value was 7.2 mmol. In the second study 10% weight loss induced by taurocholate delivered for 7days was greater than the 5% observed in surgical controls (P<0.05).
Conclusion: In conclusion, we have demonstrated an effect of rectally administered taurocholate to dose-dependently inhibit food intake in normal rats for up to 24 hours, and for sustained taurocholate delivery to the lower bowel to induce weight loss.



772

Weight loss during a hypo-caloric diet induces an anti-inflammatory response in adipose tissue

M. van Eijk[1], M. Brands[2], N.M. Lammers[2], H.P. Sauerwein[2], E. Endert[2], M.T. Ackermans[2], M.J. Serlie[2];
[1]Medical Biochemistry, [2]Endocrinology and Metabolism, Acadmic Medical Center, Amsterdam, Netherlands.

Adipose tissue of obese insulin resistant subjects is characterized by a low-grade inflammatory phenotype and reduced levels of adiponectin and GLUT4. The low-grade inflammation is associated with pro-inflammatory macrophages in adipose tissue. The aim of this study was to evaluate whether this inflammatory response is an early or late feature during the course of weight gain. Therefore, we studied the inflammatory changes in plasma and subcutaneous adipose tissue in healthy lean men before and after a positive energy balance resulting in modest weight gain, and a negative energy balance resulting in loss of the gained weight. We studied 9 healthy lean men (age 37 [27-43] years and BMI 23.6 [20.6-25.6] kg/m^2). The hypercaloric diet was calculated as 1.4 x caloric need to maintain body weight. After a median of 35 [28-43] days participants gained 7 [5.1-7.6]% of their initial body weight. The hypocaloric diet was calculated as 1.00x resting energy expenditure. At the end of the hypo-caloric diet participants returned to their initial weight. The protein, fat and carbohydrate content of the diets were 16%, 30% and 54% respectively. Participants were monitored weekly to assess body weight, body composition, and plasma leptin concentrations. Before the diet intervention and after the hypercaloric (HYPER) and hypocaloric (HYPO) diet, blood samples and abdominal subcutaneous adipose tissue (AT) biopsies were taken after an overnight fast to measure plasma concentrations and AT expression levels of inflammatory markers and adipokines. Plasma levels of leptin, adiponectin and MCP-1 were all increased in the HYPER state. In AT, inflammatory markers (TNF, IL10, MCP1, osteopontin) did not change significantly, but expression of the mannose receptor (MR) decreased significantly. Interestingly, expression of GLUT 4 in AT was significantly increased during the posi-

tive energy balance. During the period of the negative energy balance, plasma adiponectin, MCP-1 levels and resistin returned to baseline, while leptin levels decreased below baseline levels. In AT expression of adiponectin and a trend for decreased GLUT4 expression compared to baseline was observed. Interestingly, the expression of CD68, CD163 and MR increased in the HYPO state, indicating that there was a higher content of alternatively activated macrophages after the negative energy balance. In conclusion, in the early phase of a positive energy balance resulting in modest weight gain, a limited pro-inflammatory response in plasma is present. GLUT 4 expression is increased facilitating triglyceride formation. During a negative energy balance, alternatively activated macrophages are present in AT indicating an anti-inflammatory response which may be important in tissue remodelling.

773

Phentermine/topiramate combination therapy significantly improves glucose impairment in overweight/obese patients

L.F. Van Gaal[1], W.T. Garvey[2], B. Troupin[3], W.W. Day[3];
[1]Antwerp University Hospital, Antwerp, Belgium, [2]University of Alabama; Birmingham VA Medical Center, Birmingham, [3]VIVUS, Inc, Mountain View, USA.

Background and aims: Obesity, which is strongly linked to type 2 diabetes mellitus (T2DM), is on the rise. Impaired fasting glucose/impaired glucose tolerance (IFG/IGT) are prediabetic glycemic states associated with insulin resistance and increased risk of cardiovascular disease. A 56-week Phase 3 study (CONQUER) was performed to confirm the efficacy and safety of once-daily, low-dose, controlled-release phentermine/topiramate (PHEN/TPM CR) in overweight/obese patients with at least 2 comorbidities such as prediabetes or T2DM. In addition, this study evaluated the effects of PHEN/TPM CR on various glycemic parameters in a subgroup of patients with IFG/IGT.
Materials and methods: All subjects underwent oral glucose tolerance testing (OGTT) at baseline, Week 4, and Week 56. From this, a subgroup of subjects with IFG/IGT at baseline was defined using fasting serum glucose >5.55 mmol/L, or serum glucose >7.77 mmol/L 2 hours after a 75 g glucose load.
Results: Out of 2487 patients enrolled, 1635 (66%) were identified as having IFG/IGT. Patients were randomized to either placebo (n=655), PHEN/TPM CR 7.5/46 mg (7.5/46 [n=335]), or PHEN/TPM CR 15/92 mg (15/92 [n=645]); treatment with both doses of PHEN/TPM CR resulted in a significantly greater percent weight loss than placebo. For subjects with IGT/IFG, the mean percent weight loss at Week 56 with LOCF was 2.3% for placebo, 8.3% for 7.5/46, and 10.5% for 15/92. The table presents the results for change in HbA1c and fasting serum glucose from baseline to Week 56 (ITT-LOCF). Both PHEN/TPM CR doses led to significantly greater improvement vs placebo in HbA1c and fasting serum glucose. Further analysis showed that, among the subgroup of patients with IFG/IGT (per OGTT) who completed the study (n=562), achievement of normal OGTT was 44.2%, 63.1%, and 73.1% for placebo, 7.5/46, and 15/92, respectively (P<0.0001 vs placebo) (Table). The percentage of IFG/IGT subjects progressing to T2DM during the study was 15.3%, 6.9%, and 4.5% for placebo, 7.5/46, and 15/92, respectively. PHEN/TPM CR was well tolerated.
Conclusion: In addition to achieving significant weight loss, patients with IFG/IGT who were treated with PHEN/TPM CR achieved significant improvements in glycemic parameters and decreased incidence of progression to worsening glycemic status, suggesting prevention of progression to diabetes and/or reversion to normal glycemic status.

Change in Glycemic Parameters From Baseline to Week 56 in Subjects With Impaired Glucose (ITT-LOCF)

Once-daily, low-dose, controlled-release phentermine/topiramate results in significant clinical improvements in overweight/obese patients with type 2 diabetes

W.T. Garvey[1], B. Troupin[2], W.W. Day[2];
[1]University of Alabama; Birmingham VA Medical Center, Birmingham, [2]VIVUS, Inc, Mountain View, USA.

Background and aims: Weight loss can delay progression to type 2 diabetes mellitus (T2DM) and improve glycemic control in patients with T2DM. A 56-week Phase 3 trial (CONQUER) was conducted to evaluate efficacy and safety of low-dose, controlled-release phentermine/topiramate (PHEN/TPM CR) for weight loss in overweight/obese patients with and without T2DM, and effects on glycemic control and medication load in T2DM patients.
Materials and methods: In this randomized, double-blind trial, 2487 obese subjects meeting at least 2 criteria for the metabolic syndrome received placebo (n=994), PHEN 7.5 mg/TPM CR 46 mg (7.5/46 [n=498]), or PHEN 15 mg/TPM CR 92 mg (15/92 [n=995]). At baseline, T2DM subjects were treated with lifestyle intervention or metformin; they were managed to ADA standards of care. This T2DM subpopulation was further analyzed.
Results: At baseline, the mean weight of all randomized subjects was 103.1 kg, mean BMI was 36.6 kg/m^2, and mean HbA1c was 5.9%. In total, 338 (15.8%) patients had a previous diagnosis of T2DM or an elevated fasting glucose (FG) (>6.94 mmol/L) at baseline. Mean baseline HbA1c for the T2DM subpopulation was 6.8%; mean FG was 7.43 mmol/L. At Week 56, the least squares (LS) mean weight loss for placebo, 7.5/46, and 15/92, was 1.2%, 7.8%, and 9.8%, respectively, for the overall ITT-LOCF population (P<0.0001 for PHEN/TPM CR vs placebo). Those subjects completing 56 weeks of treatment on drug also experienced significant weight loss vs placebo (P<0.001): 1.6%, 9.6%, and 12.4% for placebo, 7.5/46, and 15/92, respectively. Among ITT-LOCF subjects with T2DM at baseline, LS mean weight loss was significant vs placebo at Week 56 (P<0.0001): 1.9%, 6.8%, and 8.8% for placebo, 7.5/46, and 15/92, respectively. During the study, a greater proportion of subjects with T2DM in the placebo group required an increase in concomitant antidiabetic medications than those in the PHEN/TPM CR groups (Table). LS mean decrease in HbA1c from baseline to Week 56 in subjects with T2DM (ITT-LOCF) was significantly greater with both doses of PHEN/TPM CR vs placebo (0.4%, 0.4% vs 0.1%; P<0.05). LS mean decreases from baseline in FG (mmol/L) were also greater in the PHEN/TPM CR groups vs placebo: 0.31, 0.54, and 0.66 for placebo, 7.5/46, and 15/92, respectively (P=0.0556 for 15/92 versus placebo; P=0.3325 for 7.5/46 vs placebo). PHEN/TPM CR was well tolerated with the majority of adverse events (AEs) being mild in severity. The most common AEs were tingling, dry mouth, constipation, altered taste, and insomnia.
Conclusion: In this study, patients with T2DM experienced significant weight loss with PHEN/TPM CR therapy. These results were associated with clinically meaningful improvements in glycemia through 56 weeks compared to placebo, despite increased use of diabetes medications in the placebo group. Thus, PHEN/TPM CR can enhance glycemic control in overweight/obese patients with T2DM.

Changes in Number of Antidiabetic Medications, Baseline to Week 56: Diabetic Population (ITT-LOCF)

Treatment	n	Subjects With Decrease n (%)	Subjects With No Change n (%)	Subjects With Increase n (%)
Placebo	157	4(2.5)	130 (82.8)	23 (14.6)
PHEN/TPM CR 7.5/46	67	2 (3.0)	62 (92.5)	3 (4.5)

Restoration of beta cell function in severely obese type 2 diabetic patients after gastric bypass surgery

B. Schultes[1], B. Ernst[1], B. Wilms[1], M. Thurnheer[1], E. Svehlikova[2], B.M. Obermayer-Pietsch[2], T.R. Pieber[2];
[1]Interdisciplinary Obesity Center, Kantonsspital St. Gallen, Rorschach, Switzerland, [2]Division of Endocrinology and Nuclear Medicine, Department of Internal Medicine, Medical University of Graz, Austria.

Background and aims: Gastric bypass surgery has been shown to frequently resolve type 2 diabetes but the mechanism underlying are incompletely understood. Here we report preliminary results on a systematic assessment of beta-cell function along with insulin sensitivity before and shortly after gastric bypass surgery in the first 6 type 2 diabetic patients of an ongoing study.
Materials and methods: Before and 8 to 21 days after the operation, patients were subjected to an OGTT as well as to a botnia clamp which combines an IVGTT with a subsequent hyperinsulinemic-euglycemic clamp. Established models were used to calculate varies indices of glucose metabolism. Known diabetes duration in our patients ranged from 1 to 14 years (mean ± SEM: 8.2 ± 2.0 years).
Results: Body weight decreased from 121.4 ± 9.2 to 113.7 ± 8.4 kg and BMI from 43.3 ± 1.5 to 40.7 ± 1.6 kg/m^2 (both $P < 0.005$) and diabetes medication was markedly reduced after the operation (before: 4 patients short- and long-acting insulin, average dose 56.5 ± 12.1 U/day and 51.5 ± 10.0 U/day, respectively, 6 patients metformin, one patients gliclazide; after: 4 patients long-acting insulin, average dose 21.5 ± 5.9 U/day, no short-acting insulin, no oral antihyperglycemic agents). Concentrations of HbA1c, fasting glucose, and 2 h glucose response to the OGTT were significantly reduced after surgery (all $P < 0.05$). None of the calculated indices of insulin secretion, e.g. acute insulin response (AIR), pointed to a significant improvement of beta-cell function (all $P > 0.5$) while indices of insulin sensitivity tended to increase (e.g. M-value 1.65 ± 0.59 vs. 3.67 ± 0.52; $P = 0.07$).
Conclusion: In contrast to previous studies in type 2 diabetic patients not treated with insulin with disease duration less than 6 years, we did not find an improvement in beta-cell function shortly after gastric bypass surgery. Thus, improved glucose metabolism soon after the operation appears to rely primarily on enhanced insulin sensitivity. However, these preliminary observations do not exclude a restoration of beta-cell function later after gastric bypass surgery.

Sleeve gastrectomy, only a restrictive surgical procedure?

D. Benaiges[1], A. Goday[1], J.M. Ramon[2], E. Hernandez-Rivas[1], M. Villatoro[1], J. Flores[1], M. Carrera[1], L. Grande[2], J.F. Cano[1];
[1]Endocrinology and Nutrition, [2]Surgery, Hospital Universitari del Mar, Barcelona, Spain.

Background and aims: Bariatric Surgery (BS) offers new therapeutic possibilities for subjects with morbid obesity (MO) and type 2 diabetes mellitus (DM2). Several studies suggest that the malabsorptive surgical procedures are more effective than restrictive techniques (Gastric Banding and Vertical Banded Gastroplasty) for the treatment of DM2. The aim of this study is to assess the efficiency of Laparoscopic Sleeve Gastrectomy (LSG) vs Laparoscopic Y de Roux Gastric By-pass (LYRGB) in the normalization of glucose metabolism disorders, and to analyze subsequent changes in Insulin Resistance (IR) in patients with and without glucose metabolism abnormalities.
Materials and methods: Cohort study of MO patients consecutively admitted for BS (LYRLB or LSG). Patients were grouped according to glucose metabolism state categories defined by ADA: DM2, impaired fasting glucose (IFG) and normal glucose metabolism (nonDM). IR was defined as a Homeostasis model assessment (HOMA-IR) ≥3.29 (Spanish population study). The following clinical and metabolic parameters were gathered at baseline, 3, 6 and 12 months after the procedure: venous blood glucose, HbA1c, HOMA-IR and estimated glucose disposal rate (EGDR). DM2 remission was defined as: 2 consecutive glucose measurements <126mg/dl, HbA1c <6.5% and no need for hypoglycemic drugs. IFG normalization was defined as: 2 consecutive glucose values <100mg/dl and HbA1c <5.7%. And IR resolution was characterized by a HOMA <3.28. Multivariate analysis were used to identify predictive factors for remission of glucose metabolism disorders and IR.
Results: 140 patients were included with a mean age of 45.6 ± 7.9, 85.6 % women, and mean BMI of 45.7 ± 5.0 Kg/m2. 67.9 % underwent a LYRGB and 32.1 % a LSG. Baseline characteristics of DM2 patients in both surgical interventions were comparable in terms of age, sex, need of hypoglycemic drugs, DM2 duration, glucose levels and HbA1c. Clinical outcomes at three months follow-up in both surgical groups were as follows: 1) 80.6% DM2 remission, 2) 89.5% IFG remission, 3) IR remission was achieved in 79.2 % of the DM2 patients, in 95.9 % of IFG subjects and in 97.7 % of the nonDM subjects. Independent predictors for a significant decrease in HOMA-IR at 12 months were EGDR and BMI (R^2=0.449) . No predictive factors for DM2 or IFG resolution were identified.
Conclusion: A restrictive surgical procedure like LSG is equally effective as malabsortive techniques in terms of weight loss, improvement of glucose metabolism and IR. EGDR negatively correlates with IR improvement after the BS.

	LSG	LYRGB	significance
Age (years)	44.4 ± 9.8	46.1 ± 8.2	p>0.05
BMI (Kg/m^2)	44.5 ± 45.5	46.3 ± 4.7	p>0.05
EGDR (mg/kg^{-1} min^{-1})	8,9 ± 2.1	8,2±2.4	p>0.05
HOMA-IR	4.2 ± 2.4	4.6 ± 3.0	p>0.05
DM2/ IFG (%)	15.6 / 44.4	26.3 / 40.0	p>0.05
IR (%)	67.6	67.1	p>0.05
Percentage of excess weight loss 12 months	82.9 ± 18.8	80.9 ± 16.6	p>0.05
HOMA-IR decrease 12 months	2.2 ± 1.5	3.6 ± 3.0	p>0.05
IR remission (%) 12 months	95.5	100	p>0.05
IFG remission (%) 12 months	85	94.6	p>0.05
DM2 remission (%) 12 months	100	92	p>0.05

Respiratory function in massive obesity: effects of surgically induced weight loss

J. Aron-Wisnewsky[1,2], C. Minville[3,4], A. Basdevant[1], J. Gonzalez[5], P . Clement[1,2], J.-L. Pepin[3,4];
[1]Nutrition and Endocrinology Department and CRNH-Ile de France, [2]75006, UMR S 872, Centre de Recherche des Cordeliers, Université Pierre et Marie Curie-Paris6, [3]INSERM ERI 17, HP2 laboratory (Hypoxia: Pathophysiology), Joseph Fourier University, Grenoble, [4]Rehabilitation and Physiology Department, Grenoble University, [5]Pulmonary Medicine and Intensive care unit, Paris, France.

Background and aims: In obese patients, adipose tissue around the rib cage and abdomen and in the visceral cavity loads respiratory system, increases work of breathing and reduces lung volumes particularly functional residual capacity (FRC) and expiratory reserve volume (ERV). Obesity also affects airway caliber with a slight reduction in expiratory flows. To date, limited data are available on the effects of bariatric surgery on respiratory function. We aimed to systematically investigate respiratory function of obese patients at baseline (T0) and 6 months (T6) after surgically induced weight loss.
Materials and methods: We conducted a retrospective analysis of a single center observational cohort of 77 obese patients (BMI = 47.8 ±6.7 kg/m^2) who underwent laparoscopic bariatric surgery (63 Roux-en-Y-gastric bypass; 14 gastroplasty). Arterial blood gazes and respiratory function tests including lung volume and flow measurements were assessed at T0 and T6.
Results: Patient's characteristics at baseline were as follows: 74% women, mean age = 43 ± 11 years, mean PaO2 = 82.9 ± 9.2 mmHg, mean PaCO2= 40.2 ± 6.2 mmHg. Mean values of forced expiratory volume in 1 second (FEV_1), vital capacity (VC), FEV_1/VC and total lung capacity (TLC) as expressed in % of predicted values were in the normal range. FRC and ERV were significantly reduced (absolute values and % of predicted: 2.0 ± 0.6L; 65 ± 16% and 0.53 ± 0.33L; 44 ± 25% respectively). On flow volume loops, expiratory flows at 25% of VC was also decreased (3.5 ± 0.9L/min; 52 ± 26%). After bariatric surgery (T6), we observed a significant weight loss (Δ-30.6 ± 13kg; -22.4 % of the initial BMI, p<0.0001) along with a significant improvement from baseline in VRE (absolute values and % of variation from baseline: Δ0.4 ± 0.3L; +44 ± 95%; p<0.0001), expiratory flows at 25% of VC (Δ0.13 ±0.39L/min; +9 ± 33%; p=0.03), FRC (Δ0.4 ± 0.4L; +16 ± 18%; p<0.0001), FEV_1 (Δ0.2 ±0.2L/min; +7 ± 9%; p=0.004) and FVC (Δ0.2 ± 0.3L, +6 ± 8%, p=0.007). Moreover, we found an inverse association between BMI reduction and increases in ERV, expiratory flows at 25% and 50% of VC (p=0.0035; p=0.037; p=0.04, respectively). Changes in PaO2 and PaCO2 were close to a statistically significant improvement (ΔPaO2= 7.3 ± 22 mmHg; p=0.06, ΔPaCO2= -3.9 ± 9

mmHg; p=0.07). Whereas 25/77 patients (32.5%) were hypoxemic at baseline (PaO2<80mmHg), 13 improved with weight loss at 6 months. All of the 4 being hypercapnic at baseline normalized their PaCO2.
Conclusion: To our knowledge, this is the largest cohort evaluated in terms of respiratory function before and 6 months after surgically induced weight loss. Morbidly obese patients exhibited reduced expiratory reserve volume with increased risk of airway closure demonstrated by significant reduction of expiratory flows at 25% of VC. This is associated with underventilation of some lung regions explaining low PaO2 in more than 30% of our cohort. Importantly, surgically induced weight loss allowed a significant improvement in pulmonary functions, volumes, flows and blood gazes.

Massive body mass loss leads to reduced endoplasmic reticulum stress and activation of autophagy in adipose tissue
E.P. Araujo, C.E.C. Nuñez, B. Geloneze, J.C. Pareja, L.A. Velloso;
University of Campinas, Brazil.

Background and aims: Endoplasmic reticulum stress (ER-stress) has emerged as an important link between nutritional overload and insulin resistance. High consumption of nutrients, especially saturated fats, induces the activation of ER-stress, which promotes inflammatory gene transcription and eventually the activation of pro-apoptotic signaling. The inflammatory proteins induced by this process mediate the activation of serine/threonine kinases in insulin sensitive tissues, contributing for the impairment of the insulin signal transduction. Body mass loss is one of the most efficient means for correcting glucose intolerance. The reduction of the adipose tissue production of inflammatory factors plays a central role in this process. However, the molecular and cellular mechanisms behind this outcome are poorly understood. Here, we explore the hypothesis that massive body mass loss is accompanied by reduced ER-stress in the adipose tissue.
Materials and methods: Ten obese patients were submitted to subcutaneous adipose tissue biopsy before and 6-8 months after bariatric surgery. Ten, age matched lean subjects were employed as controls. Samples were used for evaluation of protein and mRNA expression of markers of ER-stress, inflammation and autophagy. Metabolic parameters were evaluated at the same time-points as biopsies.
Results: Body mass index dropped from 48±4 to 37±4 (controls, 24±2), which was accompanied by the reduction of blood insulin, leptin, TNF-α, IL-6 and C-reactive protein and by the increase in the blood levels of adiponectin. Significant reductions in protein (amount/activity) and/or mRNA levels of the ER-markers, PERK, eIF2α, IRE1α, spliced XBP1 and JNK were observed. The inflammatory proteins TNFα, IL-1β, IL-6, IKK and SOCS-3 were also negatively modulated by body mass loss. Interestingly, markers of autophagy, such as beclin, LC3 and CHOP increased after body mass loss.
Conclusion: The reduction of ER-stress may be an important molecular/cellular mechanism linking the loss of body mass with reduced adipose-tissue-driven inflammation. The induction of autophagy in this setting may contribute to prolonged adipocyte survival during catabolism and may play an important role in body mass regain, which is commonly seen in patients undergoing restrictive dieting programs.

Identification of determinants for weight reduction in children and adolescents with overweight and obesity with an standardised questionnaire and electronic health technology
A. Kaps[1], G. Bieber[2], R. Schiel[1,3];
[1]MEDIGREIF Inselklinik Heringsdorf, Ostseebad Heringsdorf, Germany, [2]Fraunhofer Institute, IGD Rostock, [3]University of Applied Sciences, Faculty for Diabetes and Health Management, Rheine, Germany.

Background and aims: The prevalence of overweight/obesity increased markedly during the last decades. It is associated with a high risk for diabetes and death. Patients often fail to reach sufficient long-term weight reduction. The aim of the trial is the development of an research programme to identify the determinants of overweight/obesity.
Materials and methods: 97/117 children/adolescents with overweight/obesity admitted to our hospital to participate in a structured treatment and teaching programme (STTP) due to overweight/obesity were included in the trial (age 13.4±2.6 years, BMI 31.2±5.0 kg/m², BMI-SDS 2.49±0.52). All children filled out a standardized questionnaire and participate in an intelligence test. To asses physical activity and eating habits electronic health technology was used (Fraunhofer-Institute, IGD, Germany). The system consists in a motion sensor integrated in a mobile phone (DiaTrace). The system analyses kind, intensity & duration of physical activity and eating habits.
Results: During participation in the STTP the children/adolescents had a weight reduction of 6.97±2.91 kg (p<0.001). BMI/BMI-SDS decreased from 31.3±5.2 kg/m²/2.50±0.50 to 28.7±4.9 kg/m² (p<0.001)/2.15±0.57 (p<0.001). The IQ was 99.6±12.9 points for the vocabulary test & 96.4 ±15.3 points for the analytical test. There were significant correlations between weight reduction and body weight at onset of the trial (r=-0.564, p<0.001), family climate (r=0.265, p=0.046), stress management (r=0.273, p=0.04), eating behaviour (r=-0.272, p=0.001), intrinsic motivation (ß=0.732, p<0.001), intrafamilial conflicts (ß=0.461, p=0.04), introspection (r=-0.331, p=0.012) duration of physical activity measured with MoSeBo/DiaTrace (ß=-0.438, p=0.002) and body fat mass (ß=-0.393, p=0.005). Multivariate analysis shows associations with the motivation for weight reduction (ß= 0.388, p=0.021), conflicts at school (ß= -0.299, p=0.036), self-regulation of emotions (ß= 0.575, p<0,001), education of the father (ß= -0.246, p=0.039) and physical activity assessed with DiaTrace (ß=-0.181, p=0.044). Comparing self-reported physical activity with objective assessment by the diatrace system there were significant differences (p<0.001). In general the duration of physical activity documented by children and adolescents was much higher than the objective assessment. Similarly, the real caloric intake was higher than recommended (p=0.085).
Conclusion: 1. There are important psychological parameters with a association with the weight reduction. On the background of the identified parameters a new questionnaire will be developed and used in a larger multicenter cohort. In a 1 year follow-up examination all determinants for weight reduction will be evaluate. After that a systematic adaptation of the STTP should follow. 2. There are differences between patients´ self-assessment and objective perception of physical activity and eating habits. Discrepancies in perception is a important determinants of poor long-term outcome. Using modern electronic health technology allows the objective assessment of kind, intensity and quantity of physical activity and eating habits. This could be an important advanced method to improve the therapy of obesity and diabetes.

Fatty acid oxidation rate is higher in obese women than obese men

F. Shojaee-Moradie[1], K. Backhouse[1], I. Sarac[1], M. Stoliniski[1], D. Robertson[1], J.D. Bell[2], E.L. Thomas[2], D. Russell-Jones[1], M. Umpleby[1];
[1]Diabetes and Endocrinology, University of Surrey, Guildford, [2]Metabolic and Molecular Imaging Group, Imperial College London, United Kingdom.

Background and aims: Excess plasma fatty acids have been associated with insulin resistance, increased hepatic triglyceride production and cardiovascular risk. Women have been shown to produce more fatty acids than men relative to their resting energy expenditure. This study investigated whether the oxidation rate of circulating fatty acids is also greater relative to resting energy expenditure in obese women compared to men matched for age and BMI.
Materials and methods: 12 obese men (58 ± 2y, BMI 31 ± 1 kg/m^2)(mean ± SEM) and 12 postmenopausal obese women (59 ± 1y, BMI 32 ± 1 kg/m^2) were studied. Resting energy expenditure (REE) and total lipid oxidation was measured by indirect calorimetry. An iv infusion of [U-^{13}C] palmitate was administered with measurements of plasma palmitate enrichment and $^{13}CO_2$ production rate to calculate palmitate production, metabolic clearance (MCR) and oxidation rate. On a separate day an iv infusion of [1,2-^{13}C]acetate was given with measurements of $^{13}CO_2$ production rate to correct palmitate oxidation for the loss of label in the Krebs cycle. Whole body fat mass was measured by MRI. Statistical analysis was by unpaired t test.
Results: Palmitate turnover rate (Ra), MCR and oxidation rate (Ox) expressed as kg fat free mass (FFM) were significantly higher in obese women than in obese men (Ra: 4.5 ± 0.3 v 2.8 ± 0.2 umol/min/kgFFM, p<0.001); MCR 31.2 ± 1.5 v 20.7 ± 1.4 ml/min/kgFFM, p<0.001; Ox 1.6 ± 0.1 v 1.2 ± 0.1 umol/min/kgFFM, p<0.002). Palmitate Ra expressed as kg fat mass was not significantly different between genders. Plasma palmitate concentrations and total lipid oxidation expressed as kg FFM, measured by indirect calorimetry, were not different in the women and men. When corrected for REE both palmitate Ra, MCR and Ox remained significantly greater in women than men (p<0.003, p=0.006, p=0.03 respectively). When subset of subjects (7men, 7 women) were matched for adiposity (men: 38 ± 3 kg fat, women 38 ± 1 kg fat), these measurements remained significantly greater in women than in men (p=0.003, p<0.01 and p=0.002 respectively).
Conclusion: This study shows that when adjusted for FFM and REE, palmitate oxidation rate was higher in women than men suggesting that women oxidise more circulating fatty acids than men. Since total lipid oxidation adjusted for FFM did not differ between men and women this suggests that men oxidise more non-plasma lipids.

Metabolomics reveals differential metabolic regulation at the catabolic-anabolic switchpoint during oral glucose challenge testing in women after recent gestational diabetes

W. Peissner[1], M. Wallner[2], M. Bunk[2], A.-G. Ziegler[2], B. Koletzko[1];
[1]Div. Metabolism and Nutrition, LMU Munich University, Dr. von Hauner Children's Hospital, [2]Research Group Diabetes at the Helmholtz Centre Munich, Diabetes Research Institute, Germany.

Background and aims: Insulin-mediated postprandial suppression of non-esterified fatty acid release from adipose tissue is acknowledged as an important physiological function to protect non-adipose tissues from lipotoxic effects. Functional metabolic characterization of the catabolic-anabolic transition in the early postprandial state is supposed to provide valuable insight into. The PINGUIN trial is a randomized intervention trial assessing the protective potential of Vildagliptin medication for the prevention of diabetes type 2 in a high-risk population of women after recent gestational diabetes. Extensive follow-up and longitudinal monitoring by repeated oral glucose and food challenge testing provides a unique opportunity to systematically analyze changes in metabolic systems performance during diabetes progression.
Materials and methods: After overnight fasting, eligible women and volunteers completed oral glucose tolerance testing or consumed a standard breakfast meal. Serum samples were drawn at 6-8 times between 20 min before and 120 min after the oral food challenge. Direct infusion- and HPLC-tandem mass spectrometry were used to quantitate amino acids, acylcarnitines, hexoses, sphingomyelins, phosphocholines and lysophosphocholines (180 metabolites in total) from serum sample time series.
Results: Targeted metabolomics analyses were able to show consistent responses of distinct metabolite groups rapidly following oral glucose or food uptake. Most notable changes occurred in short-chain acylcarnitines that represent the decreasing production and utilization of ketone bodies and organic acids. Similarly, levels of medium- and long-chain acylcarnitines and distinct long-chain sphingomyelins dropped rapidly, representing the suppression of fatty acid release from adipose tissue. Reaction profiles of amino acids were divided, prominent postprandial decrease was seen in all branched-chain and urea cycle-related amino acids, mirroring the halting of protein catabolism. Interestingly, fasting levels of several closely related acylcarnitines and amino acids were strikingly different in women with recent history of gestational diabetes as compared to healthy young volunteers. Some of the women showed differing metabolite pattern without significant changes over time, in contrast to the general decreasing trend. The significance of this finding has to be further evaluated by extending the study to include more subjects.
Conclusion: Assessment of dynamic metabolite changes during oral challenge testing reveals consistent pattern of metabolic regulation. Functional phenotyping by metabolomics techniques may be able to improve stratification of preventive intervention in populations at high risk for diabetes and metabolic syndrome.

Serum concentrations and tissue expression of components of insulin-like growth factor-axis in patients with type 2 diabetes mellitus and obesity: the influence of very low calorie diet

M. Haluzik, J. Krizova, M. Mraz, D. Haluzikova, M. Bartlova, P. Kavalkova, J. Drapalova, P. Trachta, V. Hanusova, M. Matoulek, Z. Lacinova, S. Svacina;
3rd Department of Medicine, Charles University, Prague, Czech Republic.

Background and aims: Insulin-like growth factor (IGF)-axis plays a complex role in glucose homeostasis, insulin sensitivity and pathogenesis of diabetes mellitus. The aim of the present study was to measure serum levels and tissue expression of selected components of the IGF-axis in type 2 diabetic patients at baseline and after dietary intervention.
Materials and methods: 12 obese females with type 2 diabetes mellitus (T2DM) and 10 healthy lean, sex- and age-matched controls (C) were included into the study. Serum concentrations of selected biochemical and hormonal parameters were measured by commercial ELISA and RIA kits. The expression analysis of genes for IGF-I and -II, insulin-like growth factor binding protein(IGFBP)-1 and -3 and insulin-like growth factor-receptor (IGF-R) in subcutaneous adipose tissue (SCAT) and isolated peripheral monocytes was performed by RT PCR at baseline and after 2 weeks of very low calorie diet (VLCD, energy intake 2500 kJ/day). The study was approved by the Ethical Committee of General University Hospital in Prague.
Results: Compared to C group, T2DM group had significantly increased fasting glucose, insulin and leptin concentrations and mRNA expression of IGF-R and IGFBP-3 in peripheral monocytes. Serum levels of IGF-I and adiponectin and mRNA expression of IGF-I, IGFBP-3 and IGF-R in SCAT were significantly reduced in T2DM group. IGF-II expression did not differ between the groups. mRNA expression of IGFBP-1 was not detected in either SCAT or peripheral monocytes. mRNA expression of IGF-I and IGF-II was not detected in peripheral monocytes. In SCAT, the mRNA expression of IGF-I, IGFBP-3 and IGF-R negatively correlated with BMI, insulin, glucose and HOMA index. IGF-R mRNA expression in peripheral monocytes positively correlated with BMI, insulin and HOMA index, while IGFBP-3 mRNA expression positively correlated only with BMI. Two weeks of VLCD significantly decreased body weight, and improved glycemia, insulin resistance and lipid profile. VLCD further significantly decreased serum IGF-I levels and increased IGF-I mRNA expression in SCAT. mRNA expression of other studied parameters was not influenced by VLCD.
Conclusion: Our results suggest that decreased mRNA expression of IGF-1 in SCAT and increased expression of IGFBP-3 in peripheral monocytes may induce local metabolic disturbances in adipose tissue contributing to development of insulin resistance and type 2 diabetes mellitus.

Visceral fat reduction is associated with increased IL-10 levels in obese subjects that underwent caloric restriction

G. Formoso[1], M.P.A. Baldassarre[1], M. Taraborrelli[1], M. D'Adamo[2], P. Di Fulvio[1], N. Di Pietro[3], A. Nicolucci[4], A. Tartaro[5], A. Pandolfi[3], A. Consoli[1];
[1]Medicine and Aging Sciences, University of Chieti, Chieti Scalo, [2]Department of Internal Medicine, University of Rome, [3]Biomedical Sciences, University of Chieti, Chieti Scalo, [4]Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, Santa Maria Imbaro, [5]Department of Clinical Sciences and Bio-imaging, University of Chieti, Chieti Scalo, Italy.

Background and aims: Obese subjects are characterized by a low grade inflammatory state that may contribute in predisposing them to develop atherosclerosis. An excess of adipose tissue, particularly in intra-abdominal depots, is thought to play a role in the pathophysiology of the metabolic syndrome, closely linked to insulin resistance, and to increase the risk of cardiovascular disease. Although circulating levels of proinflammatory cytokines as well as other inflammation markers have been shown to be elevated in human obesity, little is known about the role of anti-inflammatory cytokines in this setting. IL-10 is a major inhibitor of cytokines synthesis; it suppresses macrophage function and inhibits the production of proinflammatory cytokines. Recent studies have shown an increase in IL-10 levels after caloric restriction. However, scant data exist about the effects on plasma IL-10 levels of the loss of visceral and/or subcutaneous fat tissue (VF and SF respectively). Aim of the present study was to verify whether changes in insulin sensitivity and in plasma levels of IL-10 together with several adipokines such as TNFα, IL-6 and Leptin specifically correlate with changes in VF or SF.
Materials and methods: We measured VF and SF by Magnetic Resonance (MRI), plasma levels of glucose, insulin, IL-10, TNFα, IL-6 and Leptin before and after a caloric restriction induced weight loss of at least 5% of the original body weight, in 14 (4 men, 10 women) obese subjects (BMI 34.4±6.5 Kg/mq).
Results: As we expected, weight loss improved insulin sensitivity (Quicki index= 0.35±0.03 vs 0.37±0.04, p<0.05), increased IL-10 levels (3.41±1.98 pg/ml vs 4.63±1,03pg/ml, p<0.05) and reduced TNFα , IL-6 e leptin levels (2.52±1.32 pg/ml vs 1.60±1.52 pg/ml; 2.32±0.42 pg/ml vs 1.64±0.64 pg/ml; 56.1±30.2 ng/ml vs 37.2±29.3 ng/ml respectively, p<0.05 for all). Moreover we observed a significant correlation between the amount of VF loss and the improvement in insulin sensitivity (r=0.44, p<0.05) and between the percent reduction in VF and the percent reduction in both TNFα (r=0.56, p<0.05) and IL6 (r=0.19, P<0.05) plasma levels. On the contrary, no correlation was observed between the investigated parameters and either the amount or the percentage of SF lost. Furthermore, in a multiple regression analysis, the amount of VF loss independently correlated with the increase in IL-10 levels.
Conclusion: These data suggest that the reduction in visceral but not in subcutaneous adipose tissue is associated with an improvement in the inflammatory pattern characterizing obesity and, specifically, that a loss in VF is associated with increased plasma levels of the anti-inflammatory adipokine IL-10.

784

Weight loss in women is followed by a significant decrease of 11β hydroxysteroid dehydrogenase 1 in subcutaneous adipose tissue

K. Simonyte[1], T. Olsson[1], I. Näslund[2], J.-E. Angelhed[3], L. Lonn[4], C. Mattsson[1], E. Rask[5];
[1]Public Health and Clinical Medicine, Medicine, Umea, Sweden, [2]Surgery, Orebro University Hospital, Sweden, [3]Medicine, Sahlgrenska Academy, Gothenburg, Sweden, [4]Radiology and Vascular Surgery, Rigshospitalet, Copenhagen, Denmark, [5]Medicine, Orebro University Hospital, Sweden.

11ß hydroxysteroid dehydrogenase (11βHSD1) catalyzes the conversion of the inactive glucocorticoid compund cortisone into active cortisol, in a tissue-specific manner. This enzyme may have a key role in the development of central obesity and obesity-related complications. In humans, positive associations between 11βHSD1 in subcutaneous (sc) adipose tissue and different features of metabolic syndrome, including body mass index (BMI), blood pressure, and insulin sensitivity, have been reported. Furthermore, we have recently shown a positive correlation between 11βHSD1 and phosphoenolpyruvate carboxykinase C (PEPCK) - a key enzyme in gluconeogenesis. This supports a role for glucocorticoids in fatty acid (FA) metabolism in obesity, leading to increased rate of FA re-esterification in adipose tissue. In this study we evaluated peripheral glucocorticoid metabolism in the subcutaneous adipose depot before and after stabilized weight loss and explored a putative link between 11βHSD1 and fatty acid recycling in women. Twenty-seven obese women underwent gastric bypass surgery with collection of sc fat biopsies and blood before and two years after surgery. Computed tomography (CT) was used to estimate regional fat distribution and the amount of liver fat. Adipose tissue expression of 11βHSD1, leptin, adiponectin, PEPCK, sterol regulatory element binding protein (SREBP), fatty acid synthase (FAS), perilipin and hormone sensitive lipase (HSL) expression levels were analyzed with real-time PCR; serum leptin and adiponectin levels with ELISA. Two years after bypass surgery, there was a 69% mean decrease in BMI associated with a 2-fold reduction in the sc depot and 4-fold decrease in the intraabdominal depot. Liver attenuation decreased, reflecting decreased liver fat. 11βHSD1 gene expression decreased 4-fold after weight loss. Leptin and adiponectin expression decreased significantly, with concomitantly significantly decreased circulating leptin and increased adiponectin levels. There were no differences in the expression of genes involved in gluconeogenesis (PEPCK), lipolysis (perilipin, HSL), and lipogenesis (FAS, SREBP) after weight loss. Before surgery, sc 11βHSD1 gene expression correlated only to waist circumference, whereas after the significant weight reduction, 11βHSD1 mRNA levels correlated with multiple measures of central fat accumulation, ie. BMI, L4 total adipose tissue area and the intraabdominal fat area (p<0.01, p<0.05 and p<0.001; respectively). A significant correlation between 11βHSD1 and PEPCK observed before surgery was lost after weight loss (r=0.57, *P*<0.05 vs r=-0.02) respectively). Weight loss links to metabolically favorable changes in 11βHSD1 expression in fat and circulating levels of leptin and adiponectin. The reduction of 11βHSD1 in fat after weight loss suggests that up-regulation of this enzyme is a consequence, rather than a cause, of obesity. No significant differences in gene expression of the key enzymes involved in lipid metabolism and lack of associations to anthropometric measurements suggest that weight loss *per se* does not directly affect transcription of these genes in sc adipose tissue.

11β- HSD1 in subcutaneous adipose tissue of SGA adults is dysregulated but not associated with metabolic disorders

E. Carreira[1], T. Meas[1,2], M. Rauh[3], Y. Wang[4], C. Poitou[5], K. Clément[5], J. Dotsch[3], C. Lévy-Marchal[1,2];
[1]INSERM U690, [2]Université Paris 7, France, [3]Department of Pediatrics, University of Erlangen-Nueremberg, Germany, [4]CIC Robert Debré, [5]INSERM U872, Paris, France.

Background and aims: The mechanisms relating being born small for gestational age (SGA) and the later risk of metabolic disorders are not yet fully understood. Adipose 11β-HSD1 activity and expression has been positively associated with metabolic syndrome in animals and humans. In humans, no *in vivo* studies have explored 11β-HSD1 activity and gene expression in subcutaneous adipose tissue of SGA subjects.
Materials and methods: 39 subjects SGA, birth weight< 10th percentile, were matched on gender and age with 36 subjects born Appropriate for Gestational age (AGA - 25th <birth weight<75th percentile); the two groups were stratified according to body fat content into "low fat mass" (20 SGA and 18 AGA) and "high fat mass" (19 SGA and 18 AGA) subjects. Basal and stimulated activities of the 11β-HSD1 enzyme were assessed in the effluent of microdialysis performed in the abdominal subcutaneous wall *in vivo*. mRNA expression was measured by real-time quantitative PCR in subcutaneous adipose tissue.

Results:

	"low fat mass" AGA N= 18	"high fat mass"AGA N= 18	"low fat mass" SGA N= 20	"high fat mass" SGA N= 19	P low/high fat mass	P SGA/ AGA
Gender (M/F)	8/10	7/11	10/10	8/11		
Age (yr)	29.6 (26.1;33.3)	31.6 (26.7;32.9)	30.1 (24.7; 34.2)	32.6 (28.3 ; 35.0)		
Body fat (%)	21.8 (15; 28)	35.9 (29.5; 42)	22 (15; 27)	39 (28.7; 41)		
M clamp (mg/min/kg lean body mass)	12.5 (10.8; 14.8)	6.4 (4.8 ; 8.3)	10.5 (8.6 ; 15.0)	5.5 (4.1 ; 8.2)	*0.001*	0.68
Microdialysis						
Basal 11β-HSD1 activity (cortisol/ Cortisone)	1.7 (1.3; 1.9)	2.2 (0.9; 3.5)	1.9 (1.5 ; 2.5)	2.3 (1.5 ; 2.9)	0.83	0.69
Activation of 11β-HSD1 at nadir (%)	12.5 (5.7; 45.9)	18.8 (7.9; 95.7)	8.3 (5.3; 3.8)	7.3 (5.2; 15.1)	0.06	0.004
Fat Biopsy	N= 18	N=14	N=16	N=16		
Expression of 11β-HSD1 (arbitrary unit)	119 (90; 147)	249 (147; 407)	193 (112; 262)	341 (198; 421)	0.0001	0.18
Adipocyte diameter (μm)	84.5 (77.3; 89.8)	98.4 (90.3;110.3)	76.2 (56.4; 79.0)	99.3 (87.3;103.7)	<0.0001	0.003

Conclusion: The *in vivo* stimulated 11β-HSD1 activity was decreased in subjects born SGA as compared to adults born AGA. 11β-HSD1 gene expression was associated with body fat but not with birth weight. We also found an independent effect of both birth weight and body fat on adipocyte diameter. Moreover, expression and activation of 11β-HSD1 were strongly associated with the adipocyte diameter in SGA group, suggesting a "protective" role of the decreased size of adipocytes on the development of metabolic complications. It is therefore unlikely that local glucocorticoid metabolism in subcutaneous fat plays a major role in the development of the metabolic complications associated with being born SGA.

Labisia pumila var alata extract down-regulates 11-beta hydroxysteroid dehydrogenase type-1 and corticosterone levels in overweight ovariectomized rats

M. Fazliana[1,2], W. Wan Nazaimoon[2], H.F. Gu[1], C.-G. Östenson[1];
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Diabetes and Endocrine Unit, CDNRC, Institute for Medical Research, Kuala Lumpur, Malaysia.

Background and aims: The enzyme 11-beta hydroxysteroid dehydrogenase type-1 (Hsd11b1) is highly expressed in key metabolic tissues including adipose and liver. In rats, it converts inactive 11-dehydrocorticosterone to active corticosterone (CORT). Activation of Hsd11b1 and glucocorticoid receptor could result in the production of excess tissue glucocorticoids which affects glucose homeostasis, insulin action and adiposity, all of which are associated with the development of type-2 diabetes and visceral obesity. Ovariectomy (OVX) rats have increased body weight and decreased insulin sensitivity in relation to estrogen deficiency. Our microarray analysis of liver of OVX rats has shown increased expression of Hsd11b1. Therefore, we examined Hsd11b1 expression and CORT levels on OVX rats after treatment with Labisia pumila var alata (LP), a Malaysian plant with phytoestrogen effects.
Materials and methods: Thirty-six Sprague-Dawley rats were ovariectomized (OVX) at 6-weeks of age and one group (N=7) undergone sham operation (SHAM). After two weeks, the rats were treated with oral gavage of LPva10, LPva20 and LPva50 extract (10, 20 and 50 mg/kg/day respectively), estrogen replacement (ERT) (0.625 mg/kg/day) for 30 days (n=7) or as controls (SHAM and OVX). Microarray analysis was done with liver tissue, followed by real-time RT-PCR of liver and adipose tissues. CORT levels in plasma were analyzed using ELISA and protein expressions were detected by Western blotting.
Results: OVX rats gained more body weight than SHAM rats (74.5 ± 3.7 g vs. 56.9 ± 3.6 g, $p < 0.05$). Treatment of OVX with LP50 or ERT significantly reduced the weight gain by 16.8% and 25.5%, respectively ($p < 0.05$ for both). CORT levels in OVX group increased significantly (135 ± 25 ng/ml, $p<0.05$) in comparison to SHAM (53 ± 22 ng/ml, $p<0.05$). The levels decreased in all LP10, LP20 and LP50 (85 ± 19 ng/ml, 95 ± 14 ng/ml and 92 ± 25 ng/ml respectively, $p < 0.05$ for all) and ERT (88 ± 16 ng/ml, $p < 0.05$). In adipose tissues, the Hsd11b1 mRNA level of OVX group increased by 55 % ($p<0.05$) in comparison to Sham, normalized in LPva10, LPva20 and LPva50 and but not significantly decreased in ERT treated rats. The Hsd11b1 mRNA levels in liver of OVX was increased by 75 % ($p < 0.05$) when compared to Sham and restored to normal level when given LPva extracts and ERT. Protein levels of Hsd11b1 were down-regulated in both adipose tissues and liver of LPva-treated rats, in comparison to Ovx rats (significant difference in all LPva groups and ERT, $p<0.05$).
Conclusion: OVX had increased body weight, increased adipose and liver expression of Hsd11b1 and elevated CORT levels. Treatment with LPva extracts, similar to ERT, normalized Hsd11b1 mRNA and protein levels in OVX rats, in parallel with decreased CORT levels. Based on our results, we hypothesize that anti-obesity effects of LPva are attributed, at least in part, to the inhibition of Hsd11b1 expressions in adipose tissue and liver. These changes suggest the use of LPva for a postmenopausal treatment and possibly, in other conditions related to metabolic syndrome.

Transgenerational non-genomic inheritance of glucose intolerance by neonatal overfeeding in mice

J.C. Jimenez-Chillaron[1], T. Pentinat[1], J. Cebria[1], M. Ramon-Krauel[2], R. Diaz[2];
[1]Endocrinology, Fundacio per la Recerca Sant Joan de Deu, [2]Endocrinology, Hospital Pediatric Sant Joan de Deu, Esplgues, Barcelona, Spain.

Background and aims: Epidemiologic evidence suggests that sub-optimal nutrition during foetal and/or postnatal development influences diabetes risk later in life. In addition, such environmentally-induced phenotypes may manifest in subsequent generations, even when the environmental triggers are not present anymore (transgenerational effects). We have previously generated a mouse model of neonatal over-nutrition (ON-F0) by culling offspring to 4 pups per dam during lactation. Neonatal overfeeding led to rapid early weight gain and later development of metabolic syndrome in adult mice, by age 6 months: i.e. obesity, dislipidemia, hyperglycaemia, hyperinsulinemia, insulin resistance and glucose intolerance.
Here we aimed to explore whether neonatal over-nutrition may influence metabolism of successive generations, F1 and F2.
Materials and methods: Control and ON males from the F0 generation were mated with non-sibling control females to generate the first generation-offspring, F1. At birth, all litters are adjusted to 8 pups per dam. Thus, contrary to the parental generation, ON-F1 pups are not neonatally overfed as com-

pared to their matched controls. We next repeated the breeding protocol, by using C-F1 and ON-F1 males, to obtain the second-generation offspring, F2. Likewise, all litters are equalized to 8 pups per dam to match normal nutrition during the neonatal period. Thus, an important consideration for the experimental design is that ON-F1 and ON-F2 male mice are not themselves overfed during lactation.
Results: We show that ON-F1 and ON-F2 male mice also develop several features of the metabolic syndrome, including fasting hyperinsulinemia (C= 0.22± 0.01 ng/ml; ON-F1= 0.44± 0.06**; ON-F2= 0.31± 0.05*; *p< 0.05, **p< 0.01), mild insulin resistance (HOMA-IR, C= 0.5± 0.04; ON-F1= 1.4± 0.21**; ON-F2= 0.7± 0.23, p= 0.1; **p< 0.01) and glucose intolerance by age 4 months. Impaired glucose tolerance in ON-F1 and ON-F2 mice appears be accounted for primarily by peripheral insulin resistance, since beta-cell function remains normal in these cohorts. Thus, here we show, for the first time, that neonatal overfeeding programs adult diabetes-related phenotypes not only to exposed individuals, but also to their offspring and grand-offspring. To note, transgenerational inheritance of insulin resistance occurs through the paternal lineage. Thus, transgenerational inheritance of the diabetic phenotypes must occur through, nutritionally-induced, modifications in cells of the germ line. It has been proposed that trans-paternal inheritance of such environmentally-acquired phenotypes might be mediated, in part, by epigenetic mechanisms.
Conclusion: In summary, nutritional challenges occurring during sensitive periods of development may have adverse metabolic consequences well beyond the lifespan of affected individuals and manifest in subsequent generations. Transgenerational progression of metabolic phenotypes through the male lineage supports a potential role for epigenetic mechanisms in mediating these effects.

Paradoxical response in feeding in short-time fasted rAAV-leptin treated mice
N. Ueno[1], A. Inui[2];
[1]Department of Internal Medicine, Kobe Seaside Hospital, [2]Department of Behavioral Medicine, Kagoshima University, Graduate School of Medical and Dental Sciences, Japan.

Background and aims: Leptin plays an impotant role in body weight regulation. Administration of leptin reduces food intake and body weight. However, we have shown that food intake did not decrease in rAAV-leptin treated (overexpression of leptin in the hypothalamus) wild type (wt) mice on a daily basis compared to control mice, though there was a decrease in body weight. To elucidate this discrepancy, we evaluated feeding behavior in short-term fasted rAAV-leptin treated wt mice.
Methods: rAAV-leptin and rAAV-GFP as a control was injected icv in wild type mice and daily (24 hours) food intake was measured. They were fasted for 3 hours and re-fed for 3 hours. Food intake was measured during the re-feeding period. Blood samples were collected before and after 3 hours fasting and blood glucose, plasma insulin, ghrelin and leptin levels were measured. Another set of mice (rAAV-leptin and rAAV-GFP treated) was fasted for 3 hours and glucose (1g/kg) was injected ip. The same blood samples were collected before glucose injection and 1 hour after glucose injection. Blood parameters same as above were measured in the same way.
Results: There was no change in total daily food intake in rAAV-leptin treated and control mice (control: 3.69Â±0.21, rAAV-leptin: 3.56Â±0.07 g). Food intake in rAAV-leptin treated mice during the re-feeding period was significantly increased compared to control mice (control: 0.19Â±0.04, rAAV-leptin: 0.38Â±0.05 g, p< 0.05). After fasting, blood glucose levels decreased (3.36Â±0.52 to 2.40Â±0.29 mmol/l, p< 0.01) in rAAV-leptin treated mice but not in control mice. Plasma ghrelin levels increased (1.32Â±0.32 to 3.92Â±0.75 ng/ml, p< 0.01) in rAAV-leptin treated mice but not in control mice. Plasma leptin levels decreased in control mice (5.45Â±0.79 to 3.81Â±0.45 ng/ml, p< 0.05) but stayed very low with no change in rAAV-leptin treated mice (0.36Â±0.07 to 0.29Â±0.04 ng/ml). Glucose injection decreased circulating ghrelin levels (11.10Â±1.21 to 2.42Â±0.28 ng/ml, p< 0.001) and increased leptin levels (0.42Â±0.12 to 0.77Â±0.15 ng/ml, p<0.05) in rAAV-leptin treated mice. No change was seen in the control group.
Conclusion: These results suggest that there was increased food intake when rAAV-leptin treated mice were fasted. Decrease in blood glucose or increase in circulating ghrelin in even short-term fasting periods may contribute to increased food intake in rAAV-leptin treated wt mice. This may explain, at least in part, the lack of difference in feeding behavior in rAAV-leptin treated wt mice and control mice. After glucose injection, reduction in circulating ghrelin and elevation in leptin levels may inhibit their increased food intake result in the normal daily food intake as if there is a feedback system.

Reduced insulin gene dosage prevents diet-induced obesity
A.E. Mehran, X. Hu, J.D. Johnson;
Cellular and physiological sciences, University of British Columbia, Vancouver, Canada.

Background and aims: Obesity has become a worldwide epidemic and can often lead to insulin resistance, hyperinsulinemia and type 2 diabetes, but the relationship amongst these phenomena remains enigmatic. Although insulin is a potent adipogenic hormone, it is thus far unclear whether hyperinsulinemia itself can be a causal factor in the pathogenesis of obesity and/or type 2 diabetes. Unlike humans, mice possess two non-allelic insulin genes. It has been previously established that mice lacking one of their two insulin genes are phenotypically normal. Furthermore, it is reported that only *Insulin 1* (*Ins1*) is exclusively expressed in the pancreatic beta cells whereas *Insulin 2* (*Ins2*) is also expressed in extra-pancreatic tissues where it can have non-endocrine functions. We therefore hypothesized that mice with only one active *Ins1* allele would be protected from diet-induced obesity and associated pathologies.
Materials and methods: To test hyperinsulinemia as an endocrine pathology, we used *Ins2* knockout mice. We compared mice with only a single copy of *Ins1* (Ins1+/-:Ins2-/-) with those with two copies of *Ins1* (Ins1+/+:Ins2-/-) with respect to the adverse effects of high-fat feeding. We studied body weight, glucose- and insulin- tolerance, insulin mRNA levels, islet insulin content, total body lipid content by NMR, epididymal fat pad weight, lipid accumulation in multiple tissues, and pancreatic beta cell mass by immunofluorescence microscopy.
Result: Ins1+/-:Ins2-/- mice were protected from adult-onset diet-induced weight gain compared with Ins1+/+:Ins2-/- controls ($P < 0.01$). High-fat fed mice with one or two active *Ins1* gene allele showed early elevated levels of circulating insulin when compared to chow fed mice of either of the genotypes. This was positively correlated with a slight increased overall body growth as per measured by tibial length at one year of age. However, one year old high-fat fed Ins1+/-:Ins2-/- mice had significantly reduced basal circulating insulin levels ($P < 0.01$), reduced insulin response to glucose stimulation, lower beta cell mass, lower whole-body fat ratio ($P < 0.05$), smaller epididymal fat pads ($P < 0.01$), smaller adipocytes, and no hepatic steatosis when compared with Ins1+/+:Ins2-/- mice on the same diet. Mice of either genotypes on the chow diet showed comparable phenotypes and were similar to that of observed in the high-fat fed Ins1+/-:Ins2-/- mice. Mice across all groups showed normal and comparable glucose tolerance and insulin sensitivity.
Conclusion: We have shown that prevention of diet-induced hyperinsulinemia through partial ablation of insulin gene can protect mice from obesity and its associated complications. Hyperinsulinemia may not just simply be an adaptive response to obesity-induced insulin resistance and may play a causal role in the pathogenesis of obesity and/or diabetes. Therapeutic interventions that reduce circulating insulin may be worth exploring in the context of obesity and pre-diabetes.

Micro-ribonucleic acid expression profiling and expression quantitative trait loci analysis in human gluteal and abdominal adipose tissue

M. Rantalainen[1], B.M. Herrera[2], G. Nicholson[1], Q.F. Wills[1], R. Bowden[1], M.J. Neville[3], J.C. Randall[2], A. Barrett[3], M. Allen[3], M.I. McCarthy[3], K.T. Zondervan[2], F. Karpe[3], C.C. Holmes[1], C.M. Lindgren[2];
[1]Department of Statistics, University of Oxford, [2]Wellcome Trust Centre for Human Genetics, University of Oxford, [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom.

Background and aims: Obesity is a large and growing public health problem associated with increased risks of type 2 diabetes, cardiovascular disease, hypertension and increased mortality. Adipose tissue distribution relates to morbidity with increased levels of abdominal adipose tissue relative gluteal adipose tissue associated with metabolic deregulation and related disease. Hence, characterization of the molecular phenotypes in these two adipose tissues is an essential starting point when attempting to understand molecular mechanisms associated with obesity and related disease. Here we characterise micro-RNA (miRNA) expression and how it contributes to the molecular phenotype in gluteal and abdominal adipose deposits, which are known to affect risk of obesity-related disorders.
Materials and methods: The expression of 1131 miRNAs was profiled in these two fat depots in 70 human subjects using the Illumina DASL miRNA beadarray. The study includes male and female subjects diagnosed with metabolic-syndrome as well as healthy controls. Here we focus on investigating tissue-specific miRNA expression. All subjects were genotyped using the Illumina HumanHap317 Beadchip, enabling assessment of whether there are individual genetic variants driving miRNA expression levels, by miRNA expression quantitative trait loci (eQTL) analysis. Tissue-differential expression was analysed using a linear mixed effects model with miRNA expression as response; tissue type, batch, gender, metabolic-syndrome status and age included as fixed effects; and a subject identifier included as random effect. Significance of the tissue effect was assessed by a permutation test of the likelihood-ratio statistic. A similar model and test was used for eQTL analysis, with the genotype included as an additive fixed effect. eQTL models were fitted separately for each tissue type.
Results: We found that 154 miRNAs were differentially expressed between gluteal and abdominal fat tissue (FDR corrected (Benjamini and Hochberg's method) p-value < 0.05). These miRNAs include hsa-miR-211 (p-value=0.006), hsa-miR-27b (p-value=0.006), hsa-miR-27a (p-value=0.011), hsa-miR-34a (p-value=0.020) and hsa-miR-143 (p-value=0.020), which have previously been reported to be associated with adipose tissue development, obesity and metabolic disorders. We detected 10 miRNA-eQTL candidates in gluteal adipose tissue and 23 miRNA-eQTL candidates in abdominal adipose tissue (nominal p-values < 0.002). Currently we are undertaking a confirmation study in 40 additional subjects, with the objective of replicating the current findings.
Conclusion: The results indicate a substantial difference in miRNA expression patterns between gluteal and abdominal adipose tissues, which may indicate an important role of miRNAs in contributing to the molecular phenotype of these two tissue types. Presence of miRNA-eQTLs indicate a direct genetic influence on the expression of specific miRNAs, and consequently also indirectly on the general molecular phenotype of gluteal and abdominal adipose tissue.

Human adipose tissue - a novel source of eotaxin-3

K. Vleugels[1], S. Glund[2], U. Buro[1], S.R. Bornstein[1], M. Ehrhart-Bornstein[1];
[1]Molecular Endocrinology, University Hospital Carl Gustav Carus, Dresden, [2]Department of CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany.

Background and aims: Obesity and overweight are major risk factors for chronic diseases, including type 2 diabetes, cardiovascular disease, hypertension and stroke, as well as certain forms of cancer. Obesity is characterized by a chronic, systemic low-grade state of inflammation. Adipose tissue secretes a multitude of factors, e.g. adipokines and cytokines that are involved in the body's homeostasis and metabolism. A causal relationship of obesity associated inflammation with metabolic disorders is indicated. We aimed at identifying cytokines released from human adipocytes and identified eotaxin-3 (CCL26). Eotaxin-3 is a member of the CC chemokine family, known to be expressed in several tissues, e.g. heart and lung, and is an important effector chemokine in allergic conditions. Eotaxin-3 acts mainly via the CCR3 receptor and is a potent chemoattractant for eosinophils. Additionally, evidence exists that eotaxin-3 acts as an antagonist on chemokine receptors CCR1, CCR2 and CCR5, suggesting a modulatory function of eotaxin-3 in inflammation. No data, however, exists so far on the expression in and/or secretion of eotaxin-3 from adipose tissue.
Materials and methods: Mature adipocytes and preadipocytes were isolated from white human adipose tissue obtained from healthy women undergoing surgical mammary reduction or liposuction. Preadipocytes and *in vitro* differentiated adipocytes were stimulated with IL-4, TNFα, and/or IFNγ. Visceral and subcutaneous fat tissue was obtained from patients undergoing abdominal surgery. Eotaxin-3 gene expression was determined with quantitative PCR. Eotaxin-3 secretion was measured with a specific RIA.
Results: In the present study, eotaxin-3 was expressed in most samples of human adipocytes and secreted constitutively. Intra-individual comparism of eotaxin-3 gene expression from subcutaneous and visceral fat depots showed higher eotaxin-3 levels in subcutaneous fat tissue. The eotaxin-3 expression in subcutaneous fat tissue is correlated to donor BMI. Furthermore, its expression was higher in adipose tissue than in isolated adipocytes. Preadipocytes and *in vitro* differentiated adipocytes expressed and secreted eotaxin-3 at low levels; its expression and secretion, however, was strongly induced by stimulation with IL-4, via STAT6 pathway, but not TNFα or IFNγ. Co-stimulation of preadipocytes with IL-4 and IFNγ decreased IL-4 induced eotaxin-3 expression; prestimulation with IFNγ decreased IL-4 induced eotaxin-3 expression in a dose-dependent manner.
Conclusion: We could identify human adipocytes as a novel source of eotaxin-3. Eotaxin-3 expression in subcutaneous fat tissue was positively correlated with BMI. Its expression is inducible by IL-4, an anti-inflammatory cytokine produced e.g. by adipose tissue. IFNγ inhibits IL-4 induced eotaxin-3 expression. A possible role of eotaxin-3 in obesity-associated disorders needs to be elucidated.

792

Human adipocytes express P2X7 receptors able to modulate some inflammatory responses in subjects with metabolic syndrome

A. Solini[1], S. Madec[1], C. Rossi[1], M. Chiarugi[2], E. Santini[1], A. Salvati[1], E. Ferrannini[1];
[1]Department of Internal Medicine, University of Pisa, [2]Department of Surgery, University of Pisa, Italy.

Backgound and aims: No information is available on the presence of P2X7 receptor in human adipocytes and their potential involvement in the chronic inflammation associated with metabolic syndrome (MS). Adipocytes were isolated from samples of visceral (VAT) and subcutaneous (SAT) adipose tissue of 40 patients with MS (defined as by ATP-III criteria) and 20 controls (CLT), recruited among patients undergoing laparoscopic cholecistectomy.
Materials and methods: We measured adipocyte gene expression of TNFα,IL-6 and PAI-1 (by realtime-PCR) and their plasma concentrations (ELISA), as well as gene and protein expression of P2X7 (using realtime-PCR, Western blot and immunocytochemistry). In a subgroup of 15 MS and 10 CLT we also evaluated P2X7 functional activity by measuring the effect of benzoyl-benzoyl-ATP (BzATP, a P2X7 specific agonist) and KN62 (a selective P2X7 blocker) on intracellular calcium fluxes (([Ca2+]I, by fluorimetry) and adipocytoke release (by ELISA).
Results: In VAT, TNFα, IL-6 and PAI-1 were more espressed in MS than in CLT (T/R ratio: 3.29±1.47 *vs* 1.79±1.19; 8.99±4.24 *vs* 5.65±4.03; 6.06±2.32 *vs* 2.91±0.34, p =0.005-0.0001). These differences were confirmed in SAT for IL-6 (3.56±1.56 *vs* 1.98±1.49, p=0.0004) and PAI-1 (3.87±1.87 *vs* 2.25±1.16, p=0.008), but not for TNFα (1.49±0.83 *vs* 1.24±0.68, p=ns). Plasma IL-6 and PAI-1 levels were higher in MS (IL-6: 2.81±1.55 *vs* 4.32±2.67 pg/ml, p=0.002; PAI-1: 32.08±11.21 *vs* 42.26±11.6 ng/ml, p=0.002). TNFα levels were higher in MS (3.22±1.26 *vs* 2.51±0.88 pg/ml, p<0.05). P2X7 mRNA, found both in VAT and SAT, was more abundant in MS than in CLT (T/R ratio: 2.13±0.68 *vs* 1.56±0.49 in VAT, p=0.0013 and 1.76±0.54 *vs* 1.46±0.41 in SAT, p=0.03). Protein expression confirmed this observation, with the typical "ring-like" arrangement of P2X7 receptor at the plasma membrane. BzATP 0.5 mM raised [Ca2+]i in VAT and SAT, without differences between MS and CLT (VAT:

+128 *vs* +98%, p=ns; SAT: +107 *vs* +110%, p=ns). In both MS and CLT cells BzATP induced IL-6 and TNFα release, partially inhibited by KN62 (VAT: IL-6 from 141±33 to 308±28 and 233±33 with KN62 in CLT; from163±27 to 318±64 and 254±59 pg/ml/mg tissue with KN62 in MS, p<0.0001; TNFα from 2.3±0.7 to 3.7±0.8 and 3.1±0.9 with KN62 in CLT; from 2.3±0.6 to 4.0±0.8 and 3.2±0.9 pg/ml/mg tissue with KN62 in MS, p<0.0001). BzATP did not induce any change in PAI-1 release, either in MS or CLT.
Conclusion: Human adipocytes express functionally active P2X7 receptors, which modulate the release of some inflammatory cytokines. Adipocytes from MS patients show an enhanced P2X7 receptor expression, which might contribute to the subclinical inflammatory status characterising these patients.

793

OCT-1 expression in adipocytes could contribute to increased metformin action in obese subjects
J.M. Moreno-Navarrete, F.J. Ortega, J.-I. Rodríguez-Hermosa, M. Sabater, G. Pardo, W. Ricart, J. Fernández-Real;
Department of Diabetes, Endocrinology and Nutrition. Institut d'Investigació Biomédica de Girona. CIBER Fisiopatología de la Obesidad y Nutrición CB06/03/010, Spain.

Background and aims: Metformin is an insulin-sensitizer widely used to treat type 2 diabetes mellitus. The metabolic effects of metformin on human adipocytes have not been well studied. Organic cationic transporters (OCT-1 and OCT-2) have been described to mediate metformin effects. We investigated the expression of *OCT-1* and *OCT-2* in human adipose tissue and during adipogenesis and evaluated their possible role in metformin action on human adipocytes.
Materials and methods: *OCT-1* and *OCT-2* gene expressions were analyzed in 118 visceral and subcutaneous adipose tissue, in stromo-vascular cells (SVCs) and mature adipocytes obtained from adipose tissue and during human pre-adipocytes differentiation. To test the functionality of OCT in response to metformin, co-treatments with cimetidine (OCT blocker, 0.5 and 5 mM) and metformin (5 mM) were made on human pre-adipocytes. The pre-adipocyte differentiation was monitored measuring adipogenic (*FASN, ACC1*, *PPARg* and *Adipoq*) and inflammatory (*IL-6* and *MCP-1*) gene expressions, the formation of lipid droplets and AMPK activity.
Results: *OCT-1* (but not *OCT-2*) gene expression was detected in subcutaneous and visceral adipose tissue. In both fat depots, *OCT-1* gene expression and protein was associated significantly with the obesity phenotype. *OCT-1* gene expression was significantly higher in SVCs than mature adipocytes (1.8-fold increased, p=0.01) and increased during differentiation the process in parallel to adipogenic genes. Metformin (5mM) decreased significantly the differentiation of human pre-adipocytes, decreasing the expression of lipogenic genes, lipid droplets accumulation, increasing AMPK activation. Co-treatments with cimetidine restored adipogenesis. Furthermore, metformin decreased *IL-6* and *MCP-1* gene expression in comparison with differentiated adipocytes.
Conclusion: OCT-1 might mediate the action of metformin on human adipose tissue.

The role of proliferin (PLF) in adipose tissue
T. Ishizuka, K. Kajita, T. Hanamoto, K. Fujioka, H. Okada, M. Yamauchi, Y. Uno, H. Morita;
Department of General Internal Medicine, Gifu University Graduate School of Medicine, Japan.

Background and aims: Last year, we reported that mature adipocytes have the ability to proliferate, which is enhanced with pioglitazone (Pio) treatment. We demonstrated that 5-Bromo-2'-Deoxyuridine (BrdU), a thymidine analog, incorporation into mature adipocytes was observed in BrdU-pretreated rats. Quantified results showed that amount of BrdU incorporation was equal in adipocytes and total stromal vascular fraction cells, and that BrdU incorporation was less active in subcutaneous adipocytes than visceral ones. Treatment with 0.005% Pio containing food for 2w increased BrdU incorporation predominantly in subcutaneous, but not visceral adipocytes. Moreover, we found that an increase in cell number and the cell cycle analyzed with flow cytometry were recognized in fully differentiated 3T3-L1 adipocytes. Treatment with PPARγ ligands, 10 μM Pio and 10 μM 15-deoxy-Δ12,14-prostaglandin J2 increased adipocytes proliferation. In this study, we screened genes regulated by Pio, and we took note of PLF as a growth factor in adipocytes. PLF, also termed mitogen-regulated proteins, is a member of the prolactin/GH family is involved in angiogenesis of placenta. PLF, secreted as a paracrine agent, binds to the insulin-like growth factor II (IGF-II)/cation-independent mannose 6-phosphate (M6P) receptor which can couple with Gi protein. We clarify the role of PLF in adipocytes replication.
Materials and methods: Effects of PLF knockdown with siRNA and treatment with anti-PLF antibody (PLF-Ab) on 3T3-L1 adipocytes were examined. Expression of PLF in adipocytes isolated from rats during treatment with or without Pio was measured. In addition, effect of PLF-Ab administration on adipocytes growth was evaluated.
Results: Treatment with Pio increased PLF mRNA levels and protein levels in cell lysate and medium in 3T3-L1 adipocytes. Both PLF knockdown and an addition of PLF-Ab reduced adipocytes proliferation evaluated by cell number and BrdU incorporation. Treatment with IGF-II enhanced cell proliferation, whereas pertussis toxin suppressed its proliferation. These results indicated that PPARγ-induced PLF positively regulates cell replication in 3T3-L1 adipocytes. and that involvement of IGF-II/cation-independent M6P receptor was also suggested. PLF was more abundantly expressed in visceral adipocytes than subcutaneous ones, while treatment with Pio increased subcutaneous adipocytes, but not visceral ones, which closely correlated to the extent of BrdU incorporation in each adipose tissue. PLF-Ab injection resulted in decreased BrdU incorporation in adipocytes. These results strongly supported the notion that PLF is actually involved in mature adipocyte replication in vivo.
Conclusion: PLF was suggested to be involved in cell replication as a PPARγ-induced growth factor in mature adipocytes.

Mammalian Ste20 kinase stimulates adipogenesis by activation of PPARγ
T. Oh[1], B. Park[2], S. Park[2], Y. Lee[2];
[1]Internal Medicine, Chungbuk National University, Cheongju,
[2]Biochemistry, Chungbuk National University, Cheongju, Republic of Korea.

Background and aims: Recent studies have shown that mammalian ste20 kinase (MST) signaling pathway plays an important role in the regulation of apoptosis and cell cycle control and is thus emerging as a novel tumor suppressor pathway. MST pathway, originally identified as hippo pathway in Drosophila, involves several participating proteins including a scaffolding protein Salvador (SAV1). The idea of MST signaling pathway functioning in cell differentiation seems plausible but needs investigation. Based on our finding that MST2 interacts with PPARγ, a key regulator of adipogenesis, through SAV1, we sought to understand the novel role of the MST signaling pathway in adipocyte differentiation.
Materials and methods: Proteins of interest were overexpressed or knocked down by siRNA in cell cultures of HEK293 cells and 3T3-L1 adipocytes. We employed various protein analysis methods and Oil red staining to analyze the MST signaling pathway.
Results: We found that MST2 bound to PPARγ through SAV1 and stabilized PPARγ protein. Interaction was dependent on the N-terminal portion of SAV1 including WW domains and the N-terminal portion of PPARγ including PPXY motif. We could not find the evidence that PPARγ is a direct substrate of MST2. Coexpression of MST2 and SAV1 resulted in a profound induction of PPARγ activity even in the absence of stimulation by an agonist rosiglitazone. During the differentiation period of 3T3-L1 cells, the protein expression of MST2 and SAV1 showed increases preceding that of PPARγ and the protein complex of endogenous SAV1 and PPARγ could be detected. Finally, adipocyte differentiation of 3T3-L1 cells was increased by overexpression of MST2 and SAV1 while it was decreased by knockdown of SAV1 using siRNA.
Conclusion: From the results, we propose that the activation of PPARγ by the MST signaling pathway may be a novel and important regulatory mechanism of adipocyte differentiation.

Association of human obesity with altered adipose PTX3 gene expression and protein plasma levels

A.M. Gómez-Foix[1], O. Osorio[1], M. Guitart[1], M.R. Chacon[2], E. Maymó-Masip[2], J.M. Moreno[3], M. Montori[1], J.M. Fernández-Real[3], J. Vendrell[2];
[1]Dep. Bioquimica i Biologia Molecular, CIBERDEM, Universitat de Barcelona, [2]Joan XXIII University Hospital, CIBERDEM, Rovira i Virgili University IISPV, Tarragona, [3]Unit of Diabetes, Endocrinology and Nutrition, Hospital de Girona, Spain.

Background and aims: PTX3 is a secreted acute-phase long pentraxin that is believed to mediate innate immunity and inflammation. PTX3 gene is mainly expressed in adipose tissue, and smooth and cardiac muscle in humans. Plasma PTX3 protein concentration has been negatively correlated with human obesity, and positively with atherosclerotic inflammation, and is a risk marker for myocardial infarction. The PTX3 gene expression is stimulated by TNFα and IL-1β in cultured human fibroblasts and endothelial cells. We examine the relationship between plasma PTX3 protein and adipocyte PTX3 gene expression levels with human obesity. We also aim to provide insight into the mechanisms of PTX3 alterations.
Materials and methods: Subjects: Two different cohorts were included in the study. For adipose tissue gene expression, 43 obese and 19 lean age- and gender-matched subjects were selected. A second cohort of 75 apparently healthy men (mean age 50.7 ± 11.2 years) was selected for the study of insulin sensitivity and insulin secretion using the minimal model approach. Methods: Paired subcutaneous (sc) and visceral (v) adipose tissue (AT) biopsies and isolated adipocytes. PTX3 gene expression was assessed by quantitative real time PCR. PTX3 protein plasma levels were measured by ELISA. Human preadipocyte SGBS cell line was differentiated *in vitro* to mature adipocytes and subjected to various stimuli.
Results: A negative correlation between plasma PTX3 protein levels, body weight (r=-0.32, p=0.016) and waist-hip ratio (r=-0.37, p=0.006) was shown. We also found a negative correlation between plasma PTX3 protein and total triglyceride levels (r=-0.33, p=0.004), and insulin secretion after intravenous glucose administration (acute insulin response to glucose) (r=-0.34, p=0.006) and oral glucose administration (measured as serum insulin at 30 minutes of the oral glucose tolerance test) (r=-0.25, p=0.04). Total PTX3 gene expression was similar in vAT and scAT, regardless of obesity. Expression in vAT was significantly lower in non-obese (BMI ≤ 25 Kg/m^2) than in obese (BMI > 25 Kg/m^2) subjects (p=0.039). The PTX3 gene expression was higher in adipocytes isolated from vAT than from scAT (p=0,034). Likewise, in vAT, the PTX3 gene was more strongly expressed in the isolated adipocytes than in the stromovascular fraction (p=0,028). In cultured SGBS adipocytes, PTX3 gene expression was enhanced by TNFα and IL-1β, whereas IL-6, insulin, hypoxia, antimycin A and H_2O_2 had no significant effect.
Conclusion: Plasma PTX3 protein levels correlate negatively with obesity markers and insulin secretion in human subjects. In contrast, the PTX3 gene expression is upregulated in vAT depots of obese subjects and it is enhanced in cultured human adipocytes by proinflammatory cytokines. These data indicate that PTX3 may have a role in the inflammatory process that drives obesity.

Ask1 is regulated in intra-abdominal adipocytes and human fat through combinatorial phosphorylation input and by stress-specific transcriptional regulation

Y. Beck-Haim[1], N. Palgi[1], M. Blüher[2], N. Klöting[2], T. Tarnovscki[1], B. Kirshtein[3], I. Harman-Boehm[4], N. Bashan[1], A. Rudich[1];
[1]Department of Clinical Biochemistry, Ben Gurion University of the Negev, Beer-Sheva, Israel, [2]Department of Medicine, University of Leipzig, Germany, [3]Department of Surgery, Soroka University Medical Center, Beer-Sheva, Israel, [4]Department of Internal Medicine C, Ben Gurion University of the Negev, Beer-Sheva, Israel.

Background and aims: We have recently demonstrated that omental fat in human obesity is associated with a MAP kinase stress signaling pathway involving the MAP3K5 Ask1 in adipocytes. Moreover, Ask1 exhibited both increased levels of the activating phosphorylation site Thr845, and increased protein and mRNA expression, the latter demonstrated as an independent predictor of whole-body insulin sensitivity. Here we aimed at unraveling the molecular basis for the regulation of Ask1 in intra-abdominal adipocytes.
Materials and methods: We utilized novel differentiated depot-specific pre-adipocyte cell lines, which we have demonstrated to retain various depot-specific characteristics to study phosphorylation- and expression mediated regulation of Ask1 by Western blot and qRT-PCR analyses, respectively. Findings were also determined in human omental and subcutaneous (SC) adipose tissue.
Results: Intra-abdominal (IA) adipocytes exhibited larger increase in Thr845 phosphorylation than subcutaneous (SC) adipocytes in response to TNFα. In contrast, TNF-induced phosphorylation on the inhibitory Ser83 site was lower in IA adipocytes and peaked later than the activatory site. Like p-Ser83, Thr966 phosphorylation also peaked later than Thr845 in both cell lines. Ask1 mRNA levels increased approximately 2-fold in response to TNFα (at 4 and 24h), FasL and oxidative stress (at 24h), but no activation was observed with the ER stress inducer tunicamycin. Intriguingly, in human omental compared to SC fat despite elevated p-Thr845, different levels of the inhibitory phosphorylation sites could be observed, suggesting that activity is influenced by a combinatorial phosphorylation input. With regards to gene expression, we assessed members of the E2F family of transcription factors, since they have been implicated in the regulation of Ask1 expression in-vitro. Human omental fat displayed increased mRNA and protein expression of members of the transcription factors members E2F1 and E2F4 in omental versus SC fat, and in obesity compared to lean persons.
Conclusion: Ask1 in intra-abdominal adipocytes may be regulated in a complex manner: i. by a combinatorial input of Ask1 kinases acting on activatory and inhibitory phosphorylation sites. ii. by changes in gene regulation, potentially mediated by changes in E2F family of transcription factors in response to inflammatory and oxidative stress.

TNF-like inducer of apoptosis prevents TNF-alpha-induced insulin resistance in human visceral adipocytes

A. Vazquez-Carballo[1], M.R. Chacon[2], R. Vila-Bedmar[1], M. Lorenzo[1], J. Vendrell[2], S. Fernandez-Veledo[1];
[1]Biochemistry and Molecular Biology II, Complutense University, Madrid, [2]Research Department, Pere Virgili Institute. University Hospital of Tarragona Joan XXIII, Spain.

Background and aims: Insulin resistance is an important contributor to the pathogenesis of type 2 diabetes (T2D) and obesity is a risk factor for its development. In the obese state an altered secretion pattern, with increase in pro-inflammatory and decrease in anti-inflammatory factors is found. In fact, obesity is considered a low-grade inflammatory state. Several mediators released from adipocytes and macrophages, including TNF family members, have been suggested to impair insulin action in peripheral tissues. Tumor necrosis factor-like weak inducer of apoptosis (TWEAK) is a relatively recently identified pro-inflammatory cytokine that regulates multiple cellular responses. Tweak could be involved in the pathogenesis of chronic inflammatory diseases but its physiological role in adipose tissue is still not known. The objective of the present study was to dissect the differential effects of Tweak vs. TNF-α on human visceral adipocytes.
Materials and methods: We analyzed the impact of TNF-α and Tweak on glucose uptake and insulin action in a human visceral adipocytic cell line with high capacity to differentiate.
Results: TNF-α and Tweak activates different intracellular signaling pathways in human visceral adipocytes. In this regard, TNF-α induces insulin resistance by JNK1/2-dependent mechanism, impairing insulin-stimulated glucose uptake and insulin signaling at the insulin receptor substrate (IRS)-1/Akt level. By contrast, Tweak does not induce JNK1/2 activation and in consequence insulin sensitivity on glucose uptake is not affected. Moreover, pre-treatment with Tweak prevented TNF-α-dependent JNK1/2 activation, restoring insulin signaling and insulin-induced glucose uptake.
Conclusion: Tweak shows a protective role against TNF-α-induced insulin resistance in human visceral adipocytes. Our results suggest the balance of TNF family members on adipose tissue as a key factor in the pathogenesis of obesity-associated metabolic disorders.

Adipose reduction in the activity of the repressor ICER is responsible for insulin resistance elicited by the transcriptional factors CREB in obesity

D. Favre[1], E. Legouil[1], C. Verdumo[2], D. Fahmi[1], R. Regazzi[3], P. Vollenweider[1], V. Giusti[2], G. Waeber[1], A. Abderrahmani[1];
[1]Service of Internal Medicine, University Hospital of Lausanne (CHUV), [2]Service of Endocrinology and Diabetotologia, University Hospital of Lausanne (CHUV), [3]Department of Cell Biology and Morphology, University of Lausanne, Switzerland.

Background and aims: Sustained adipose activation of the transcriptional activators cAMP response binding proteins (CREB) in obesity leads to impaired expression of the glucose transporter GLUT4 and adiponectin (adipoq) in mice model of obesity. Diminution of GLUT4 and adipoq caused by CREB is indirect and relies on the increased repressive activity of the CREB target gene activating transcription factor 3 (ATF3). Specific inactivation of CREB in adipocytes decreases ATF3 production and improves whole-body insulin sensitivity of mice in the context of diet-induced obesity. Thus, elevation of CREB activity is a key mechanism responsible for adipocyte dysfunction and systemic insulin resistance. The inducible cAMP early repressor (ICER) is a negative regulator of the CREB activity. In fact, ICER antagonizes the CREB factor by competing for the regulation of similar target genes. The goal of the study was to investigate whether loss of ICER expression in adipocytes could be responsible for increased CREB activity in obesity.
Materials and methods: Mice C57bl6 were fed with a high fat diet (HFD) for 12 weeks to increase body weight and generate insulin resistance. Biopsies of visceral adipose tissues (VAT) were prepared from human lean (BMI=24±0.5 Kg/m2) or obese subjects (BMI>35 Kg/m2). Total RNA and protein were prepared from white adipose tissues (WAT) of chow- or HFD-fed mice and VAT of lean and obese subjects. Activities of CREBs and ICER were monitored by electromobility shift assays (EMSA). The role of ICER on CREB activity was confirmed in 3T3-L1 adipocytes cells. Briefly after differentiation, the cells were electroporated with the plasmid coding for ICER cDNA. Gene expression was quantified by quantitative real-time PCR and western Blotting experiments.
Results: The expression of ICER is reduced in WAT of HFD-induced obese mice when compared to chow mice as measured by real-time PCR and EMSA. Similar result was found in human tissues. Reduction in ICER expression was associated with increased ATF3 expression and decreased adipoq and GLUT4 contents. Diminution in ICER levels was observed in adipocytes fraction whereas its expression was unchanged in stroma vascular fraction of WAT. Overexpression of ICER in 3T3-L1 adipocytes silenced the expression of ATF3, confirming the regulation of the factor by ICER. The expression of ICER is regulated by histone deacetylases activity (HDAC). Inhibition of HDACs in 3T3-L1 adipocytes cells using trichostatin inhibited the production of ICER. The whole activity of HDAC was reduced in WAT and VAT of obese mice and human obese subjects.
Conclusion: Impaired adipose expression of ICER is responsible of increased CREB activity in adipocytes in obesity. This mechanism relies on reduction of the HDAC activity.

IL-1β is a putative mediator in disturbed adipocyte-hepatocyte crosstalk that is induced by adipose inflammation

O. Nov[1], S. Wueest[2], D. Konrad[2], E.C. Lewis[1], I. Dvir[1], S. Fishman[3], N. Bashan[1], A. Rudich[1];
[1]Department of Clincal Biochemistry, Ben Gurion University, Beer Sheva, Israel, [2]Division of Pediatric Endocrinology and Diabetology, University Children's Hospital, Zurich, Switzerland, [3]Department of Gastroenterology and Hepatology, Tel Aviv Sourasky Medical Center, affiliated to Sackler School of Medicine, Israel.

Background and aims: Although the role of IL-1β in (auto)inflammatory cascades is well established, its involvement as an endocrine mediator of adipose tissue-liver crosstalk in obesity is still debated. Here we hypothesized that secreted IL-1β by adipose tissue plays a role in mediating hepatic insulin resistance in response to adipose inflammation.
Materials and methods: We utilized primary rat hepatocytes or human and rat hepatoma cell lines, and tested direct modulation of proximal and distal insulin signalling by IL-1β. In addition, we used conditioned medium from human omental fat explants. Furthermore, we measured systemic and portal IL-1β levels and mRNA expression in different fat depots in mice.
Results: The release of IL-1β from human omental fat explants ranged between 0.15 and 1.5 ng/gr tissue per 24h, and correlated with BMI (R^2=0.639, p<0.01). Human hepatoma cells (HepG2) incubated with omental fat conditioned medium exhibited impaired insulin-stimulated phosphorylation of IR, IRS, PKB and GSK3. This effect has been strongly attenuated (p<0.05) by co-incubation with human recombinant IL-1 receptor antagonist (IL-1Ra). Mice fed high fat diet for 8 weeks (i.e., before marked infiltration by macrophages occur) exhibited no detectable increase in IL-1β mRNA in the systemically-drained peripeipdidymal fat pad, but a 1.8-fold increase in IL-1β expression in portal-drained mesenteric fat. Consistently, whereas no increase in systemic circulating IL-1β levels was observed in these mice, portal blood levels of the cytokine were 2.4-fold elevated (p<0.05). The potential of IL-1β to induce insulin resistance was further demonstrated utilizing rat primary hepatocytes, and in the Fao hepatoma cells could be shown to engage impaired insulin-stimulated tyrosine phosphorylation of both IRS1 and IRS2.
Conclusion: While clear pathophysiological role for IL-1β as a mediator of hepatic insulin resistance in response to adipose inflammation still awaits appropriate in-vivo models, this study provides compelling in-vitro support for this notion. Reported beneficial effects of IL-1Ra or neutralizing anti-IL-1β Ab may therefore prove to be at least partly contributed by interference with a dysfunctional visceral fat-liver communication.

The role of IL-1RI mediated T cell accumulation in adipose tissue - insights to the development of obesity-induced insulin resistance

K.A. Harford[1], C.M. Reynolds[1], F.C. McGillicuddy[1], M. Claessens[1], E. Oliver[1], O. Finucane[1], K.H.G. Mills[2], H.M. Roche[1];
[1]Nutrigenomics, UCD Conway Institute, Dublin, [2]School of Biochemistry and Immunology, Trinity College Dublin, Ireland.

Background and aims: Immune cell infiltration into adipose tissue during high-fat feeding has recently been characterised with T cell recruitment evident prior to macrophage recruitment. Immune cell-derived cytokines are hypothesized to augment adipose tissue inflammation and insulin resistance. Cytotoxic T cells are effector T cells that have been implicated in adipose tissue macrophage differentiation, activation and migration. Helper T cells are a sub-group of T cells involved in the activation and direction of other immune cells. γδ T cell receptor (TCR) expressing cells represent a small subset of T cells that possess a distinct γδ TCR on their surface and play a key role in amplifying the immune response bridging the innate with the adaptive immune system. IL-1 plays a key role in activation of γδ TCR expressing cells and thus in this study we hypothesized that lack of IL-1 signalling may alter T cell subset recruitment into obese adipose tissue, in particular affecting γδ TCR expressing cell recruitment.
Materials and methods: C57BL/6 WT and IL-1RI$^{-/-}$ mice were fed a high-fat diet (HFD) (45 % palm oil) for 16 weeks. At weeks 0, 6, 12 and 16, glucose tolerance tests (GTT) were performed (1.5g/kg glucose, ip) and epididymal

adipose tissue (EAT) was harvested. Adipocytes and stromal vascular cells (SVC) were separated by collagenase treatment. SVC were labelled with antibodies for T cell markers CD3, CD4, CD8 and the γδ T cell receptor (TCR) and analysed by flow cytometry. $CD3^+CD4^-CD8^+$ cells are cytotoxic T cells while $CD3^+CD4^+CD8^-$ cells represent helper T cells. Cells expressing the γδ TCR were also determined. Results presented as percentage total SVC.
Results: IL-$1RI^{-/-}$ mice exhibited a more glucose tolerant phenotype at baseline and after 12 and 16 weeks on HFD. Development of obesity was associated with a steady rise in the number of cytotoxic T cells ($CD3^+CD4^-CD8^+$) in adipose tissue of WT mice after 6 (from 0.06±0.02% to 2.45±0.3%) and 12 (6.57±1.2%) weeks of high-fat feeding ($p<0.001$), with no difference between WT and IL-$1RI^{-/-}$ genotypes. The population of helper T cells ($CD3^+CD4^+CD8^-$) remained low throughout with significantly higher levels observed in WT mice at week 16 compared to IL-$1RI^{-/-}$ (5.8±0.7% vs 2.8±0.9%) ($p<0.001$). Interestingly the number of γδ TCR expressing cells recruited into adipose tissue during HFD was much higher (19.3±1.5% at week 12) than other T cell subsets. Further, there was significantly less in the IL-$1RI^{-/-}$ mice compared to WT after 12 (19.3±1.5% vs 15.3±1.0%) and 16 (13.4±0.7% vs 9.5±1.4%) weeks of high-fat feeding ($p<0.05$) consistent with an important role for IL-1 in activation of γδ TCR expressing cells.
Conclusion: In the present study we demonstrate that during obesity both cytotoxic T cells and γδ TCR expressing cells infiltrate adipose tissue and thus may play a crucial role in initiating the inflammatory response and recruiting adipose tissue macrophages. Further, IL-1 plays a key role in mediating infiltration of γδ TCR expressing cells into adipose tissue but does not affect recruitment of other T-cell subsets. Reduced recruitment of γδ TCR expressing cells into adipose tissue of IL-$1RI^{-/-}$ mice may in turn partially account for protection from HFD-induced insulin resistance.

Human adipose tissue macrophage activation and impairment of adipocyte functions by osteopontin
M. Zeyda[1], K. Gollinger[1], J. Todoric[1], O. Aszmann[2], G. Prager[2], T.M. Stulnig[1];
[1]Dept. of Medicine III, [2]Dept. of Surgery, Medical University of Vienna, Austria.

Background and aims: Osteopontin (OPN) is highly upregulated in adipose tissue in human and murine obesity and has been recently shown to be functionally involved in the pathogenesis of obesity-induced adipose tissue inflammation and associated insulin resistance in mice. OPN is a protein with multiple functions and acts as a chemokine and an inflammatory cytokine through a variety of different receptors (CD44, integrins). It is expressed in many cell types including adipose tissue macrophages (ATM). However, the target cells of OPN action in obese adipose tissue are still elusive. Here, we investigated expression of OPN receptors and the impact of OPN on ATM, adipocytes and other cells of human adipose tissue.
Materials and methods: Receptor expression was assessed by immunostaining of human omental adipose tissue sections and mRNA expression in fractionated subcutaneous adipose tissue. Human in vitro differentiated macrophages and primary adipose tissue macrophages isolated by flow-cytometry were stimulated with OPN. Human adipocytes differentiated from primary preadipocytes were pretreated or not with OPN prior to insulin stimulation.
Results: We found broad expression of OPN receptors in different adipose tissue cell types including adipocytes. OPN stimulated phosphorylation of Akt and MAP kinases, degradation of IκB-α, as well as secretion of Mcp-1, TNFα, and IL-10 in model macrophages and isolated human ATM. Moreover, OPN impaired differentiation and function of primary adipocytes as determined by PPARγ and adiponectin gene expression and insulin-stimulated glucose uptake.
Conclusion: OPN activates adipose tissue macrophages and interferes with adipocyte function thereby underlining the potential use of OPN as a therapeutic target for obesity-induced complications.

High-fat diet induced insulin resistance triggers infiltration of dendritic cells into adipose tissue and primes the inflammatory response of bone marrow dendritic cells
C.M. Reynolds[1], F.C. McGillicuddy[1], K.A. Harford[1], K.H.G. Mills[2], H.M. Roche[1];
[1]Conway Institute, University College Dublin, [2]Immune Regulation Research Group, Trinity College Dublin, Ireland.

Background and aims: Dendritic cells (DC) provide the first line of defence against invading pathogens and play a key role in facilitating cross-talk between the innate and adaptive immune systems. High-fat diet (HFD) induced obesity and insulin resistance (IR) is associated with a heightened inflammatory state and infiltration of macrophages and T-cells into adipose tissue. In this study we hypothesized that a HFD would result in recruitment of DC into adipose tissue, activate the DC immune response, with functional effects on adipocyte insulin sensitivity.
Materials and methods: C57BL/6J mice were fed a HFD (45% palm oil) for 16 weeks, glucose tolerance was monitored pre- and post-HFD. Stromal vascular fraction (SVF) cells were isolated from adipose and analyzed by flow cytometry for $CD11c^+CD11b^+F480^-$ DC. Bone-marrow DC (BMDC) were isolated and stimulated ± LPS (100ng/ml) for 24h and cytokine release measured by ELISA. To characterize the effects of DC on adipocyte biology 3T3-L1 adipocytes were co-cultured with DC (± LPS stimulation), then insulin-stimulated ^{3}H-glucose uptake and insulin signaling was monitored.
Results: Mice developed overt insulin resistance after 16 wks HFD with marked delay in clearance of plasma glucose during GTT compared with chow-fed and week 0 control mice. DC infiltration into adipose tissue was evident after high fat feeding. BMDC derived from HFD-fed mice exhibited a much more pronounced inflammatory response, with greater IL-12p70, IL-10, and IL-1β secretion, in response to LPS compared to age-matched chow-fed control cells. BMDC TLR4 mRNA and protein expression was enhanced in these cells pre-LPS stimulation. Co-culture of BMDC with 3T3L1 adipocytes induced marked insulin resistance in adipocytes with marked reduction in insulin-stimulated ^{3}H-glucose uptake.
Conclusion: HFD induces IR which is associated with infiltration of DC into adipose. BMDC from these HFD fed animals are primed to be more responsive to inflammatory stimuli and can block insulin mediated glucose uptake in adipocytes.

Inflammatory adipocyte activation by heat shock protein 60 involves MAP-kinase- and NFkB-dependent signalling pathways
V. Burkart, J. Kriebel, T. Märker, C. Habich;
Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Adipocytes and their mediators have been recognized to play central roles in the development of the metabolic syndrome and in the pathogenesis of diabetes. Recent studies in the New Zealand obese (NZO) mouse, an animal model of the metabolic syndrome, identified heat shock protein 60 (Hsp60) as an endogenous stress signal with pronounced adipocyte stimulating capacity. Hsp60 was found to induce the release of proinflammatory cytokines and chemokines from adipocytes in a receptor-mediated process. With regard to the development of intervention strategies aiming at the modulation of adipocyte-driven proinflammatory processes, our present study was designed to identify key components of signalling pathways involved in the Hsp60-induced release of inflammatory adipocyte mediators.
Materials and methods: Hsp60-mediated activation (phosphorylation) of MAP-kinase family members (p38, ERK1/2, JNK) and of the transcription factor NFκB was analysed by immunoblotting lysates of primary NZO mouse-derived preadipocytes and mature adipocytes. The potential contribution of these signalling molecules to the Hsp60-induced release of the inflammatory mediators IL-6, KC and MCP-1 was assessed by applying specific inhibitors and the use of multiplex beads analyses.
Results: We could demonstrate for the first time that the stress protein Hsp60 activates members of the MAP-kinase family and the transcription factor NFkB in primary adipocytes of the NZO mouse. Hsp60 exposure (10 μg/ml) slightly activated ERK1/2 phosphorylation in mature adipocytes (1.4±0.4-fold), but not in preadipocytes. JNK was weakly activated in mature

adipocytes as well as in preadipocytes up to 2.2±1.2-fold. No Hsp60-induced activation of p38 was observed in the cells. NFkB activation was significantly increased (up to 2.6±0.9-fold) in Hsp60 exposed adipocytes independent of their maturation state ($p<0.05$). The ERK1/2-inhibitor PD98059 suppressed the release of the inflammatory mediator MCP-1 depending on the maturation state of the adipocytes. In preadipocytes the MCP-1 release was slightly decreased in a dose-dependent manner from 5.3±2.0 ng/ml to 3.6±1.4 ng/ml (inhibition by 22.1%), whereas in mature adipocytes the MCP-1 release was strongly reduced from 8.3±5.1 ng/ml to 1.9±2.3 ng/ml (inhibition up to 80.8%, $p<0.001$). The release of IL-6 and KC was not affected by the inhibitory drug. Selective inhibition of JNK by SP600125 caused a weak inhibition of KC-release from mature adipocytes and of MCP-1 release from preadipocytes and mature adipocytes. Inhibition of NFkB activation by SN50 resulted in a strong, dose-dependent reduction of the release of IL-6 (up to 99.9% inhibition, $p<0.001$), KC (up to 91.8% inhibition, $p<0.001$) and MCP-1 (up to 94.1% inhibition, $p<0.01$) from adipocytes independent of their maturation state.

Conclusion: The results of our study point to the involvement of different signalling pathways in the proinflammatory activation of NZO mouse-derived adipocytes by Hsp60. Whereas ERK1/2 and JNK are differentially activated depending on the adipocyte maturation state, NFκB activation is largely independent of the maturation state of the cells. Our findings will contribute to identify components of the intracellular signalling cascades as potential targets for the modulation of diabetes-associated inflammatory adipocyte activities induced by endogenous stress signals.

Short chain fatty acid regulation of inflammatory response in human primary macrophages

O. Pivovarova[1,2], S. Weimer[1], A.F.H. Pfeiffer[1,2];
[1]Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, [2]Department of Endocrinology, Diabetes and Nutrition, CBF, Charité University Medicine, Berlin, Germany.

Background and aims: Insulin resistance in adiposity and type 2 diabetes is associated with low grade system inflammation characterized by macrophage infiltration of adipose tissue. Short chain fatty acids (SCFA) produced by intestinal microbiota modulate inflammatory responses. This effect have been demonstrated in various immune cells (neutrophiles, monocytes, PBMC fraction), tumor cell lines, tissue culture and animal studies, but not in mature human macrophages. The aim of this study was to investigate SCFA effects on the cytokine expression in human primary macrophages of proinflammatory M1- and antiinflammatory M2-subtypes.

Materials and methods: For the culture of human primary macrophages, monocytes were isolated from the whole blood and differentiated in RPMI medium supplemented with 50 ng/ml GM-CSF (M1-macrophages) or M-CSF (M2-macrophages) and 10% foetal bovine serum for 7 days. For the experiment, mature cells were incubated in the medium with acetate or propionate (2, 20 mM) for two hours with following LPS treatment (100 ng/ml) for 22 hours. The expression of cytokines (MCP1, IL-1β, IL-6, IL-8, IL-10, TNF-α) and SCFA receptors was assessed by quantitative real-time PCR.

Results: The low level of mRNA expression of SCFA receptors GPR41 and GPR43 activated by acetate and propionate was detected in both studied subtypes of human primary macrophages. Interestingly, LPS treatment significantly increased the expression of both receptors with this effect being more apparent in M2-macrophages (219-fold for GPR41 and 46-fold for GPR43). Acetate (20 mM) and propionate (2, 20 mM) treatment considerably attenuated LPS-induced receptor expression. SCFA effects on the basal and LPS-induced cytokine expression were studied. Propionate at high concentration (20 mM) corresponding to the concentration in human colon demonstrates antiinflammatory effect due to significantly decrease of the LPS-induced cytokine expression. Interestingly, the same propionate treatment increased cytokine expression in macrophages incubated without LPS stumulation. These effects were detected both in M1- and in M2-cell subtypes. For acetate, no influence on the cytokine expression was found.

Conclusion: Propionate demonstrates modulatory effects on the inflammatory response in the culture of human primary macrophages which are possibly mediated by metabolic, rather than receptor-coupled mechanism. Thus, propionate produced by intestinal microbiota may contribute to the regulation of inflammatory responses of tissue macrophages in adiposity and type 2 diabetes.

Acute and chronic saturated fatty acid treatment as a key instigator of the TLR mediated inflammatory response in human adipose tissue *in vitro*

A.L. Harte[1], E.M. Youssef-Elabd[2], K.C. McGee[1], G. Tripathi[1], M.S. Abdalla[3], H.M. Sharada[3], E. Ashour[2], A.I. Amin[4], J.P. O'Hare[1], S. Kumar[1], P.G. McTernan[1];
[1]Unit for Diabetes and Metabolism, University of Warwick, United Kingdom, [2]Biochemistry Dept, National Research Centre, Dokki, Giza, Egypt, [3]Chemistry Dept, Helwan University, Egypt, [4]Clinical Pathology Dept, National Institute of Diabetes & Endocrinology, Cairo, Egypt.

Background and aims: Chronic elevation of saturated fatty acids (SFAs) and glucose (Glc) appears to activate an inflammatory response; compounded by habitual feeding. Restoration of physiological SFAs and Glc levels postprandially may not attenuate the original insult; a concept termed 'metabolic memory'. Therefore we investigated (1) the effect of chronic and oscillating SFAs and Glc on the inflammatory pathway in human abdominal subcutaneous (AbdSc) adipose tissue (AT) and adipocytes (Ads) (2) whether there is a sustained inflammatory response in absence of treatment.

Materials and methods: AbdSc AT (age 45±3.3 yrs; BMI: 21.9±2.4 kg/m^2; n=6) was obtained with ethics approval. Explants and Ads were treated with chronic low glucose (L-Glc): 5.6mM and high glucose (H-Glc): 7.5mM, with low (0.2 mM) and high (2 mM) doses of a palmitate:stearic tri-mix (SFA) for 48 hrs. Further, AbdSc AT explants and Ads were also exposed to the aforementioned treatment regimen for 12hr periods, with alternating rest periods of 12hr in L-Glc. Western blot and ELISAs were utilised to examine components of the NFκB pathway.

Results: Chronic treatment with H-Glc and high SFAs up-regulated key proteins of the NFκB pathway in AbdSc AT explants and Ads (TLR4, NFκB, $p<0.05$) whilst down-regulating MyD88 protein levels. Oscillating treatment with Glc and SFAs increased TLR4, NFκB, IKKβ and MYD88 in explants and Ads ($p<0.05$). Downstream TNFα and IL-6 ($p<0.05$) secretion were markedly increased in chronically treated explants and Ads whilst, with oscillating treatments, a sustained inflammatory effect was noted in absence of treatment.

Conclusion: In summary, this study implicates elevated SFAs as a key instigator of the inflammatory response in both AT and Ads, via NFκB, and suggests that short-term exposure of cells to uncontrolled levels of SFAs and Glc leads to a longer-term inflammatory insult within the Ads. As such, these findings highlight a potential molecular mechanism linking high SFA dietary intake and an adverse inflammatory response in patients with obesity and T2DM.

Distinct gene expression and cytokine release profiles identify three different adipose tissue progenitor cells in human abdominal subcutaneous and visceral adipose tissue

S. Perrini, R. Ficarella, A. Cignarelli, A. Peschechera, M. Barbaro, P. Nigro, A. Conserva, M.C. Carreira, A. Natalicchio, L. Laviola, F. Giorgino;
Endocrinology & Metabolic Diseases, D.E.T.O., University of Bari, Italy.

Background and aims: Adipose-derived stem cells (ASCs) can be isolated from the stromal-vascular fraction (SVF) of adipose tissue (AT) (ASC-SVF). ASCs can be also isolated both from a pre-adipocyte fraction present in the fat cake at the top of the supernatant not previously collected together with the ASC-SVF (ASC-B), and from mature adipocytes through in vitro de-differentiation (ASC-C). The aim of this study was to investigate the biological features of these three different ASCs.

Materials and methods: All ASCs were isolated from paired abdominal subcutaneous (SC) and visceral (V) AT biopsies obtained from 16 subjects (8F/8M, age 65±1 yrs, BMI 24.9±1.4). A genome-wide differential gene expression analysis followed by quantitative RT-PCR was performed on each SC and V ASC population. Cytokine secretion was analyzed by Bioplex protein array of the ASC conditioned medium.

Results: The six distinct ASCs were positive for the adipogenic lineage markers CD105, CD44, and CD49d, and were able to differentiate into adipocytes, chondrocytes, and osteocytes, respectively. To investigate whether ASC-SVF, ASC-B and ASC-C from SC and V fat depots were homogenous or genetically heterogeneous, a genome-wide analysis was performed using a GeneChip Gene 1.0 ST array with 764,885 probe sets, representing 28,869 annotated genes. Of these, we identified 367 and 984 genes that differed among ASC-SVF, ASC-B and ASC-C in SC and V, respectively. These genes were identi-

fied by first testing for significant differences among all ASCs in the 764,885 probe sets with sequence-specific hybridization in at least one sample (Bayesian ANOVA with a P value <0.05). A secondary filter was applied to those genes that resulted significantly different, to identify the genes that varied by at least 1.4-fold among V and SC ASCs. In SC ASCs, of the 367 genes, 169 were found to have a conjoint differential expression in ASC-SVF, ASC-B and ASC-C, while 16, 76 and 106 were the genes that resulted to be differentially expressed in each subset of ASC, respectively. In addition, no gene was found to have a conjoint differential expression in SC ASC-SVF, ASC-B and ASC-C. In V ASCs, 984 genes were found to be differently expressed among ASC-SVF, ASC-B and ASC-C. Of these, 230 genes were found to have a conjoint differential expression in each V ASC population, while 235, 426 and 89 were the genes that resulted to be differentially expressed in each subset of ASC, respectively. In addition, 4 genes resulted to have a conjoint differential expression in all V ASCs. Both in SC and V ASCs, hierarchical clusters identified the presence of large contiguous color patches representing groups of genes that shared a similar expression pattern over multiple conditions both in ASC-SVF and ASC-C, while highly dissimilar was the gene expression pattern in ASC-B compared to ASC-SVF and ASC-C. Of the 26 cytokines measured, IL-6 was secreted at higher levels in SC ASC-C compared to SC ASC-SVF and ASC-B ($p<0.01$), while it was significantly lower in SC ASC-SVF and ASC-B than in V ASCs ($p<0.01$). Secretion of IL-8, VEGF and MCP-1 was also significantly different among the 6 SC and V ASCs.
Conclusion: These results demonstrate the existence of genetically heterogeneous fat-derived populations of progenitor cells, which may add to the complexity and specificity of SC and V AT in humans.

Plasma glucose levels are associated with gene expression levels in subcutaneous and visceral adipose tissue of morbidly obese individuals
M.G.M. Wolfs[1], E.J. Bruin[1], S.S. Rensen[2], J.W. Greve[2], W.A. Buurman[2], T.W. Van Haeften[1,3], C. Wijmenga[4], L. Franke[4,5], M.H. Hofker[1];
[1]Department of Pathology and Medical Biology, Medical Biology Section, Molecular Genetics, University Medical Center Groningen, Netherlands, [2]Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Department of General Surgery, Maastricht University Medical Center, Netherlands, [3]Department of Internal Medicine, University Medical Center Utrecht, Netherlands, [4]Department of Genetics, University Medical Center Groningen, Netherlands, [5]Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry, United Kingdom.

Background and aims: Morbid obesity (BMI>35) dramatically increases the risk to develop type 2 diabetes. The biological mechanisms that drive this increased risk are largely unclear. In this study we aimed to identify genes that are differentially expressed in subcutaneous and visceral adipose tissue of diabetic and non-diabetic obese individuals in order to get insight in the pathologic changes related to diabetes.
Materials and methods: We determined whole-transcriptome gene expression levels in subcutaneous adipose tissue and visceral adipose tissue of 70 morbidly obese individuals by using microarrays (Illumina HumanHT12 BeadChips). From these data we extracted modules of highly coexpressed genes and we tested for each tissue whether these modules correlate with traits that are relevant to diabetes (plasma levels of glucose, insulin, and HbA1c). These modules are driven by the phenotypic differences in our study group, which range from metabolically normal to diabetic.
Results: In both tissues we detected several modules of highly coexpressed genes. Gene Set Enrichment Analysis of the genes within all separate modules showed that the genes within most modules are functionally related. This indicates that our approach yields a biologically meaningful gene classification. Assessment of the correlation between each module and metabolic traits related to diabetes, revealed that in subcutaneous adipose tissue one module is significantly negatively correlated to plasma glucose levels ($p = 7.0 \times 10^{-6}$). This module consists of 28 genes of which most are involved in metabolism. In visceral adipose tissue one module - consisting of 103 genes - is significantly correlated to plasma glucose levels ($p = 2.1 \times 10^{-5}$). Some genes that constitute this module were recently reported to be specifically expressed in macrophages, and are highly enriched in genes related to innate immunity (GO-terms).
Conclusion: In both subcutaneous and visceral adipose tissue we identified several genes that have expression levels which are correlated with plasma glucose levels. In subcutaneous adipose tissue expression levels of a set of metabolic genes were inversely correlated with plasma glucose levels. In visceral adipose tissue a set of genes related to innate immunity were positively correlated to plasma glucose levels. In particular, these genes play a role in the complement system (C1QA, C1QB, C1QC, C3AR1), Toll-like receptor signaling (TLR7, CD14), inflammasome (PYCARD), autophagy (ATG7), and lysosomal function (CTSB, CTSC, CTSZ, FUCA1, GUSB, LGMN). In conclusion, our data indicate that both metabolic and innate immunity related processes in subcutaneous and visceral adipose tissue, bridge the gap between diabetes and obesity.

Effect of hyperinsulinaemia on selected plasma and subcutaneous adipokines during angiotensin II type 1 receptor inhibition in patients with impaired fasting glucose
P. Wohl, E. Švehlíková, S. Kratochvílová, M. Klementová, J. Kopecký Jr., T. Pelikánová;
Diabetes center, IKEM, Prague, Czech Republic.

Background and aims: Only a few studies have investigated the in vivo effect of insulin on adipokines during angiotensin II type 1 receptor inhibition. The aim of our study was to test the effect of insulin on selected plasma and subcutaneous adipokines and their insulin-stimulated changes during telmisartan administration.
Materials and methods: 12 patients with impaired fasting glucose were enrolled in randomized, placebo-controlled, cross-over study of 3 weeks treatment with telmisartan (T) (160 mg/d) or placebo (P). Acute hyperinsulinemia has been induced by one-step hyperinsulinemic euglycemic clamp (120 minutes; 1 $mU.kg^{-1}.min^{-1}$, 5 mmol/l) conducted at the end of each treatment period. Before and during the clamp (0, 30, 120 minutes) plasma levels of adiponectin, resistin, tumor necrosis factor-alfa (TNF) and leptin were measured and needle biopsy of abdominal subcutaneous adipose tissue (SAT; 0, 30 minutes) was performed to evaluate their expressions by the real-time PCR.
Results: Hyperinsulinemia did not affect plasma TNF, but decreased TNF expression ($p<0.001$). Plasma adiponectin concentrations and SAT expression of adiponectin did not changed during insulin-stimulated conditions. Hyperinsulinemia did not change plasma leptin concentrations, but the decrease in leptin expression in SAT was found ($p<0.001$). Plasma resistin rise during hyperinsulinemia ($p<0.001$), while the drop in resistin expression was observed ($p<0.01$). Telmisartan decreased plasma TNF ($p<0.05$) and increased plasma leptin ($p<0.01$) and resistin ($p<0.001$) as compared to P. Moreover, telmisartan increased the plasma adiponectin ($p<0.05$), leptin ($p<0.05$) and resistin ($p<0.01$) concentrations during hyperinsulinemia.
Conclusion: Acute hyperinsulinemia increases plasma resistin concentrations and decreases resistin, leptin and TNF expressions in SAT. Telmisartan decreases plasma TNF and increases plasma leptin and resistin concentrations and changes the effects of insulin on plasma adiponectin, leptin and resistin concentrations. Our results support the hypothesis that telmisartan might play the beneficial metabolic role in patients with impaired fasting glucose.

Absence of the NLRP-3 inflammasome protects against the development of obesity and insulin resistance

R. Stienstra[1,2], J.A. van Diepen[3], C.J. Tack[1], P.C.N. Rensen[3], L.A.B. Joosten[1], M.G. Netea[1], T. Devi Kanneganti[2];
[1]General Internal Medicine, Nijmegen, Netherlands, [2]Department of Immunology, St Jude Children's Research Hospital, Memphis, USA, [3]Department of Internal Medicine, Endocrinology and Metabolic Diseases, Leiden University Medical Center, Netherlands.

Background and aims: The innate immune system is part of the host defence and responds to invading pathogens by inducing an inflammatory reaction. Recognition of pathogens depends on PRRs that are present both on the outer membrane and intracellular components. The nucleotide-binding and oligomerization domain (NOD)-like receptor (NLR) protein NLRP3 responds to microbial ligands and endogenous danger signals present in the cytosol and triggers the formation of a protein complex including the eminent adaptor molecule ASC. The protein complex is named the NLRP-3 inflammasome and, upon formation, it enables the activation of Caspase-1, a cysteine protease that controls release of the pro-inflammatory cytokines IL-1β and IL-18. Obesity is characterized by elevated secretion of numerous cytokines including IL-1β and IL-18 that contribute to the development of insulin resistance and type 2 diabetes. Previously we have shown that Caspase-1 is activated in adipose tissue of obese and insulin resistant animals, which suggests that the innate immune system is involved in the development of metabolic abnormalities associated with obesity. In the present study we tested whether (NLRP-3) inflammasome-dependent Caspase-1 activation mediates high fat diet-induced obesity and insulin resistance.
Materials and methods: To induce obesity and insulin resistance, Wildtype (Wt), NLRP3-/-, ASC-/- and Caspase-1-/- animals were fed a high fat diet (HFD) or low fat diet (LFD) for 16 weeks.
Results: Despite a similar daily food intake, HFD-fed NLRP3-/-, ASC-/- and Caspase-1-/- animals were protected against the development of high fat diet induced obesity**.** Whereas HFD-feeding of wildtype mice led to significantly elevated plasma insulin, leptin and resistin levels, animals lacking the NLRP3-inflammasome were protected against the harmful effects of chronic overfeeding. Importantly, ASC-/- and Caspase-1-/- animals were resistant to the development of high-fat diet induced insulin resistance. In addition to a decrease in total adipose tissue mass, adipocyte cell size was reduced in HFD-fed ASC-/- and Caspase-1-/- animals compared to Wt mice. Detailed analysis of HFD-fed Caspase-1-/- mice using immunohistochemical localization of adipose tissue-resident macrophages revealed a robust reduction of macrophage influx into the adipose tissue. Using microarray analyses of white adipose tissue from HFD-fed Wt vs. Caspase-1-/- animals, we established that over 500 genes involved in immune response, signal transduction and chemotaxis were differentially expressed. Finally, metabolic cage studies of HFD-fed Wt and Caspase-1-/- animals revealed an enhancement in total energy expenditure in the absence of Caspase-1.
Conclusion: Our results show that NLRP-3 inflammasome-mediated caspase-1 activity is involved in the development of obesity, insulin sensitivity, adipogenic gene expression and energy expenditure during chronic overfeeding and suggest that inhibition of inflammasome-dependent caspase-1 activation may be a useful therapeutic strategy for treatment of obesity-induced insulin resistance.

Deletion of macrophage migration inhibitory factor promotes obesity-associated insulin resistance while attenuating inflammation in mice fed a high-fat diet

I. Stojanović[1], T. Cvjetićanin[1], S. Sandler[2], S. Stošić-Grujičić[1];
[1]Immunology, Institute for Biological Research "Siniša Stanković", Belgrade, Serbia, [2]Medical Cell Biology, Biomedical Centre, Uppsala University, Sweden.

Background and aims: Macrophage migration inhibitory factor (MIF) is a multifunctional molecule generally described as pro-inflammatory and glucocorticoid-induced regulator involved in both innate and adaptive immunity. MIF is produced by various immune and non-immune cells including pancreatic β cells. Elevated MIF concentration and MIF mRNA expression was found in the mononuclear cells of obese individuals and serum MIF concentrations are highly increased in individuals with impaired glucose tolerance and type 2 diabetes. Furthermore, an increased expression of MIF mRNA and its protein in pancreatic islets isolated from high-fat diet (HFD)-fed C57BL/6 mice (B6) compared to control diet (CD)-fed mice has been seen (unpublished). Also, increased MIF levels were found in serum of starved animals on HFD. Since obesity is characterized as a state of low grade inflammation, the aim of this study was to investigate the effect of *mif* gene deletion on development of obesity, insulin resistance and inflammatory state in HFD-fed mice.
Materials and methods: Knock-out mice for *mif* gene (MIF-KO) and their wild type counterparts B6 mice were fed a HFD containing 60% fat and control groups were fed a control diet (CD - 10% fat). The weight of mice was measured weekly, triglyceride levels in non-fasting mice were determined spectrophotometrically, while serum markers of inflammation and insulin were measured by ELISA. Glucose and insulin tolerance tests were performed on fasting animals by intraperitoneal injection of D-glucose (2 mg/g b.w) or insulin (0.75 mU/g), respectively. Glucose concentration was determined from blood drawn from tail vein by Glucometer.
Results: Even on standard chow MIF-KO mice gained more weight than B6 mice on the same diet. Furthermore, body mass increment of MIF-KO on HFD was higher compared to HFD-fed B6 mice. As for triglyceride levels, they were similar between MIF-KO and B6 when mice were on CD. Interestingly, although MIF-KO on HFD diet weighed more then B6 on the same diet, their triglycerides were lower, at least at some time points tested. On the other hand, leptin levels corresponded to the weight increase of HFD-fed MIF-KO. Similar values of hyperglycemia were found in both HFD-fed B6 and MIF-KO mice. Although MIF-KO mice on CD were euglycemic, they showed slightly impaired glucose and insulin tolerance. Moreover, marked insulin resistance (judged by both glucose and insulin tolerance test) was evident in HFD-fed MIF-KO mice and was significantly altered compared to B6 mice on HFD. Serum insulin in MIF-KO on HFD was higher compared to CD-fed mice and similar to B6 mice on HFD. Finally, at the end of observation period (11 weeks), inflammatory markers such as CRP and IL-6 were down-regulated in HFD-fed MIF-KO compared to B6, while anti-inflammatory cytokine TGF-β was moderately increased.
Conclusion: These results implicate that *in vivo* MIF deletion exacerbates obesity-induced insulin resistance, but reduces an underlying inflammation during high nutrient intake.

Expression of human chemerin induces insulin resistance in the skeletal muscle but does not affect weight, lipid levels and atherosclerosis in LDL receptor knockout mice on high fat diet

U.C. Brödl[1], M. Becker[1], K. Rabe[1], C. Lebherz[2], J. Zugwurst[1], B. Göke[1], K.G. Parhofer[1], M. Lehrke[1];
[1]Department of Internal Medicine II, [2]Department of Internal Medicine I, University of Munich, Germany.

Background and aims: Chemerin is a recently discovered hepatoadipokine that regulates adipocyte differentiation as well as chemotaxis and activation of dendritic cells and macrophages. Chemerin was reported to modulate insulin sensitivity in adipocytes and skeletal muscle cells *in vitro*. In humans, chemerin was shown to be associated with multiple components of the metabolic syndrome including body mass index, triglycerides, HDL-cholesterol and hypertension. So far, however, the effect of chemerin on these various metabolic parameters has not been studied *in vivo*.
Materials and methods: To investigate the effect of chemerin on weight, glucose and lipid metabolism as well as atherosclerosis *in vivo*, we used recombinant adeno-associated virus to express human chemerin in LDL receptor knockout mice on high fat diet.
Results: Expression of chemerin did not significantly alter weight, lipid levels, and extent of atherosclerosis. Chemerin, however, significantly increased glucose levels during both intraperitoneal glucose tolerance test and insulin tolerance test. Chemerin reduced insulinstimulated Akt1 phosphorylation and activation of 5´AMP activated protein kinase (AMPK) in the skeletal muscle, but had no effect on insulin signaling and AMPK activation in the liver and gonadal adipose tissue.
Conclusion: Chemerin induces insulin resistance in the skeletal muscle *in vivo*. Chemerin is involved in the cross talk between liver, adipose tissue and skeletal muscle.

813

Adipose tissue-specific activation of polyamine catabolism improves energy homeostasis in mice

T.E. Koponen[1], E. Pirinen[1], A. Uimari[1], S. Vuohelainen[1], S. Pirnes-Karhu[1], E. Hohtola[2], M. Laakso[3], L. Alhonen[1];
[1]A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, [2]Department of Biology, University of Oulu, [3]Department of Clinical Medicine, University of Eastern Finland, Kuopio, Finland.

Background and aims: Polyamines are cationic and water-soluble compounds found in all eukaryotic cells. A well-known function of polyamines is their ability to promote cell growth but all their functions are not known. Our previous study in transgenic mice having whole-body overexpression of the key enzyme in polyamine catabolism, spermidine/spermine-N^1-acetyltransferase (SSAT), showed that enhanced polyamine catabolism regulates glucose and energy metabolism. The aim of this study was to investigate the effect of adipose tissue-specific activation of polyamine catabolism on glucose and energy metabolism in mice.
Materials and methods: We generated a transgenic mouse line (aP2-SSAT mice) overexpressing SSAT under an adipose tissue specific aP2 promoter. The SSAT activity was analyzed in a reaction where [14C]-acetyl-CoA was incorporated into polyamines. Basal metabolic rate was determined by indirect calorimetry. Both aP2-SSAT and wild type mice were challenged with high-fat diet providing 42 % calories from fat for three months. AMPK (AMP kinase) and PGC-1 α (peroxisome proliferator-activated receptor γ co-activator 1 α) levels in WAT were determined by western blotting. Glucose metabolism in wild type (wt) and transgenic (tg) mice was studied using intraperitoneal glucose and insulin tolerance tests (GTT and ITT). Plasma glucose levels were determined microfluorometrically and plasma insulin levels with a commercial insulin kit.
Results: SSAT enzyme activity was significantly higher in white (wt: 0.19 ± 0.03 vs. tg: 17.69 ± 2.42 pmol/μg DNA/10 min, p<0.0001) and brown (wt: 0.08 ± 0.05 vs. tg: 1.84 ± 0.46 pmol/μg DNA/10 min, p<0.005) adipose tissues in aP2-SSAT mice than in wt mice. aP2-SSAT mice had significantly reduced perigonadal WAT mass (wt: 2.28 ± 0.16 vs. tg: 1.65 ± 0.15 % of body weight, p<0.005), and white adipocytes had an increased amount of mitochondria. In addition, aP2-SSAT mice had significantly greater oxygen consumption in comparison with wt mice (wt: 1.81 ± 0.05 vs. tg: 2.02 ± 0.06 VO_2 ml/min/100g, p<0.05) implicating that energy expenditure is enhanced in aP2-SSAT mice. When challenged with high-fat diet (HFD), aP2-SSAT mice were resistant to HFD-induced body weight gain (wt control vs. wt HFD body weight p<0.005; tg control vs. tg HFD body weight p>0.05). These findings were explained by increased protein levels of the key regulators of energy metabolism, PGC-1α (wt: 0.68 ± 0.27 vs. tg: 1.86 ± 0.22, p<0.05) and AMPK (wt: 0.94 ± 0.17 vs. tg 1.94 ± 0.25) in WAT of aP2-SSAT mice. Based on glucose and insulin tolerance tests, no changes in glucose metabolism were observed (GTT; wt: 1123.00 ± 114.00 vs. tg: 1237.00 ± 69.48 area under the curve for plasma glucose, p>0.05; GTT; wt vs. tg plasma insulin levels p>0.05 and ITT; wt vs. tg relative glucose levels p>0.05).
Conclusion: Our results suggest that adipose tissue-specific activation of polyamine catabolism does not improve glucose homeostasis but causes beneficial changes in energy metabolism.

Anti-diabetic effect of sodium tungstate in IRS2-deficient mice model

J. Oliveira[1,2], S. Rebuffat[1,2], A. Garcia[1,2], R. Gomis[1,2];
[1]IDIBAPS, [2]CIBERDEM, Barcelona, Spain.

Background and aims: The insulin receptor substrate-2 (IRS2) branch of the insulin/IGF signalling mediates peripheral insulin action and plays an essential role in pancreatic β-cell function and survival. In fact, IRS-2 is a key molecule in the control of beta cell mass and is directly phosphorylated by the insulin receptor after insulin binds the latter, leading to the recruitment and activation of additional signalling proteins. Ablation of the IRS-2 gene in mice results in a phenotype with characteristics of human type-2 diabetes - they progress toward diabetes as beta cell mass decreases and insulin secretion fails. Sodium Tungstate could be involved in the reversion of the diabetic phenotype observed by acting independently of the insulin signalling pathway. In the present work, we used IRS2 knockout mice and examined the effects of tunsgtate administration in order to check for its potential targets as well as its therapeutic potential.
Materials and methods: 10 weeks wild type and knockout IRS2 C57Bl/6 mice were divided into two groups, untreated and treated with a solution of 2mg/ml of sodium tungstate in distilled water. After 21 days metabolic studies such as glucose tolerance tests and morphometric analysis of pancreatic sections by immunofluorescence techniques were performed in order to identify the effects of a tungstate treatment.
Results: Our results illustrated that tungstate administered orally normalised blood glucose concentration in IRS2 knockout, despite the initial high glycaemic values (fasting initial values: 221±26 mg/dl compared to 139±23 mg/dl at day 21). This was accompanied by an improvement of glucose tolerance of IRS-2 $^{-/-}$ treated versus untreated group, assessed by an intraperitoneal glucose tolerance test performed both before and after treatment (figure). Morphometric analysis of pancreatic sections of these animals revealed as expected a reduced total islet and beta cell area in the untreated IRS-2 $^{-/-}$ mice (45295um^2±29239 and 38402um^2±25014 respectively) when compared to wild-type animals (145722um^2±78299 and 137357um^2±77630); however, treated knockout mice showed comparable values (140211um^2± 84245 and 121277um^2± 74254).
Conclusion: Our results indicate that sodium tungstate may have an anti-diabetic effect in IRS-2 knockout mice and could help us understand the molecular mechanisms underlying the regulation of glucose homeostasis and endocrine plasticity.

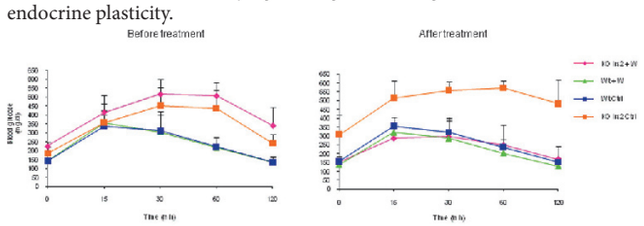

Figure. Glucose-tolerance tests after intraperitoneal loading with 2 g D-glucose per Kg were performed on 10-week-old animals of the indicated genotype

The effects of mildronate and metformin on energy metabolism pathways in experimental model of obesity

E. Liepins[1], E. Skapare[1,2], I. Konrade[2], M. Dambrova[1];
[1]Latvian Institute of Organic Synthesis, [2]Riga Stradins University, Riga, Latvia.

Background and aims: Mildronate is a cardioprotective drug, which mechanism of action is based on the regulation of carnitine concentration. In addition to its cardioprotective effects mildronate lowers blood glucose concentration and protects against diabetes complications in Goto-Kakizaki rats. The present study was carried out to investigate the metabolic effects of mildronate, metformin and a combination of the two in the experimental Zucker rat model of obesity and impaired glucose tolerance.
Materials and methods: Zucker rats were perorally (p.o.) treated daily with mildronate (200 mg/kg), metformin (300 mg/kg), and a combination of both drugs for 4 weeks. Weight gain and plasma metabolites reflecting glucose and lipid metabolism were measured by commercially available kits. The amounts of PPAR-alpha and PPAR-gamma as well as their target gene expression in heart and liver tissues were detected by Western blot and qRT-PCR analysis, respectively.
Results: Both tested drugs and the combination similarly decreased fed and fasted state blood glucose by 1-2 mmol/l. In addition, mildronate, metformin and the combination significantly decreased fed state plasma insulin concentration for 31%, 29% and 47%, respectively. Mildronate significantly stimulated the expression of PPAR-alpha in the heart and PPAR-gamma in the heart and liver. Also the increased expression of PPAR-alpha target genes in the heart, but not in liver tissues was observed. In contrast to monotherapy, treatment with the combination of mildronate and metformin significantly decreased the weight gain for 19%, while it did not affect food intake.
Conclusion: In conclusion, our results demonstrate that mildronate, an inhibitor of L-carnitine biosynthesis, enhances the anti-diabetic activity of metformin, mediates PPAR-alpha and PPAR-gamma activation and improves the adaptive responses against hyperglycemia- and hyperlipidemia-induced metabolic disturbances.

Analysis of spontaneous obese and diabetic mice induced by selective breeding with high fat diet

M. Nagao, F. Okajima, Y. Sato, S. Takemitsu, M. Sudo, T. Harada, Y. Nakajima, K. Tanimura, A. Asai, S. Oikawa;
Division of Endocrinology and Metabolism, Department of Medicine, Nippon Medical School, Tokyo, Japan.

Background and aims: Diabetes and obesity become more common due to modern lifestyle as environmental factor, and familial clustering as genetic factor is indicated in such a dysmetabolism. To elucidate the influence of present lifestyle to the next generation, we performed selective breeding of mice that had glucose dysmetabolism induced by high fat diet (HFD).
Materials and methods: Hybrid mice with male C57BL/6J, female C3H/HeJ and female AKR were used in this study. At first, male C57BL/6J mice were crossed with female C3H/HeJ mice, and mice were fed with 25% HFD for 10 weeks (5-15 weeks of age). Then casual blood glucose was checked and mice with higher blood glucose level were selected for breeding. At the 3rd generation, birth rate was reduced, so we crossed these male mice with female AKR mice, and fed these mice with 13.5% HFD for 10 weeks. From the 4th generation to date, oral glucose tolerance test (OGTT) was performed around 11 weeks old, and mice with higher blood glucose levels at 2 hours (2hr BG) were selected and bred as high glucose colony, H-strain. In the present protocol, mice were fed with 13.5% HFD from 5 to 10 weeks old to keep the normal birth rate. Despite HFD feeding, some of mice showed normal GTT pattern. These mice were also selected and bred as control (normal glucose colony; C-strain). Messenger RNA expression of several genes in liver, skeletal muscle, and fat tissues, which influence glucose metabolism and body weight, was evaluated by real time quantitative PCR at 5 weeks old before HFD feeding.
Results: Now we have maintained the 12th generation of H-strain and the11th of C-strain. At 10 weeks old (after HFD feeding), the frequency of IGT and DM (2hr BG level is 140-199 mg/dl and over 200 mg/dl, respectively) was significantly higher in H10 (96.4% in male and 45.0% in female) than C9 (9.1% and 0%, respectively) by chi-square test. Body weight gain after HFD feeding was accelerated in H-strain compared to C-strain, and increased to 32.3±3.1 vs 29.2±2.4 g (male, P=0.0003) and 24.0±1.9 vs 20.7±1.4 g (female, P<0.0001), respectively. There was no difference in food intake between the two groups. At 5 weeks old (before HFD feeding), 2hr BG level of OGTT was 161±42.6 vs 105±25.3 mg/dl (H vs C-strain of male, P=0.042) and 112±34.1 vs 67±12.2 mg/dl(H vs C strain of female, P=0.046), therefore H-strain already had abnormal glucose metabolism before fat load. Real time PCR analysis of 5 weeks old male mice showed that UCP-2 expression of liver and muscle was significantly elevated, and UCP-1 / -3 expressions of BAT were significantly decreased in H-strain compared to C-strain.
Conclusion: Abnormal glucose metabolism and obesity induced by HFD were accelerated by selective breeding, thus the susceptibility to HFD was transmitted to next generation. It is concluded that the new strain of obese and diabetic mice was established. Additionally, further analysis of these mice could reveal the genetic factors that regulate sensitivity to HFD.

***In vivo* efficient gene transfer to murine white adipose tissue using adeno-associated viral vectors**

V. Jimenez[1,2], S. Muñoz[1,2], E. Ayuso[1,2], X. Leon[1,2], M. Molas[1,2], M. Moya[1,2], I. Elias[1,2], T. Ferre[1,2], S. Franckhauser[1,2], F. Bosch[1,2];
[1]CBATEG and Department of Biochemistry and Molecular Biology, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, [2]CIBER of Diabetes and Associated Metabolic Disorders, Barcelona, Spain.

Background and aims: Obesity is a worldwide growing health problem and this alteration of the metabolic and endocrine functions of adipose tissue is frequently associated with insulin resistance and type 2 diabetes. In order to increase our knowledge about the molecular mechanisms that underlie obesity, the overexpression or knockdown/silencing of specific genes in adipose tissue may offer great potential. However efficient gene transfer postnatally into adipocytes in vivo has not been achieved. Therefore, this study was designed to test the ability of adeno-associated viral vectors (AAV) serotypes 1, 2, 4, 5, 6, 7, 8 and 9 to achieve broad, efficient and persistent gene transfer to murine white adipose tissue in vivo.
Materials and methods: AAV vectors coding GFP as a marker gene or the enzyme Hexokinase II (HKII) were generated by triple transfection in 293 cells and were purified by double cesium chloride gradient. AAV vectors were injected into the epididymal white adipose tissue of mice.
Results: To asses the in vivo transduction efficiency of the adipose tissue with adeno-associated viral vectors, AAV serotypes 1, 2, 4, 5, 6, 7, 8 and 9 encoding the marker protein GFP were injected into the epididymal white adipose tissue (eWAT) of mice. Two weeks after the injection, fat pads treated with AAV8 and AAV9 presented the highest GFP content that paralleled the highest numbers of transduced adipocytes indicating that these two serotypes were the most efficient transducing adipocytes in vivo. In addition, to examine whether in vivo AAV-transduced adipocytes may be a viable model to study adipose function, differentiation and metabolism, gene transfer of key metabolic genes such as HKII into eWAT was also evaluated. Two weeks after injection, isolated adipocytes from mice injected with AAV9 vectors coding HKII presented a 3-fold overexpression of HKII mRNA compared with adipocytes from AAV9 null-injected mice. In AAV9-HkII-transduced adipocytes, insulin produced a marked increased in the 2-[1-3H]deoxy-D-glucose uptake compared to AAV9 null-transduced adipocytes at low and maximal insulin concentrations in a dose dependent manner.
Conclusion: All together, these results show that AAV vectors may be very useful for genetic modification of adipose cells in vivo to analyze adipocyte function or to assay new gene therapy approaches targeting the adipose tissue.

Sitagliptin and metformin increase active GLP-1 by complementary mechanisms in treatment-naïve patients with type 2 diabetes

E.M. Migoya[1], J. Miller[1], W.-L. Luo[1], E. O'Neill[1], L. Morrow[1], M.J. Gutierrez[2], A. Stoch[1], J.A. Wagner[1];
[1]Merck Sharp & Dohme Corp, Rahway, [2]Comprehensive Phase I, Miramar, USA.

Background and aims: Sitagliptin (SITA) and metformin (MET) are oral antihyperglycemic agents with different, complimentary mechanisms-of-action. Because treatment of type 2 diabetes mellitus (T2DM) usually requires combination therapy we assessed the potential combination effects of SITA and MET on GLP-1 in patients with T2DM.
Materials and methods: This was a randomized, placebo (PBO)-controlled, double-blind, 4-period crossover study in 18 treatment-naïve patients with T2DM. In each 2-day period, subjects received either SITA 100 mg in AM on Days 1 and 2, MET 500 mg in AM and PM on Day 1 and 1000 mg in AM on Day 2, co-administration of SITA+MET on Days 1 and 2 or PBO on Days 1 and 2. On Day 2, at 2 hrs post-AM dose, patients ate a standard meal. Blood samples were collected pre- and at specified times post-meal.
Results: Compared with PBO, SITA, MET, and SITA+MET reduced 2-hr post-meal glucose by 31, 40, and 74 mg/dL, respectively. Compared with PBO, MET alone increased cumulative 4-hr post-meal weighted mean (WM) total GLP-1 levels by 1.5-times while SITA slightly decreased levels by ~10%, consistent with feedback inhibition of GLP-1 release by increased active GLP-1. SITA or MET alone each increased cumulative 4-hr post-meal active GLP-1 levels by 2.2- and 1.7-times, respectively, and in combination by 3.4-times. MET increased active GLP-1 in proportion to the increase in total GLP-1, suggesting that the increase in active was primarily due to the increase in total GLP-1. In contrast, SITA increased active, but not total GLP-1, consistent with stabilization of the active peptide. These data are similar to previously reported results in healthy non-diabetic subjects.
Conclusion: Co-administration of SITA and MET enhances reductions in glucose and increases in active GLP-1, and may provide a unique benefit to patients with T2DM as a result of these complementary mechanisms-of-action.

Treatment	Geometric LS Mean (95% CI)[†]	Ratio of Geometric LS Means (Active/Placebo)(95% CI)
4-hr WM Total GLP-1 (pM)		
SITA	4.98 (4.24, 5.84)	0.87 (0.78, 0.97)
MET	8.73 (7.44, 10.2)	1.52 (1.37, 1.70)
SITA+MET	6.95 (5.93, 8.15)	1.21 (1.09, 1.35)
PBO	5.74 (4.89, 6.73)	---
4-hr WM Active GLP-1 (pM)		
SITA	9.06 (7.82, 10.5)	2.16 (1.87, 2.49)
MET	6.98 (6.02, 8.08)	1.66 (1.44, 1.92)
SITA+MET	14.3 (12.3, 16.6)	3.41 (2.95, 3.93)

Sitagliptin compared with glimepiride provides similar efficacy with weight loss and less hypoglycaemia when added to metformin therapy in patients with type 2 diabetes mellitus

B.J. Goldstein, T. Seck, Y. Chen, L. Duran, A.O. Johnson-Levonas, K.D. Kaufman, D.E. Williams-Herman;
Merck Sharp & Dohme Corp, Rahway, USA.

Background and aims: Current guidelines recommend the addition of a second antihyperglycemic agent when glycemic control is not achieved with metformin monotherapy. Sulfonylureas are the most common antihyperglycemic agents used in combination with metformin among patients who do not achieve or maintain glycemic control on metformin alone. In previous studies, the DPP-4 inhibitor sitagliptin (SITA) significantly improved glycemic control and was well tolerated when added to ongoing metformin monotherapy. The current study compared the efficacy and safety of SITA with the commonly-used sulfonylurea glimepiride (GLIM).
Materials and methods: A randomized, double-blind study was conducted in patients with T2DM who had inadequate glycemic control (A1C of 6.5%-9.0%) while on a stable dose of metformin (≥1500 mg/day for ≥12 weeks). After a 2-week placebo run-in period, 1035 patients were randomized to the addition of SITA 100 mg/day (N=516) or GLIM 1 mg/day (uptitrated to a potential maximum 6 mg/day; N=519) to ongoing metformin monotherapy for 30 weeks. The primary analysis evaluated whether SITA was non-inferior to GLIM in reducing A1C from baseline at Week 30 using a predefined non-inferiority margin of 0.4%.
Results: From a mean baseline A1C of 7.49% across treatment groups, LS mean changes at Week 30 were -0.47% for the SITA group and -0.54% for the GLIM group (between-group difference = 0.07% [95% CI: -0.03, 0.16]). The upper limit of the 95% CI for the between-group difference in change from baseline in A1C (0.16%) was less than the non-inferiority margin of 0.4%, supporting a conclusion of non-inferiority for SITA versus GLIM. The percentages of patients with A1C <7.0% at Week 30 were 52.4% (SITA) and 59.6% (GLIM). LS mean changes from baseline in fasting plasma glucose were -14.6 mg/dL and -17.5 mg/dL for SITA and GLIM, respectively. The percentage of patients for whom at least one adverse event of hypoglycemia was reported was significantly ($p<0.001$) lower with SITA (7%) than with GLIM (22%), with 73 and 460 events, respectively, reported. Treatment with SITA led to mean weight loss (-0.8 kg; 95% CI: -1.1, -0.5) while treatment with GLIM led to mean weight gain (1.2 kg; 95% CI: 0.9, 1.5), with a significant ($p<0.001$) between-group difference of -2.0 kg (95% CI: -2.3, -1.6).
Conclusion: In this study, the addition of SITA compared with the addition of GLIM to ongoing metformin monotherapy in patients with T2DM provided similar A1C-lowering efficacy after 30 weeks. Sitagliptin was generally well tolerated, with a lower risk of hypoglycemia and with weight loss compared with weight gain with glimepiride.

Efficacy and safety of sitagliptin and the fixed-dose combination of sitagliptin and metformin versus pioglitazone in drug-naïve patients with type 2 diabetes

A. Pérez-Monteverde[1], T. Seck[2], L. Xu[2], G. Liu[2], M.A. Lee[2], C. McCrary Sisk[2], D.E. Williams-Herman[2], K.D. Kaufman[2], B.J. Goldstein[2];
[1]Centro Médico Docente la Trinidad, Caracas, Bolivarian Republic of Venezuela, [2]Merck Sharp & Dohme Corp, Rahway, USA.

Background and aims: Combination therapy has been recommended for patients with type 2 diabetes mellitus (T2DM) who have greater degrees of hyperglycemia. The DPP-4 inhibitor sitagliptin (SITA) and the fixed-dose combination of sitagliptin + metformin (SITA/MET) are recent additions to the treatment options for patients with T2DM. This study assessed the efficacy and safety of therapy with SITA monotherapy and compared the efficacy and safety of SITA/MET with pioglitazone (PIO) monotherapy in patients with T2DM and moderate to severe hyperglycemia.
Materials and methods: After a 2-wk single-blind placebo run-in period 492 eligible patients (18-78 yr of age, HbA_{1c} 7.5-12%, not on an antihyperglycemic agent) were randomized 1:1 to SITA 100 mg once daily (qd) or PIO 15 mg qd (up-titrated to 30 mg after 6 wk). After the initial 12-wk double-blind active treatment period (Phase A) with SITA or PIO monotherapy, patients entered a 28-wk double-blind active treatment period (Phase B). At the beginning of Phase B, patients receiving SITA during Phase A were switched to SITA/MET (up-titrated to 50/1000 mg twice daily over 4 wk) and patients receiving PIO 30 mg qd at the end of Phase A were up-titrated to PIO 45 mg qd at the beginning of Phase B. No inferential testing for between-group differences (SITA vs. PIO) in HbA_{1c} change from baseline was done at the end of Phase A, since maximum glycemic efficacy of PIO was likely not achieved at this time point.
Results: Mean baseline HbA_{1c} was 9.0%. At the end of Phase A, SITA and PIO resulted in significant LS mean changes from baseline in HbA_{1c} (-1.0% SITA, -0.9% PIO), fasting plasma glucose (FPG; -1.5 mmol/L SITA, -1.6 mmol/L PIO) and 2-h post-meal glucose (-2.9 mmol/L SITA, -2.8 mmol/L PIO). At the end of Phase B, the LS mean changes from baseline in HbA_{1c} were -1.8% and -1.4% for SITA/MET and PIO, respectively (between-group difference -0.4%; $p=0.002$). A significantly greater proportion of patients had HbA_{1c} <7% in the SITA/MET group vs. the PIO group (55.0% vs. 40.5%, respectively; $p=0.004$). Significantly larger LS mean reductions at the end of Phase B were

observed with SITA/MET vs. PIO for FPG (-2.6 mmol/L vs. -2.1 mmol/L; p=0.03) and 2-h post-meal glucose (-5.0 mmol/L vs. -3.8 mmol/L; p=0.001). Both SITA/MET and PIO were generally well tolerated. A slightly higher incidence of adverse events (AEs) of abdominal pain (3.2% vs. 0.9%; p=0.083), nausea (2.7% vs. 0.9%; p=0.140), and vomiting (0.9% vs. 0.0%; p=0.150), and a lower incidence of edema (0.9% vs. 6.1%; p=0.003) were observed with SITA/MET vs. PIO. The incidence of hypoglycemia was low and similar in both groups (2.3% and 2.2% with SITA/MET and PIO, respectively). At the end of Phase B, SITA/MET resulted in a LS mean decrease in body weight (-1.1 kg) compared with a LS mean increase (3.4 kg) with PIO (between-group difference -4.5 kg; p<0.001).

Conclusion: In drug-naïve patients, SITA and PIO led to clinically meaningful improvements in glycemic control. Combination therapy with SITA/MET produced a significantly greater improvement in glycemic control compared with PIO. SITA/MET resulted in a decrease in body weight compared with an increase in body weight with PIO. SITA/MET was associated with a significantly lower incidence of edema and a slightly higher incidence of gastrointestinal AEs compared with PIO.

Safety and efficacy of linagliptin as add-on therapy to a sulphonylurea in inadequately controlled type 2 diabetes

A.J. Lewin[1], L. Arvay[2], D. Liu[2], S. Patel[3], H.-J. Woerle[4];
[1]National Research Institute, Los Angeles, USA, [2]Boehringer Ingelheim, Ridgefield, USA, [3]Boehringer Ingelheim, Bracknell, United Kingdom, [4]Boehringer Ingelheim, Biberach, Germany.

Background and aims: Linagliptin is an oral dipeptidyl peptidase (DPP-4) inhibitor under development for the treatment of type 2 diabetes (T2D). This 18-week (wk) multi-centre, randomised, double-blind, placebo-controlled parallel group study investigated the efficacy, safety and tolerability of linagliptin administered with sulphonylurea (SU) background therapy in participants with T2D and insufficient glycaemic control.

Materials and methods: Before being randomised to linagliptin (5 mg qd) (n=161), or placebo (n=84), all participants had a 2-wk placebo run-in. Any oral anti-diabetic (OAD) agent other than SU was withdrawn at the beginning of a 4-wk washout period prior to run-in. The SU drug was administered in an unchanged dosage throughout the entire trial duration (including washout and placebo run-in periods). The primary endpoint for the trial was the change in HbA_{1c} from baseline (BL) after 18 wks of treatment evaluated with an analysis of covariance (ANCOVA) adjusted for treatment, prior OAD(s) and BL HbA_{1c}.

Results: Mean BL characteristics (HbA_{1c} 8.6% [SD, 0.8]; fasting plasma glucose (FPG) 179.6 [50.9] mg/dL; age 56.9 [9.9] yrs; BMI 28.3 [5.0] kg/m^2) were similar between the groups. At Wk 18, the adjusted mean change in HbA_{1c} from BL was -0.47%, showing superiority of linagliptin over placebo (p<0.0001). Statistically significant differences between linagliptin and placebo for HbA_{1c} were sustained at all post-BL visits (wks 6, 12 and 18, all p<0.0001). Participants with a BL HbA_{1c} of ≥7.0% were 6 times more likely to achieve a response of HbA_{1c} to ≤7.0% at 18 wks when treated with linagliptin (15.2%) than those receiving placebo (3.7%) (odds ratio (OR) 6.47, p=0.006). The odds of achieving a HbA_{1c} reduction of ≥0.5% at 18 wks was greater for participants treated with linagliptin than in participants treated with placebo (OR 5.12, p<0.0001). At 18 wks, the improvements in glycaemic control were reflected in the difference in adjusted mean change in FPG from BL of -6.4 mg/dL (p=0.24) in favour of linagliptin. The proportion of participants requiring rescue therapy was twice as great for placebo (15.9%) compared to linagliptin (7.6%). Overall, the frequency of reported adverse events (AEs) was similar for the groups (42.2% in the linagliptin group and 42.9% in the placebo group). Of these AEs, 13/161 (8.1%) and 8/84 (9.5%) in the linagliptin and placebo groups, respectively, were considered drug-related by the investigator. AEs of severe intensity were reported for 4 participants (2.5%) in the linagliptin group and none in the placebo group; all other AEs were of mild or moderate intensity. None of the severe AEs was considered as drug-related. Investigator-defined cases of hypoglycaemia occurred in 5.6% and 4.8% of participants in the linagliptin and placebo groups, respectively. No changes in body weight or waist circumference were recorded.

Conclusion: Linagliptin treatment in combination with SU was well tolerated and produced statistically significant and clinically relevant reductions in HbA_{1c}. The safety results were comparable between linagliptin and placebo and, importantly, the addition of linagliptin did not result in a significant increase in hypoglycaemia. Linagliptin may provide an alternative option to uptitrating SU in participants failing on therapy with SU alone or in combination.

Linagliptin, a novel DPP-4 inhibitor: No need for dose adjustment in patients with renal impairment

U. Graefe-Mody[1], C. Friedrich[1], A. Port[1], A. Ring[1], T. Heise[2], A. Halabi[3], H.-J. Woerle[1];
[1]Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, [2]Profil Institut fuer Stoffwechselforschung GmbH, Neuss, [3]CRS Clinical Research Services Kiel GmbH, Germany.

Background and aims: Linagliptin is a potent and highly selective DPP-4 inhibitor in late stage development for the treatment of type 2 diabetes (T2D). Elimination of linagliptin occurs primarily non-renally; this is unique among the currently available DPP-4 inhibitors, which either require dose adjustment or are not recommended in patients with a creatinine clearance (CrCl) of ≤50 mL/min. The purpose of this study was to evaluate the influence of various degrees of renal impairment (RI) on the pharmacokinetics (PK) of linagliptin.

Materials and methods: Linagliptin PK was investigated in subjects with different degrees of RI: mild (CrCl 51-80 mL/min; n=6), moderate (CrCl 31-50 mL/min; n=6), severe (CrCl ≤30 mL/min; n=6), end-stage renal disease (ESRD, n=6) and in healthy volunteers (HV, CrCl >80 mL/min, n=6). In addition, linagliptin PK was compared in 10 patients with T2D with severe RI and in 11 patients with normal renal function (RF). Subjects received 5 mg linagliptin qd as single dose (severe RI and ESRD groups) or for 7 days (HV, mild or moderate RI) or for 10 days (patients with T2D). Plasma and urine concentrations of linagliptin, inhibition of plasma DPP-4, and plasma protein binding were determined. The primary analysis was the comparison of linagliptin exposure in steady state (subjects with mild or moderate RI vs HV and T2D patients with severe RI vs normal RF) or after single-dose (subjects with severe RI/ESRD vs HV).

Results: Steady-state total linagliptin exposure ($AUC_{\tau,ss}$) and maximum concentrations ($C_{max,ss}$) were comparable between subjects with mild RI and the control group, and showed a modest increase of 71 and 42 % in patients with moderate or severe RI, respectively (see table). Under single dose conditions, all patients with RI showed a 30-60% increase in total exposure (AUC_{0-24}) relative to the control groups, regardless of their degree of RI. There was no consistent increase in terminal half-life with deterioration of RF. Accumulation half-lives ranged from 14-15 h in the control groups to 18 h in severe RI. Only a weak correlation was seen between CrCl and steady state exposure or accumulation factor which is further evidence that RI plays a subordinate role in the elimination of linagliptin. Steady state renal excretion of unchanged drug was <7% of the dose in all groups. RI did not alter the plasma protein binding or the correlation between PK and DPP-4 inhibition.

Conclusion: Decreases in renal function had only a minor effect on the elimination of linagliptin. Based on the large safety window of linagliptin, the observed changes in exposure (~40% in severe RI) do not require dose adjustment in patients with T2D and renal impairment when treated with linagliptin.

	Steady-state		Single-dose	
RI Groups	$C_{max,ss}$ [nM]	$AUC_{\tau,ss}$ [nM·h]	C_{max} [nM]	AUC_{0-24} [nM·h]
Mild RI*	0.98 (0.70-1.39)	1.08 (0.91-1.28)	1.26 (0.80-1.96)	1.29 (1.01-1.66)
Moderate RI*	1.46 (0.98-2.19)	1.71 (1.34-2.18)	1.57 (0.77-3.19)	1.56 (1.06-2.32)

Linagliptin monotherapy improves glycaemic control in type 2 diabetes patients for whom metformin therapy is inappropriate

A.H. Barnett[1], R. Harper[2], R. Toorawa[2], S. Patel[2], H.-J. Woerle[3];
[1]University of Birmingham and Heart of England NHS Foundation Trust, United Kingdom, [2]Boehringer Ingelheim, Bracknell, United Kingdom, [3]Boehringer Ingelheim, Biberach, Germany.

Background and aims: Dose-related adverse events, such as diarrhoea, nausea and abdominal bloating, and a potential risk for lactic acidosis in subjects with renal impairment, may limit metformin use in patients (pts) with type 2 diabetes (T2D). This multi-centre, 18-wk, randomised, double-blind, placebo (PBO)-controlled, parallel group study (followed by an ongoing 34-wk double-blind extension period in which PBO pts were switched to glimepiride) assessed the efficacy, safety and tolerability of the oral DPP-4 inhibitor linagliptin (LI) (5 mg qd) in pts with inadequately controlled T2D for whom metformin therapy is inappropriate due to intolerability or contraindication.
Materials and methods: Hyperglycaemic T2D pts who were treatment-naive (HbA_{1c} ≥7.0 to ≤10.0%, or HbA_{1c} ≥7.0 to ≤9.0% in Canada) or pre-treated with 1 oral anti-diabetes agent (OAD) (HbA_{1c} ≥6.5 to ≤9.0% after a 6-wk washout period) were randomised to LI (n=151) or PBO (n=76) followed a 2-wk PBO run-in (previously treated pts went without medication for 4 wks prior to this). The primary endpoint for the trial was the change in HbA_{1c} from baseline (BL) after 18 wks of treatment evaluated with an analysis of covariance (ANCOVA) adjusted for prior OAD(s), BL HbA_{1c} and reason for metformin ineligibility. This interim analysis was conducted after all pts had completed 18 wks of treatment.
Results: There were no differences between the LI and PBO groups for mean BL characteristics (overall HbA_{1c} 8.09% [SD, 0.93]; fasting plasma glucose (FPG), 10.12 [2.54] mmol/L; age, 56.5 [10.3] yrs; BMI, 29.5 [5.4] kg/m^2). Most of the pts (61.2%) were female. The majority of pts had either normal renal function (55.9%) or mild renal impairment (34.4%). Metformin was inappropriate due to intolerance from gastrointestinal adverse events (AEs) in 93% of the randomised pts, with the remainder of cases due to raised creatinine. After 18 wks of treatment, the adjusted mean difference between LI and PBO was -0.57% with 95% confidence interval (-0.86, -0.29) (p<0.0001) in favour of LI for change in HbA_{1c} (%). Statistically significant differences between LI and PBO for HbA_{1c} were seen by Wk 6 and were sustained through Wk 18. Among pts with BL HbA_{1c} ≥7.0%, 11.8% of pts in the PBO group and 23.5% of the pts in the LI group achieved HbA_{1c} <7.0% at Wk 18. At Wk 18, linagliptin was superior to placebo in reducing the mean FPG from BL (adjusted mean difference -1.14 mmol/L with 95% confidence interval (-31.1, -9.9); p=0.0002). The percentage of pts requiring rescue therapy was higher in the PBO group (17.8%) compared with the LI group (11.6%). The proportion of pts experiencing ≥1 AE classed as drug-related within the LI and PBO groups was 6.6% and 1.3%, respectively. Hypoglycaemia was rare, occurring in 2 pts (1.3%) in the LI group and none in the PBO group and there were no severe cases in either group. No difference in weight was seen between groups.
Conclusion: LI showed superiority, with clinically relevant reduction in HbA_{1c} from BL to Wk 18 compared to PBO. LI was well tolerated, with comparable safety results between LI and PBO. The incidence of hypoglycaemic events during treatment with LI was very low, with no episodes of severe hypoglycaemia, and there was no weight difference between groups. This study shows that LI would be a valuable treatment option for pts with T2D for whom metformin therapy was inappropriate.

Diabetes duration and its impact on the effect of dutogliptin, a novel DPP4 inhibitor, on HbA_{1c} and fasting plasma glucose in type 2 diabetes mellitus

N. Rosenberg[1], L. Xie[1], H. Schneier[1], A. Genovese[1], H.-P. Guler[2];
[1]Forest Research Institute, Inc., Jersey City, [2]Phenomix Corporation, San Diego, USA.

Background and aims: Type 2 diabetes mellitus (T2DM) is characterized by a progressive decline in glycemic control, and disease duration may impact patient therapeutic response to medication. Dutogliptin is a novel and potent dipeptidyl peptidase 4 (DPP4) inhibitor currently in Phase III development for the treatment of T2DM. This post-hoc analysis of a 12-week, multicenter, randomized, double-blind, placebo-controlled trial evaluated the effect of diabetes duration on glycemic response to dutogliptin treatment vs. placebo in patients whose T2DM was not optimally controlled with metformin and/or thiazolidinediones (TZD).
Materials and methods: Patients with HbA1c ≥7.3% currently receiving metformin (≥1500 mg/day or maximally tolerated dose for at least 4 weeks prior to study entry) and/or TZD (at any labeled dose) were stratified by diabetes duration at study entry (< and ≥5 years). Patients were randomized to receive oral doses of dutogliptin 200 mg, 400 mg or placebo once daily. Changes from baseline in HbA1c and fasting plasma glucose (FPG) were assessed after 12 weeks of treatment.
Results: Overall, absolute LS mean reductions from baseline in HbA1c were significantly greater in both the dutogliptin 200 mg (-0.64%) and 400 mg (-0.82%) arms compared to placebo (-0.30%, p<0.01) at week 12. Similarly, the LS mean change from baseline in fasting plasma glucose (FPG, mmol/L) was significantly reduced compared to placebo in the dutogliptin 200 mg (-0.88; p=0.003) and 400 mg (-1.00; p<0.001) groups. However, in patients with <5 years of diabetes duration, reductions in HbA1c and FPG were greater than in patients with ≥5 years of diabetes duration compared to placebo. Patients with diabetes duration <5 years experienced the greatest absolute decrease from baseline in HbA1c in both the dutogliptin 200 mg (-0.778%) and 400 mg (-0.991%) groups compared to placebo (p<0.05). Patients in the dutogliptin 400 mg group with diabetes duration ≥5 years also had statistically significant improvements in both HbA1c (-0.641%) and FPG (-0.976 mmol/L) compared to placebo (p<0.05).
Conclusion: These results demonstrate the positive effects of dutogliptin in early diabetes and support earlier treatment of T2DM with dutogliptin.

Efficacy of saxagliptin in relation to baseline HbA_{1c} in a pooled analysis of 3 add-on pivotal randomised phase 3 clinical trials

P. Maheux[1], M. Donovan[2], E. Allen[2], N. Berglind[2], H. Bouzamondo[3];
[1]AstraZeneca, Brussels, Belgium, [2]Bristol-Myers Squibb, Princeton, USA, [3]Bristol-Myers Squibb, Paris, France.

Background and aims: Saxagliptin (SAXA) is a potent, selective dipeptidyl peptidase-4 (DPP-4) inhibitor, approved in Europe for treatment of type 2 diabetes (T2D) in combination with metformin, a sulphonylurea, or a thiazolidinedione (TZD). In the phase 3 programme, SAXA improved control of the glucose triad (HbA_{1c}, PPG and FPG) via a physiological pathway, with weight neutrality and a low incidence of hypoglycaemia. This analysis examines 2 key relationships within the pooled efficacy database with SAXA 5 mg dose, between (1) HbA_{1c} reduction and baseline HbA_{1c} levels, and (2) the proportion of patients reaching HbA_{1c} target (<7.0%) without hypoglycaemia and baseline HbA_{1c} levels, particularly the subgroup of T2D patients slightly above HbA_{1c} target.
Materials and methods: T2D patients (>18y) recruited into the studies, with HbA_{1c} ≥7% and on stable doses of metformin (study CV181-014; NCT00121667), submaximal glibenclamide (CV181-040; NCT00313313), or TZD (CV181-013; NCT00295633). Following a placebo (PBO) run-in period, patients were randomised to SAXA (2.5 or 5 mg od - CV181-040 and CV181-013) or SAXA (2.5, 5 or 10 mg once daily - CV181-014) or (PBO) in addition to ongoing antihyperglycaemic agent. In CV181-040, blinded up-titration of glibenclamide was allowed for patients on PBO. The primary endpoint in all studies was change from baseline HbA_{1c} at week 24. The analysis was carried

out on all patients with a baseline HbA_{1c} value randomised to SAXA 5 mg (n=628) or PBO (n=630) in the 3 studies. Subgroups were defined by baseline HbA_{1c}: <7.5% (SAXA n=126, PBO n=134); ≥7.5–<8% (SAXA n=116, PBO n=135); ≥8–<8.5% (SAXA n=129, PBO n=113); ≥8.5–<9% (SAXA n=102, PBO n=100); ≥9% (SAXA n=155, PBO n=148). Hypoglycaemia was considered to be all symptomatic episodes including confirmed hypoglycaemia (fingerstick glucose <2.8 mmol/L + symptoms). Patients missing data at week 24 were counted as not achieving target HbA_{1c}.

Results: Treatment groups were well balanced for baseline characteristics. SAXA 5 mg od resulted in reduction from baseline to week 24 in mean PBO-corrected HbA_{1c} in all subgroups; greater reductions were seen with increasing HbA_{1c} at baseline (Fig). Percentage of patients reaching target HbA_{1c} (<7.0%) without hypoglycaemia with SAXA 5 mg od and PBO in each subgroup are also shown.

Conclusion: Add-on therapy with SAXA 5 mg od for 24 wks provided clinically relevant reductions in HbA_{1c} vs PBO in patients with inadequately controlled T2D. Pooled subgroup analysis showed that HbA_{1c} reductions were greatest in those with higher baseline HbA_{1c} values. The proportion of patients who achieved target HbA_{1c} without associated hypoglycaemic episodes was highest in those with lower baseline HbA_{1c}. Among patients who were close to target HbA_{1c} at baseline (eg <7.5%), >50% achieved target HbA_{1c} without associated hypoglycaemic episodes over 24 wks, reinforcing the potential role of SAXA as an early add-on therapeutic option.

Mean (95% CI) PBO-corrected change from baseline in HbA_{1c} to week 24 and percentage of patients who achieved target HbA_{1c} without hypoglycaemia for baseline HbA_{1c} subgroups in the SAXA 5 mg od treatment group

Efficacy of saxagliptin according to patient baseline characteristics: a pooled analysis of three add-on pivotal randomised phase 3 clinical trials

E. Allen[1], M. Donovan[1], N. Berglind[1], P. Maheux[2];
[1]Bristol-Myers Squibb, Princeton, USA, [2]AstraZeneca, Brussels, Belgium.

Background and aims: Saxagliptin (SAXA) is a potent, selective dipeptidyl peptidase-4 (DPP-4) inhibitor, approved in Europe for the treatment of type 2 diabetes (T2D) in combination with metformin, a sulphonylurea or a thiazolidinedione (TZD). In phase 3 trials, SAXA demonstrated comprehensive glycaemic control with improvements in all components of the glucose triad (HbA_{1c}, postprandial plasma glucose, fasting plasma glucose) and was associated with weight neutrality and a low incidence of hypoglycaemia. The present analysis, using pooled data from the pivotal phase 3 studies, was conducted to evaluate any potentially important relationships between patient characteristics at baseline and the efficacy of SAXA.

Materials and methods: Patients with T2D recruited into the studies were aged >18 years, HbA_{1c} ≥7%, and were on stable doses of metformin (study CV181-014; NCT00121667), submaximal glibenclamide (CV181-040; NCT00313313), or TZD (CV181-013; NCT00295633). Following a placebo run-in period, patients were randomised to SAXA (2.5 or 5 mg once daily - CV181-040 and CV181-013) or SAXA (2.5, 5 or 10 mg once daily - CV181-014) or placebo in addition to their ongoing antihyperglycaemic agent. In CV181-040, blinded up-titration of the glibenclamide dose was allowed for patients randomised to placebo. The primary endpoint in all studies was change from baseline HbA_{1c} at week 24. This analysis was conducted using placebo-corrected pooled data from all patients randomised to SAXA 5 mg/day in the 3 studies. The following subgroups were defined according to baseline characteristics: gender (male, female); body mass index (BMI; <30, ≥30); age (<65, ≥65 y); T2D duration (≤1.5, ≤3, >3-<5, ≥5, ≥10 y); creatinine clearance (≤80, >80 mL/min,), homeostasis model assessment 2 β-cell function (HOMA-2B; ≤ and >58.6; baseline study median). The efficacy of SAXA (mean change from baseline in HbA_{1c} vs placebo at week 24) was determined for each subgroup category.

Results: Overall, 630 patients were treated with SAXA 5 mg/day in the 3 studies. Baseline characteristics were well balanced across treatment groups within each study (data not shown). Adjusted mean decreases in HbA_{1c} with SAXA 5 mg/day, relative to placebo, were observed for each of the subgroups (figure). Numerically, these mean decreases ranged from -0.52 to -0.93 with relatively larger mean decreases in patients with longer duration of T2D, lower baseline creatinine clearance, and lower baseline HOMA-2B.

Conclusion: This analysis demonstrates that HbA_{1c} lowering from baseline was greater than placebo across diverse demographic and diabetes subgroups over a 24-week period. It supports the use of SAXA 5 mg once daily, as an add-on therapy, in a broad range of patient types.

Mean (95% CI) change from baseline in HbA1c at week 24 by patient characteristic subgroup

Addition of alogliptin vs uptitration of pioglitazone dose in type 2 diabetes mellitus patients on metformin plus pioglitazone therapy

E. Bosi[1], G. Ellis[2], P. Moneuse[3], C. Wilson[4], P. Fleck[4];
[1]Istituto Scientifico San Raffaele, Milano, Italy, [2]Helderberg Diabetes and Medical Centre, Cape Town, South Africa, [3]Takeda Global Research & Development Centre (Europe), London, United Kingdom, [4]Takeda Global Research & Development Center, Inc., Lake Forest, USA.

Background and aims: Maintaining target HbA1c levels in type 2 diabetes mellitus (T2DM) usually necessitates escalation of drug doses and use of combination therapies. In this study, the efficacy of adding alogliptin, an investigational dipeptidyl peptidase 4 inhibitor, was compared with that of increasing the pioglitazone dose in patients experiencing inadequate glycemic control on a regimen of metformin plus pioglitazone.

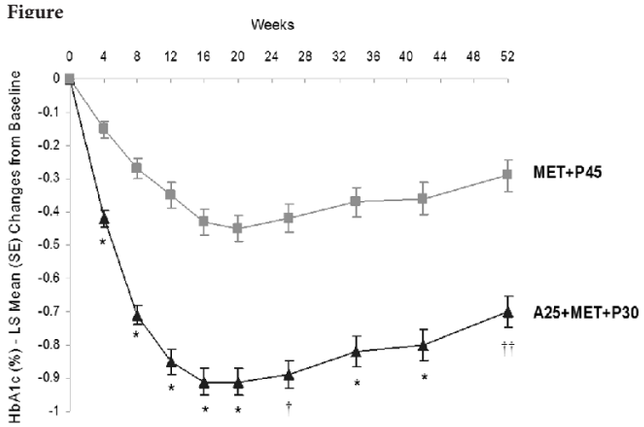
Materials and methods: The addition of alogliptin 25mg (A25) vs the titration of pioglitazone 30 (P30) to 45mg (P45) was evaluated in 803 randomized patients with inadequately controlled T2DM currently treated with metformin (MET; ≥1500mg or maximum tolerated dose) plus P30. The primary endpoint was glycosylated hemoglobin A1c (HbA1c) changes from Baseline (CFB) at Weeks 26 and 52, and the primary analysis involved sequential testing for non-inferiority at Weeks 26 and 52 and superiority at Week 52 only.

Results: The addition of alogliptin (A25+MET+P30) demonstrated superior glycemic control vs the titration of pioglitazone to 45mg (MET+P45), as measured by HbA1c least squares (LS) mean CFB at Week 26 (-0.89% vs -0.42%) and Week 52 (-0.70% vs -0.29%). A25+MET+P30 resulted in significantly (P<0.001) greater HbA1c reductions at all time points (Fig A), regardless of baseline HbA1c (<8%, ≥8%, <9%, ≥9%), and significantly (P<0.001) higher proportions of patients taking A25+MET+P30 vs MET+P45 achieved target HbA1c ≤7.0% (33.2% vs 21.3%) and ≤6.5% (8.7% vs 4.3%) at Week 52. A25+MET+P30 also was significantly more effective than MET+P45 in decreasing FPG (LS mean CFB at Week 52 were -14.6 vs -3.7 mg/dL; P<0.001).

Conclusion: The addition of A25 to an existing T2DM regimen of MET+P30 provided superior glycemic control and potentially improved β-cell function

when compared with MET+P45, with no clinically important differences in safety.

Figure



*P<0.001 vs MET+P45.
†Non-inferior to MET+P45.
††Non-inferior and superior to MET+P45.

Measures of β-cell function significantly (P<0.001) improved with A25+MET+P30 vs MET+P45, as shown by LS mean CFB to Week 52 in pro-insulin/insulin ratio (-0.048 vs -0.007) and HOMA β-cell function (15.02 vs 2.06), while effects on insulin sensitivity were similar (HOMA insulin resistance was 0.35 vs 0.54). Overall, 3.0% of patients reported hypoglycemia.

Efficacy and safety of alogliptin, a potent and highly selective DPP-4 inhibitor, in Japanese patients with type 2 diabetes mellitus

Y. Seino[1], K. Kaku[2];
[1]Kansai Electric Power Hospital, [2]Kawasaki Medical School, Okayama, Japan.

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor used for treatment of type 2 diabetes mellitus (T2DM). We investigated the efficacy and safety of ALO used alone and in combination with an α-glucosidase inhibitor (Voglibose : VOG), a thiazolidinedione (Pioglitazone : PIO), a sulfonylurea (Glimepiride : GLIM), or a biguanide (Metformin : MET) in Japanese patients with T2DM.

Materials and methods: Efficacy (decrease in HbA_{1C}, fasting plasma glucose, 2-hr postprandial glucose) and safety (adverse events) of ALO were evaluated after 12-week treatment in five randomized, placebo-controlled, double-blind studies in Japanese patients with T2DM. In addition, long-term efficacy and safety were evaluated in 40-week, open-label extension studies in subjects who had completed the corresponding 12-week study (total treatment duration: 52 weeks). HbA_{1C} was measured by HPLC method according to the Japanese Diabetes Society standard.

Results: A total of 1649 patients were randomized into one of five studies: a monotherapy study (N=480; mean baseline HbA_{1C} 7.53%), a combination study with VOG (N=230; mean baseline HbA_{1C} 7.62%), a combination study with PIO (N=339; mean baseline HbA_{1C} 7.50%), a combination study with GLIM (N=312; mean baseline HbA_{1C} 8.17%), or a combination study with MET (N=288; mean baseline HbA_{1C} 7.57%). At week 12, patients treated with ALO in monotherapy or in combination with VOG, PIO, GLIM, or MET showed statistically significant decreases in HbA_{1C} (Figure), fasting plasma glucose and 2-hr postprandial glucose from baseline compared to placebo. In all 12-week studies, incidences of adverse events, serious adverse events, drug-related adverse events, and hypoglyceamia were similar between ALO and placebo. In the open-label extension studies, ALO as monotherapy or in combination therapies provided substantial improvement in glyceamic control over 52 weeks without weight gain or increased incidence of hypoglyceamia.

Conclusion: Treatment with ALO, whether as monotherapy and in combination with VOG, PIO, GLIM, or MET, significantly improved glyceamic control and was well tolerated in Japanese patients with T2DM.

Efficacy and safety of liraglutide compared with glimepiride, both combined with metformin, in an Asian population

Y. Wenying[1], L. Chen[2], Q. Ji[3], A. Bhattacharyya[4], K.-W. Kim[5], K.-H. Yoon[6], H. Xu[7], A. Shinde[8], N. Tandon[9];
[1]China-Japan Friendship Hospital, Beijing, China, [2]Endocrinology, Wuhan Union Hospital, Hubei, China, [3]Xijing Hospital, Shaanxi, China, [4]Manipal Hospital, Bangalore, India, [5]Samung Medical Centre, Seoul, Republic of Korea, [6]Endocrinology and Metabolism, Seoul St Mary's Hospital, Seoul, Korea, Republic of, [7]Novo Nordisk Pharmaceuticals Ltd, Beijing, China, [8]Novo Nordisk Private Ltd, Bangalore, India, [9]All India Institute of Medical Sciences, New Delhi, India.

Background and aims: Liraglutide has been investigated for the treatment of type 2 diabetes in Caucasian, African-American and Hispanic populations as part of the LEAD programme. This study aimed to compare liraglutide with glimepiride, both added to metformin, in an Asian population from China, South Korea and India.
Materials and methods: In this 16-week, randomised, double-blind, active controlled trial, 929 patients were randomised to receive either liraglutide (0.6, 1.2 or 1.8 mg once daily; OD) or glimepiride (4 mg OD), both in combination with metformin (1 g twice daily; BD).
Results: Substantial reductions in HbA_{1c} were observed in all treatment groups (Table). Improvements in HbA_{1c} observed with liraglutide 1.2 and 1.8 mg were non-inferior to those reported for glimepiride. Both treatments let to greater improvements in HbA_{1c} in patients previously treated with oral antidiabetic drug (OAD) monotherapy. The proportion of patients reaching HbA_{1c} <7.0% was 36%, 45% and 47% for liraglutide 0.6, 1.2 and 1.8 mg, respectively, compared to 44% for glimepiride. Reductions in fasting plasma glucose were comparable across treatment groups. Liraglutide treatment led to weight loss of 1.8-2.4 kg, while glimepiride treatment resulted in 0.08kg weight gain. Greater reductions in systolic blood pressure (SBP) were observed for liraglutide than glimepiride. Liraglutide was associated with a ~10-fold lower incidence of minor hypoglycaemia than glimepiride. No major hypoglycaemia was reported for liraglutide. The composite endpoint 'HbA_{1c} <7.0%, no weight gain, no hypoglycaemia' was achieved by 29%, 39% and 41% of patients treated with liraglutide 0.6, 1.2 and 1.8 mg, respectively, compared with 17% of patients treated with glimepiride. The most common adverse effects associated with liraglutide were gastrointestinal disorders; however, these were transient in nature and led to very few withdrawals.
Conclusion: These results suggest that treatment with once-daily liraglutide leads to similar improvements in glycaemic control to glimepiride with additional benefits on body weight and SBP and a lower risk of hypoglycaemia. Patients treated with liraglutide are more likely to achieve HbA_{1c} target <7.0% without weight gain and hypoglycaemia. Both liraglutide and glimepiride appear to be efficacious when used early on in patients inadequately controlled with OAD monotherapy. These results from an Asian population are similar to those reported for Caucasian, African-American and Hispanic populations.

Monotherapy with GLP-1 receptor agonist, Lixisenatide, significantly improves glycaemic control in type 2 diabetic patients

J.E. Gerich[1], V.A. Fonseca[2], R. Alvarado-Ruiz[3], D. Raccah[4], I. Zieleniuk[5], G. Boka[5], P. Miossec[5];
[1]University of Rochester School of Medicine, Rochester, USA, [2]Tulane University Health Sciences Center, New Orleans, USA, [3]Clínica Cardioprevent, Durango, Mexico, [4]University Hospital Sainte Marguerite, Marseille, France, [5]sanofi-aventis, Antony, France.

Background and aims: This 12-week, randomised, double-blind, placebo-controlled, parallel-group, multicentre, Phase III study assessed the efficacy and safety of lixisenatide (AVE0010; a GLP-1 receptor agonist) as monotherapy in type 2 diabetic patients.
Materials and methods: A total of 361 patients with type 2 diabetes (mean age 53.7 yrs, mean diabetes duration 2.5 yrs) not currently receiving glucose-lowering therapy (HbA_{1c} 7-10%) were randomised to one of four once-daily treatment regimens: lixisenatide 2-step titration (10 µg for 1 week, 15 µg for 1 week then 20 µg; n=120), lixisenatide 1-step titration (10 µg for 2 weeks then 20 µg; n=119), placebo 2-step titration (n=61) or placebo 1-step titration (n=61). A 1-week, single-blind placebo run-in was followed by a 12-week, double-blind, placebo-controlled treatment period. The study was double-blind for active and placebo treatments, and not blinded for drug volume and titration regimens. The primary endpoint was change in HbA_{1c} from baseline to Week 12, analysed using ANCOVA with treatment group, screening strata for HbA_{1c} (<8.0, ≥8.0%) and BMI (<30, ≥30 kg/m²), and country as fixed effects, and baseline HbA_{1c} as covariate. A step-down testing procedure was applied. The two placebo groups were combined in all analyses.
Results: There were significant improvements in HbA_{1c} in both lixisenatide titration groups vs placebo (p<0.0001) (Table). Significantly more patients in the lixisenatide groups achieved HbA_{1c} ≤6.5% (31.9% 2-step, 25.4% 1-step) and <7.0% (52.2% 2-step, 46.5% 1-step) vs placebo (12.5% and 26.8%, respectively; p<0.01). There were also significant improvements in 2-h postprandial and fasting plasma glucose in the lixisenatide groups vs placebo (Table). Mean decreases in body weight were observed in all groups. There was only one (0.4%) serious treatment-emergent adverse event (TEAE) in a lixisenatide-treated patient (2-step group) compared with five (4.1%) in the placebo group. Nine patients discontinued due to a TEAE: five (4.2%) in the lixisenatide 2-step group, three (2.5%) in the lixisenatide 1-step group and one (0.8%) in the placebo group. The most common TEAEs were gastrointestinal: nausea was the most frequent (24.2% for lixisenatide 2-step, 20.2% for lixisenatide 1-step, 4.1% for placebo). Symptomatic hypoglycaemia occurred in three patients (2.5%) in the lixisenatide 2-step group, one (0.8%) in the lixisenatide 1-step group and two (1.6%) in the placebo group, with no cases of severe hypoglycaemia.
Conclusion: Lixisenatide monotherapy administered once daily significantly improved glycaemic control with a pronounced postprandial effect. Lixisenatide monotherapy was safe and well tolerated in patients with type 2 diabetes.

Table. Mean baseline and 12-week changes in glycaemic efficacy variables

			Lixisenatide	
		Placebo (n=121)	2-step titration (n=120)	1-step titration (n=118)
HbA_{1c} (%)	Baseline	8.07 ± 0.92	7.97 ± 0.91	8.06 ± 0.85
	Change from baseline	-0.19 ± 0.12	-0.73 ± 0.12	-0.85 ± 0.12

Exenatide significantly improved 24-hour average glucose compared to sitagliptin in patients with type 2 diabetes

S.K. Shenouda[1], J.H. Holcombe[2], C.R. Heilmann[3];
[1]Global Medical Communications, Eli Lilly and Company, Indianapolis, [2]Lilly USA, LLC, Indianapolis, [3]Eli Lilly and Company, Indianapolis, USA.

Background and aims: This study compared exenatide, a GLP-1 receptor agonist, and sitagliptin, a DPP-4 inhibitor, with respect to average 24-hour glucose (primary objective) and 2-hour postprandial glucose (PPG), insulin, glucagon, and active GLP-1 (aGLP-1) concentrations and caloric intake in patients with type 2 diabetes.
Materials and methods: This double-blind, double-dummy, randomized crossover study was conducted in 86 metformin or TZD-treated patients: 58% female; BMI 35±5 kg/m^2; A1C 8.3±1.0%. Patients received either exenatide [5µg twice a day (BID) for 1 week, then 10µg BID for 3 weeks] or sitagliptin (100mg one every morning) for 4 weeks. After 4 weeks, each group crossed to the other therapy for 4 weeks. At baseline and the end of each period, patients underwent 24-hour inpatient assessment with hourly or more frequent blood sampling for glucose, insulin, glucagon and aGLP-1. Based on gender and weight, each patient received the same individualized meals across the three 24-hour inpatient periods. 64 patients completed the study.
Results: The figure represents the 24-hour blood glucose profiles for exenatide and sitagliptin at baseline (BL) and endpoint (EP). Both treatments decreased average 24-hour glucose [exenatide 175±40 (BL) to 133±28 (EP) mg/dL; sitagliptin 175±39 (BL) to 146±33 (EP) mg/dL] and 2-hour PPG [exenatide 233±57 (BL) to 122±34 (EP) mg/dL; sitagliptin 233±57 (BL) to 186±51 (EP) mg/dL] from baseline (p<0.001), with the differences favoring exenatide (p<0.001). Both drugs decreased postprandial glucagon and improved the insulinogenic index from BL (p<0.05), but the improvements with exenatide were greater (p<0.001). Sitagliptin increased fasting and postprandial aGLP-1 from BL (p<0.001), while exenatide decreased postprandial aGLP-1 (p<0.05). There was no severe hypoglycaemia during the study and no dropouts due to an adverse event. Adverse events were mild to moderate in intensity and gastrointestinal in nature.
Conclusion: In conclusion, while exenatide and sitagliptin are both incretin-based therapies, exenatide demonstrated significantly better clinical effects compared to sitagliptin on average 24-hour glucose, PPG, insulinogenic index, and glucagon suppression.

Treatment satisfaction in patients with type 2 diabetes is significantly improved with liraglutide, the once-daily GLP-1 analogue versus sitagliptin, both combined with metformin

E. Montanya Mias[1], R. Cuddihy[2], R. Pratley[3], M. Hammer[4], A. Thomsen[4], M.J. Davies[5];
[1]IDIBELL-Hospital Universitari de Bellvitge, Barcelona, Spain, [2]International Diabetes Center, Minneapolis, USA, [3]University of Vermont, Burlington, United States, [4]Novo Nordisk, Søborg, Denmark, [5]Leicester University, United Kingdom.

Background and aims: Patient-reported outcomes (PRO) from clinical trials provide information on the impact of a disease on patients' health status, and may identify the extent to which treatments meet patients' needs and expectations. In a 26-week randomised, open-label study (n=665), the injectable once-daily human GLP-1 analogue liraglutide (1.2 or 1.8 mg), led to superior HbA_{1c} reduction vs orally-administered sitagliptin (100 mg OD), both added to metformin (MET; ≥1500 mg daily). Mean HbA_{1c} reduction (%) was 1.5, 1.2 and 0.9 for liraglutide 1.8 mg, 1.2 mg and sitagliptin, respectively (p<0.0001 for both liraglutide doses vs. sitagliptin). Liraglutide patients also lost significantly more weight (~3 kg vs. ~1 kg; p<0.0001). Here we report PRO results from a pre-defined subpopulation of this clinical trial.
Materials and methods: Treatment satisfaction (TS) was assessed using the Diabetes Treatment Satisfaction Questionnaire (DTSQ) at baseline and 26 weeks. Overall TS was calculated by adding satisfaction scores for 'current treatment', 'convenience', 'flexibility', 'understanding', 'recommend', and 'continue'. Higher scores indicate improved TS. For evaluation of perceived frequency of hyper- and hypoglycaemia, higher negative scores indicate improvement. TS scores were analysed by ANCOVA with treatment and country as fixed effects and baseline value as covariate.
Results: 505 subjects were included in the PRO analysis (liraglutide 1.2 mg, n=164; liraglutide 1.8 mg, n=171; sitagliptin, n=170). Baseline characteristics of the PRO subpopulation treatment groups were well balanced. Overall TS was similar between groups at baseline and improved in all groups after 26 weeks. Improvement in overall TS was significantly greater with liraglutide 1.8 mg (4.35) than sitagliptin (2.96) (difference=1.39; 95%CI 0.13; 2.64; p=0.03) (Figure). Patients also reported significantly greater improvement in TS with liraglutide 1.8 mg than sitagliptin on three sub-items: 'current treatment' (difference=0.35; p=0.01), 'recommend' (difference=0.41; p=0.003) and 'continue' (difference=0.44; p=0.01). Patients perceived themselves to be hyperglycaemic significantly less frequently with liraglutide 1.8 mg than sitagliptin (difference=-0.88; p<0.0001, and the same was found with the 1.2 mg dose (difference=-0.49; p=0.01). 'Convenience', 'flexibility', 'understanding' and 'perceived hypoglycaemia' were not statistically different between groups.
Conclusion: Injectable liraglutide leads to greater TS than oral sitagliptin, potentially by facilitating greater improvements in glycaemic control, weight loss and/or perception of superior treatment efficacy.

Exenatide added to a thiazolidinedione with or without metformin resulted in superior glycaemic control versus placebo after 26 weeks of treatment

J. Liutkus[1], J. Rosas Guzman[2], P. Norwood[3], L. Pop[4], J. Northrup[5], D. Cao[5], M. Trautmann[5];
[1]Medicine Professional Corporation, Cambridge, Canada, [2]Centro de Especialidades Médicas de Celaya, Celaya, Mexico, [3]Valley Research, Fresno, USA, [4]Diabetes Center-Emergency County Hospital, Baia Mare, Romania, [5]Eli Lilly and Company, Indianapolis, USA.

Background and aims: Exenatide, thiazolidinediones (TZDs), and metformin regulate blood glucose through unique and potentially complementary mechanisms. The objective of this 26-week study was to investigate the efficacy and safety of exenatide added to a TZD with or without metformin.
Materials and methods: A 26-week, multicountry, randomised, double-blind placebo-controlled study compared exenatide twice-daily vs. placebo, in 165 subjects with type 2 diabetes suboptimally controlled (HbA1c >7.0%) with a TZD or metformin + TZD (mean HbA1c 8.2% [SD 0.9], fasting glucose 9.1 [2.6] mmol/L, weight 93.9 [17.8] kg, diabetes duration 6.4 [4.3] years). After a 2-week, single-blind, placebo lead-in period, subjects were randomly assigned (2:1) to add exenatide or placebo to their current regimens. The primary endpoint was the change in HbA1c from baseline to endpoint (Week 26 or last-observation-carried-forward), using an analysis of covariance model with change in HbA1c from baseline to endpoint as the response variable and treatment, TZD stratum, country, and baseline HbA1c as explanatory variables.
Results: Approximately 95% (157/165) of the subjects were being treated with a TZD and metformin. At endpoint, exenatide reduced HbA1c significantly more than placebo (-0.84% [SE 0.20] vs. -0.10% [0.23], p<0.001; mean treatment difference, -0.74 [95% CI: -1.06% to -0.41%]). Reduction in mean fasting glucose was also significantly greater with exenatide (-0.65 mmol/L [SE 0.46] vs. +0.37 mmol/L [0.52], p=0.009). More subjects achieved HbA1c targets with exenatide (HbA1c ≤7.0%: 49% vs. 37%, p=NS; HbA1c ≤6.5%: 34% vs. 13%, p=0.004). Mean reductions in body weight were -1.4 [SE 0.6] kg with exenatide and -0.8 [0.7] kg with placebo; the between-treatment difference was not significant. Exenatide-treated subjects demonstrated a higher homeostasis model assessment of beta-cell function (HOMA-B index, geometric mean ratio of endpoint to baseline, 1.08 [0.12] vs. 0.84 [0.11]; p=0.009). Change in insulin sensitivity (HOMA-S index) was similar between treatment groups. The most commonly reported adverse events (exenatide vs. placebo) were nausea (12% vs. 2%) and vomiting (8% vs. 0%). Confirmed (blood glucose <3.0 mmol/L) minor hypoglycaemia was experienced by 4% and 2% of subjects treated with exenatide and placebo, respectively.
Conclusion: Adverse events were similar to those previously reported with exenatide with more gastrointestinal symptoms compared to placebo and a low risk of hypoglycaemia. Exenatide added to a TZD, with or without metformin, significantly improved HOMA-B and glycaemic control compared with placebo.

834

Liraglutide treatment provides greater weight loss with improved glycaemic control than sitagliptin, both combined with metformin

A. Garber[1], A. Thomsen[2], A. Falahati[2], R. Pratley[3];
[1]Baylor College of Medicine, Houston, USA, [2]Novo Nordisk, Søborg, Denmark, [3]University of Vermont College of Medicine, Burlington, USA.

Background and aims: Many standard diabetes treatments are associated with weight gain. Recently, incretin-based therapies have become available for the treatment of type 2 diabetes. In contrast to commonly used diabetes treatments, these incretin-based treatments promote weight loss (GLP-1 agonists) or are weight-neutral (DPP-4 inhibitors). How weight loss relates to improvements in HbA_{1c} remains unclear.
Materials and methods: In a 26-week randomised, open-label study liraglutide (1.2 or 1.8 mg), a once-daily human GLP-1 analogue, was compared with sitagliptin (100 mg), a once-daily DPP-4 inhibitor, both as add-on to metformin, in patients with type 2 diabetes (n=665; baseline HbA_{1c}: 8.5%). This study showed significantly greater reduction in HbA_{1c} (1.2% and 1.5% vs 0.9%, p<0.0001) and weight (2.9 kg and 3.4 kg vs 1.0 kg, p<0.0001) for liraglutide 1.2 mg and 1.8 mg, respectively, than sitagliptin. An ANCOVA analysis using the last observation carried forward (LOCF) intention to treat (ITT) population including effects of treatment, weight and their interaction with baseline HbA_{1c} as a covariate was carried out to investigate the impact of >3% weight reduction on the decrease in HbA_{1c} with liraglutide 1.2 mg (n=215), liraglutide 1.8 mg (n=214) and sitagliptin (n=215).
Results: This analysis demonstrated that treatment with liraglutide 1.2 mg and 1.8 mg led to significantly more patients losing >3% body weight (BW) than sitagliptin (51% [1.8 mg; p<0.0001] vs 21%). Also, weight reductions in the >3% BW change group were significantly greater for liraglutide 1.2 and 1.8 mg than sitagliptin (-5.75 kg and -6.30 kg [p=0.0342], respectively, vs -5.3 kg), while weight changes in the ≤3% BW change group were -0.02 kg, -0.17 kg and +0.38 kg, respectively for liraglutide 1.2 mg, liraglutide 1.8 mg, and sitagliptin. Patients treated with liraglutide who lost >3% weight had significantly greater reductions in HbA_{1c} compared to those who lost ≤3% weight (Figure). In contrast, similar reductions in HbA_{1c} were observed for patients treated with sitagliptin in both weight loss categories. Also, within each weight category, liraglutide treatment led to significantly greater improvements in HbA_{1c} compared with sitagliptin.
Conclusion: Liraglutide treatment resulted in significantly greater reductions in HbA_{1c} in those patients who experienced weight loss of >3%. Importantly, HbA_{1c} reductions were greater following liraglutide treatment in both weight loss categories compared with sitagliptin.

A meta-analysis of weight loss incurred by liraglutide in patients with type 2 diabetes with and without gastro-intestinal side-effects

D. Russell-Jones[1], G. Sesti[2], A. Garber[3], B. Zinman[4], K. Jensen[5], A. Falahati[5], S. Colagiuri[6];
[1]Diabetes and Endocrinology, Royal Surrey County Hospital, Guildford, United Kingdom, [2]University Magna Graecia of Catanzaro, Italy, [3]Baylor College of Medicine, Houston, USA, [4]Mt Sinai Hospital, University of Toronto, Canada, [5]Novo Nordisk, Søborg, Denmark, [6]University of Sydney, Australia.

Background and aims: The once-daily human GLP-1 analogue liraglutide is licensed for use as a blood-glucose lowering agent in type 2 diabetes mellitus (T2DM), but also improves cardiovascular risk factors associated with the condition, including systolic blood pressure, and weight. Gastro-intestinal (GI) symptoms such as nausea, vomiting or diarrhoea (NVD) are commonly reported class effects associated with GLP-1 agonists. Clinical studies of liraglutide suggest NVD side-effects are generally experienced early in therapy, and are usually transient and lead to very few withdrawals. Theoretically, NVD could

impact on eating habits and therefore caloric intake; our data explore whether these symptoms alone explain weight loss in patients taking liraglutide.
Materials and methods: This meta-analysis pools data from 6 phase 3 trials conducted in patients (n=2783) with T2DM treated with once-daily liraglutide or placebo for 26 weeks. Our aim was to explore the relationship between weight reduction and the occurrence of NVD. Changes in weight (kg) from baseline were analysed in patients with or without NVD in the different treatment arms using ANCOVA. The analysis included randomised treatment effect, previous anti-diabetes treatment effect, interaction between treatment and NVD, and correction for baseline body weight as covariates.
Results: Weight decrease from baseline to 26 weeks was significant for all groups, except those patients without NVD who were randomised to placebo, and numerical, but non-significant differences in weight loss were seen for the individual liraglutide doses (1.2 vs 1.8 mg) (Figure). The majority of patients taking liraglutide lost weight without NVD (75%). NVD symptoms were reported by 29%, 28% and 10% of patients treated with 1.8 mg liraglutide, 1.2 mg liraglutide and placebo, respectively. Symptoms were generally transient, whereas the weight-loss effect was sustained throughout the studies. No overall interaction was found between the effect of treatment and presence of NVD (p=0.26); however, patients with NVD lost more weight than those without: (p<0.0001 and p=0.0365) for liraglutide 1.8 mg and 1.2 mg, respectively.
Conclusion: Over 2/3 of patients included in the meta-analysis lost significant amounts of weight with liraglutide without experiencing nausea, vomiting or diarrhoea. Weight loss occurs regardless of NVD but is greater in those patients with NVD then in those without NVD.

Meta-analysis of the efficacy of GLP-1R agonists and DPP-4 inhibitors for treatment of type 2 diabetes mellitus

V.R. Aroda[1], R.R. Henry[2], J. Han[3], W. Huang[3], Y. Peters[3], T. Darsow[3], B.J. Hoogwerf[4];
[1]Med Star Clinical Research Center, Hyattsville, [2]University of California at San Diego, [3]Amylin Pharmaceuticals, Inc., San Diego, [4]Lilly USA, LLC, Indianapolis, USA.

Background and aims: The number of incretin-based therapies (glucagon-like peptide 1 receptor [GLP-1R] agonists and dipeptidyl peptidase 4 [DPP-4] inhibitors) and the amount of clinical data on their efficacy for treatment of type 2 diabetes mellitus (T2DM) are rapidly increasing. The aim of this meta-analysis was to summarize changes in HbA_{1c}, fasting glucose (FG), and weight for approved or late-stage GLP-1R agonists or DPP-4 inhibitors in studies published or presented at major scientific meetings before Dec 31, 2009.
Materials and methods: Medline, Embase, Biosis, and 2009 ADA and EASD abstract databases were searched for multiple terms including GLP-1, DPP-4, and individual drug names (exenatide [weekly-Ex QW; twice daily-Ex BID], liraglutide, alogliptin, saxagliptin, sitagliptin, vildagliptin). A database of search results was assessed by independent reviewers. Random effects meta-analysis models of the final studies for each therapy examined HbA_{1c}, FG, and weight data.
Results: Reviewers identified 219 unique clinical studies in patients with T2DM. Of these, 63 were randomized controlled clinical trials of 12 to 52 weeks duration with the primary endpoint of change from baseline in HbA_{1c}. The highest maintenance doses of GLP-1R agonists reduced HbA_{1c} to a greater extent than the highest maintenance doses of DPP-4 inhibitors. Ex QW and liraglutide treatment resulted in the greatest mean reductions in FG, whereas lesser mean reductions in FG were observed for Ex BID and DPP-4 inhibitors. Mean weight loss (>2.0 kg) was observed with GLP-1R agonists but not DPP-4 inhibitors. Limitations of the analysis include high inter-trial variation due to differences in amount of data, computation, blinding, comparators, and background therapy.

	GLP-1R Agonists		DPP-4 Inhibitors				
	Exenatide 2 mg QW	Exenatide 10 mcg BID	Liraglutide 1.8 mg QD	Alogliptin 25 mg QD	Saxagliptin 5 mg QD	Sitagliptin 100 mg QD	Vildagliptin 100 mg/d
Studies included	3	12	6	5	4	13	17
Subjects, N	323	2216	1345	902	581	2689	5210
Baseline HbA_{1c}, %	8.5	8.4	8.4	8.1	8.2	8.2	8.3
Δ HbA_{1c}, %	-1.7	-1.0	-1.2	-0.7	-0.7	-0.7	-0.9
[95% CI]	[-2.0, -1.4]	[-1.2, -0.9]	[-1.3, -1.1]	[-0.9, -0.5]	[-0.8, -0.5]	[-0.7, -0.6]	[-1.0, -0.8]
Δ FG, mmol/L[95% CI]	-2.0 [-2.4, -1.6]	-1.1 [-1.3, -0.9]	-1.7 [-2.0, -1.4]	-1.0 [-1.3, -0.7]	-0.9 [-1.3, -0.5]	-0.9 [-1.0, -0.7]	-1.1 [-1.2, -1.0]
Δ Weight, kg	-3.2	-2.1	-2.1	-0.3	-0.4	-0.1	0.0
[95% CI]	[-3.9, -2.4]	[-2.6, -1.7]	[-2.9, -1.2]	[-0.9, 0.3]	[-1.0, 0.1]	[-0.5, 0.3]	[-0.3, 0.3]

Number of studies and subjects are for the primary HbA_{1c} analysis. All Δs are from baseline.

Conclusion: All incretin therapies significantly reduced HbA_{1c} and FG from baseline. Treatment with GLP-1R agonists appeared to be associated with greater reductions in HbA_{1c}, FG, and body weight than were achieved with DPP-4 inhibitors. Further investigation of differences in efficacy between the GLP-1R agonists is warranted.

Risk of cardiovascular events in patients with type 2 diabetes treated with exenatide or other glucose-lowering therapies: a retrospective analysis of the LifeLink™ database

J.H. Best[1], B.J. Hoogwerf[2], E.M. Pelletier[3], D.B. Smith[3], M. Wenten[1], M.A. Hussein[4];
[1]Medical Research, Amylin Pharmaceuticals, San Diego, [2]Eli Lily and Co., Indianapolis, [3]IMS Health, Watertown, [4]IMS Health, Falls Church, USA.

Background and aims: Studies of agents that reduce hyperglycemia in patients with type 2 diabetes have shown differing effects on cardiovascular (CV) outcomes. Glucose-lowering therapies have been associated with increased risk, decreased risk, or neutral risk for CV events and/or mortality. The primary study objective was to assess the relative incidence rate of first CV events among patients with type 2 diabetes prescribed exenatide BID, a GLP-1 receptor agonist, compared to patients treated with glucose-lowering agent(s) other than exenatide (non-Ex).
Materials and methods: Analyses utilized the LifeLink™ database and included patients initiating a new prescription (Rx) for a glucose-lowering agent between June 1, 2005, and March 31, 2009, without Rx for the same agent in the prior 9 months. Patients were initially assigned to the exenatide or non-Ex group based on first new Rx and reassigned if exenatide was prescribed or discontinued. Patients were followed until one of the following occurred: CV event (acute myocardial infarction, stroke, or coronary revascularization procedure), insurance disenrollment, or study end. Patient outcomes adjusted for differences in clinical and demographic characteristics were compared using propensity-score-weighted discrete time survival analysis with time-varying exposure. An ITT analysis of hospitalization was also conducted.
Results: During the study, 39,275 and 381,218 patients were exposed to exenatide and non-Ex therapies, respectively. Age was similar_exenatide: 53 (±9) years; non-Ex: 53 (±11) years; 43.8% of exenatide patients were male and 51.5% of non-Ex patients were male. Exenatide patients were more likely than non-Ex patients to have hyperlipidemia (66.3% vs. 51.7%) and hypertension (65.4% vs. 56.3%). Exenatide-treated patients were 20% less likely to have a CV event than non-Ex patients (HR = 0.80; CI, 0.67-0.95). The exenatide group also had significantly lower rates of CV-related hospitalization (HR = 0.85; CI, 0.76-0.95; P = 0.005) and all-cause hospitalization (HR = 0.95; CI, 0.92-0.99; P = 0.004) than the non-Ex group.
Conclusion: In this analysis, exenatide treatment was associated with a lower risk of CV-related events than treatment with other classes of glucose-lowering therapies.

Taspoglutide, a once-weekly human GLP-1 analogue, is superior to Sitagliptin in improving glycaemic control and achieving weight loss in patients with type 2 diabetes: the T-emerge 4 Trial

J.-L. Chiasson[1], L.A. Leiter[2], A. Forti[3], R.M. Bergenstal[4], M. Woloschak[5], M. Boldrin[5], R. Balena[6];
[1]University of Montreal, Research Centre - CHUM, Montreal, Canada, [2]Keenan Research Centre in the Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, Canada, [3]Universidade Federal do Ceará, Fortaleza, Brazil, [4]International Diabetes Center, Minneapolis, USA, [5]Roche Pharmaceuticals, Nutley, USA, [6]F. Hoffman-La Roche, Basel, Switzerland.

Background and aims: This trial compared taspoglutide, a once-weekly human GLP-1 analog undergoing Phase 3 clinical trials, with sitagliptin and placebo in adult patients (pts) with type 2 diabetes (T2DM) inadequately controlled on metformin.
Materials and methods: In this double-blinded, 24-wk study, 666 adult pts with an A1c between 7%-10% were randomized (2:2:2:1) to subcutaneous taspoglutide 10 mg weekly (Taspo10), taspoglutide 20 mg weekly (Taspo20; titrated after 4 wks of 10 mg), sitagliptin 100 mg QD orally (SIT), or placebo (PL). The primary endpoint was change from baseline in A1c at week 24 using the intent-to-treat population. Superiority of Taspo10 and Taspo20 with PL and non-inferiority (NI) with SIT were tested. If NI with sitagliptin was shown (using 2 sided 95% CI difference and NI margin of ≤0.3), then superiority was tested under closed test procedure.
Results: Baseline characteristics were similar across the groups; average age was 56 yrs, A1c 8.0%, body mass index 32 kg/m^2, and duration of T2DM 6 yrs. Taspo10 and Taspo20, relative to SIT and PL, significantly reduced LS mean (SE) A1c (-1.23% [0.06], -1.30% [0.06], -0.89% [0.06], and -0.10% [0.08], respectively), body weight (Fig), and LS mean (SE) FPG (-2.16 [0.14], -2.33 [0.14], -1.35 [0.14], and -0.07 [0.20] mmol/l, respectively). Both Taspo10 and Taspo20 were superior to SIT for all 3 parameters. Target A1c of ≤7% was achieved by 68%, 72%, 55%, and 18% of pts receiving Taspo10, Taspo20, SIT, and PL, respectively. Gastrointestinal (GI) complaints were the most frequent adverse events and were reported in more pts receiving Taspo than SIT. GI events with Taspo were mostly mild and moderate in severity and transient in most pts; the withdrawal rate was 15%, 10%, 0.5%, and 1% of pts on Taspo10, Taspo20, SIT, and PL, respectively.
Conclusion: Once-weekly Taspo provided superior glycemic control and weight loss compared with SIT, while SIT had a lower incidence of GI adverse events. (NCT00754988)

Taspoglutide, a once-weekly human GLP-1 analog, as monotherapy significantly lowers HbA$_{1c}$ and body weight in patients with type 2 diabetes: results from the T-emerge 1 phase 3 trial

I. Raz[1], V.A. Fonseca[2], M.S. Kipnes[3], L. Durrwell[4], J. Hoekstra[5], M. Boldrin[6], R. Balena[4];
[1]Hadassah Ein Kerem Hospital, Jerusalem, Israel, [2]Tulane University, New Orleans, USA, [3]DGD Research/Cetero Research, San Antonio, USA, [4]F. Hoffmann-La Roche, Basel, Switzerland, [5]National Clinical Research, Richmond, USA, [6]Roche Pharmaceuticals, Nutley, USA.

Background and aims: Taspoglutide is a once-weekly human GLP-1 analog in Phase 3 clinical trials for T2D. This was a randomized, double-blind, placebo-controlled trial of taspoglutide monotherapy in drug-naïve patients.
Materials and methods: Adults (n=373) uncontrolled on diet and exercise with HbA1c between ≥6.5% and ≤10% were randomized 1:1:1 to subcutaneous taspoglutide 10 mg weekly (Taspo10), taspoglutide 20 mg weekly (Taspo20; after 4 weeks of Taspo10), or placebo (PL) for 24 weeks. The primary endpoint was the absolute change from baseline in HbA1c (%) after 24 weeks.
Results: Patient demographics were similar among the 3 groups; ~63% were women, mean age 54 yrs, body mass index 32 kg/m^2, mean HbA1c was 7.6% and duration of T2D ~2 yrs. Primary efficacy results at week 24 in the intent-to-treat population (ITT), using last observation carried forward (LOCF) are shown in the Table. Reductions from baseline in HbA1c and FPG were significantly greater with Taspo10 and Taspo20 than with PL. Target HbA1c of ≤6.5% was achieved by 59.8% (95% confidence interval [CI], 50.1-69.0), 66.1% (95 % CI, 57.2-74.3), and 17.4% (95% CI, 11.0-25.6) in the Taspo10, Taspo20, and PL groups, respectively. Reduction in body weight in the Taspo20 group was significantly greater than in PL (Table). The most frequently reported adverse events were nausea and vomiting, occurring at a greater incidence in the Taspo10 and Taspo20 groups than PL. Withdrawals due to gastrointestinal adverse events occurred in 5.2%, 7.8% and 0.8% of patients in the Taspo10, Taspo20, and PL groups, respectively.
Conclusion: Once-weekly taspoglutide as monotherapy in drug-naive patients with low baseline HbA1c, significantly improved glycemic control, reduced body weight, and was well tolerated. (NCT00744926)

Taspoglutide, once-weekly human GLP-1 analogue, compared to BID Exenatide improves glucose tolerance and insulin secretion in patients with type 2 diabetes: T-emerge 2 meal tolerance test

R. Ratner[1], J. Rosenstock[2], B. Balas[3], B. Charbonnel[4], G.B. Bolli[5], M. Boldrin[6], R. Balena[3];
[1]Medstar Research Institute, Hyattsville, USA, [2]Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, [3]F. Hoffmann-La Roche, Basel, Switzerland, [4]Universite de Nantes, France, [5]University of Perugia, Italy, [6]Roche Pharmaceuticals, Nutley, USA.

Background and aims: T-emerge 2 was a randomized, open-label, 24-week trial comparing subcutaneous taspoglutide 10 mg weekly (Taspo10), taspoglutide 20 mg weekly (Taspo20; titrated after 4 wks of Taspo10), with exenatide 10 mcg BID (Exe; after 4 weeks of Exe 5 mcg) in patients inadequately controlled on metformin, a thiazolidinedione, or both. T-emerge 2 demon-

strated that once-weekly Taspo provided better glycemic control than Exe. This report focuses on a subset of T-emerge 2 participants undergoing a standardized meal comparing Taspo to Exe which has been previously shown to lower postprandial glucose.
Materials and methods: Meal tolerance tests (MTT) were performed at baseline and at week 24 in a subset of Taspo 10, Taspo 20 and Exe patients (n=42, 39, and 67, respectively). Blood samples for glucose, insulin, glucagon, and C-peptide were obtained before and after (30, 60, 90, 120, and 180 min) ingestion of a standardized liquid meal.
Results: The 2-h postprandial, $mean_{0\text{-}3h}$ and $AUC_{0\text{-}3h}$ glucose during the MTT was reduced to a similar extent in all groups and the time profile of the postprandial glucose showed a similar pattern. Taspo10 and Taspo20 significantly increased insulin from baseline (both mean and $AUC_{0\text{-}3h}$) while the increase in insulin from baseline was not significant for Exe (Table). Although changes from baseline in C-peptide were not significant within any treatment group, the mean change from baseline (both $mean_{0\text{-}3h}$ and $AUC_{0\text{-}3h}$) was significantly increased in Taspo10 vs. Exe. Mean glucagon showed significant decreases in all groups (Table).
Conclusion: Taspoglutide and Exe improved glucose tolerance and reduced glucagon responses to a similar extent while taspoglutide alone significantly improved insulin secretion from baseline in patients with T2DM. (NCT00717457)

Disease progression modelling to quantify the effects of exenatide twice daily and once weekly formulations on HbA_{1c} in patients with type 2 diabetes
J.T. Mondick[1], P. Kothare[2], M.R. Gastonguay[1], B. Cirincione[3];
[1]Metrum Research Group, Tariffville, [2]Eli Lilly and Company, Indianapolis, [3]Amylin Pharmaceuticals, Inc., San Diego, USA.

Exenatide, a GLP-1 receptor agonist, is given twice daily (Ex BID) and indicated for patients with type 2 diabetes; and a once weekly (Ex QW) formulation is under development. The purpose of this analysis was to implement a population disease progression pharmacodynamic modeling approach to quantify the effects of demographic, clinical, and formulation characteristics on HbA_{1c} and to examine the effects of exenatide exposure on HbA_{1c} when transitioning patients (PT) from the Ex BID formulation to Ex QW. Clinical data was pooled from: (a) 3 Ex BID Phase 3 trials in PT treated with metformin (MET) and/or a sulphonylurea (SU); (b) 1 Ex QW Phase 2 trial in PT treated with MET and/or Diet and Exercise (DE); and (c) 1 comparative Phase 3 trial where PT, treated with MET, SU, thiazolidinedione (TZD), and/or DE, were initially randomised to Ex BID or Ex QW. Patients on Ex BID transitioned to Ex QW. The data set included HbA_{1c} measurements from 1272 exenatide and 496 placebo PT for up to 52 wk. A disease progression model was constructed using nonlinear mixed effects modeling for repeated measures data to describe the natural HbA_{1c} time course, placebo effects, exenatide effects, and the effects of patient and formulation characteristics on HbA_{1c}. The placebo and drug effects on HbA_{1c} were calculated from the estimated model parameters. The estimated baseline HbA_{1c} was 8.4% for the typical patient (100 kg, male, 55 y, no concomitant MET, TZD, or SU therapy). No significant differences in baseline HbA_{1c} were detected for gender or for concomitant administration with MET or SU. The baseline HbA_{1c} value was reduced by 0.44% (0.12, 0.69) for PT administered TZD. The placebo effect translated to a mean absolute reduction of 0.3% at 8 wk, and returned to baseline by approximately 30 wk. Mean (95% CI) steady-state HbA_{1c} levels were reduced by 0.8% (0.7, 0.9) and 1.2% (1.0, 1.5) for 5 μg and 10 μg Ex BID, respectively, and reduced by 1.4% (0.7, 2.8) for a 2 mg Ex QW dose. Patients who transitioned from 10 μg Ex BID to 2 mg Ex QW demonstrated an additional 0.2% response to Ex QW administration, demonstrating a clinical advantage of prolonged exenatide exposure.

DURATION-2: effect of switching to once-weekly exenatide from maximum daily doses of sitagliptin or pioglitazone
C.H. Wysham[1], R.M. Bergenstal[2], J. Malloy[3], B. Walsh[3], P. Yan[3], J. Malone[4], K. Taylor[3];
[1]Rockwood Clinic, Spokane, [2]International Diabetes Center, Minneapolis, [3]Amylin Pharmaceuticals, Inc., San Diego, [4]Eli Lilly and Company, Indianapolis, USA.

Background and aims: In the 26-week, double-blind, double-dummy assessment period of the DURATION-2 trial in patients with type 2 diabetes on metformin, treatment with the once-weekly GLP-1 receptor agonist exenatide (Ex QW) resulted in greater improvements in glycaemic control and weight compared to maximum approved doses of sitagliptin and pioglitazone. In the subsequent 26-week, open-label, uncontrolled assessment period, randomised oral medications were discontinued and all patients received Ex QW. The safety and efficacy of Ex QW treatment for 52 weeks, as well as the effects of switching from sitagliptin or pioglitazone to Ex QW, were evaluated.
Materials and methods: Of the 364 patients who continued into the open-label period and received at least 1 Ex QW dose (study entry baseline: HbA_{1c} 8.5±1.1%, fasting plasma glucose [FPG] 9.0±2.5 mmol/L, weight 88±20 kg), 319 patients (88%) completed 52 weeks. Results are reported for the 52-week evaluable population.
Results: Patients who received Ex QW throughout the trial demonstrated significant improvements from baseline in HbA_{1c}, FPG, and weight. At the end of the 52-week assessment period, 39% of patients treated with Ex QW for 52 weeks achieved HbA_{1c} ≤6.5% and 62% achieved the FPG target ≤7.0 mmol/L. Patients who switched from sitagliptin to Ex QW demonstrated significant incremental improvements in HbA_{1c}, FPG, and weight, and significantly more patients achieved HbA_{1c} ≤6.5% (week 26: 18% → week 52: 36%; P<0.001) and FPG ≤7 mmol/L (week 26: 38% → week 52: 58%; P<0.001). Patients who switched from pioglitazone maintained the improvements in HbA_{1c} and FPG observed during the initial 26 weeks, and a similar proportion of patients achieved HbA_{1c} ≤6.5% (40%) and FPG ≤7 mmol/L (59%) compared to patients treated with Ex QW for 52 weeks. However, switching from pioglitazone to Ex QW resulted in a significant weight reduction that reversed the weight gain associated with 26 weeks of pioglitazone treatment. Improvements in systolic blood pressure (SBP) with Ex QW and pioglitazone at week 26 were maintained at week 52 (-2.9±1.3 mmHg and -2.2±1.3 mmHg, respectively), while SBP was reduced by -2.7±1.1 mmHg (P<0.05) in patients who switched from sitagliptin to Ex QW (week 52: -2.9±1.2 mmHg). Ex QW was generally well tolerated and adverse events were predominantly mild or moderate in severity. Treatment-emergent nausea was the most frequent adverse event in this assessment period (ITT: Ex QW-only: 5%; sitagliptin → Ex QW: 11%; pioglitazone → Ex QW: 10%). No major hypoglycaemia was observed.
Conclusion: Switching to once-weekly exenatide from daily sitagliptin or pioglitazone resulted in improved or sustained glycaemic control with weight loss.

DURATION-5: Exenatide once weekly resulted in significantly greater improvement in glycaemic control than exenatide twice daily in patients with type 2 diabetes

J. Pullman[1], T.C. Blevins[2], J. Malloy[3], P. Yan[3], K. Taylor[3], C. Schulteis[3], M. Trautmann[4], L. Porter[3];
[1]Mercury St. Medical, Butte, [2]Texas Diabetes and Endocrinology Center, Austin, [3]Amylin Pharmaceuticals, Inc., San Diego, [4]Eli Lilly and Company, Indianapolis, USA.

Background and aims: Treatment with the GLP-1 receptor agonist exenatide results in improved glycaemic control and weight loss in patients with type 2 diabetes. This 24-week, randomised, open-label, comparator-controlled study compared treatment with exenatide once weekly (Ex QW; 2 mg) to exenatide twice daily (Ex BID; 10 mcg).
Materials and methods: The study was conducted in 252 intent-to-treat patients with type 2 diabetes (baseline [mean±SD]: HbA_{1c} 8.4±1.2%, fasting plasma glucose [FPG] 9.5±2.6 mmol/L, weight 96±20 kg). Patients were drug-naïve (18.7%) or treated with one (46.8%) or a combination (34.5%) of oral antidiabetic medications.
Results: Over 24 weeks of therapy, Ex QW resulted in significantly greater decreases from baseline (LS mean±SE) versus Ex BID in HbA_{1c} (-1.6±0.1% [Ex QW] versus -0.9±0.1% [Ex BID]; P<0.0001) and FPG (-1.9±0.3 mmol/L [Ex QW] versus -0.7±0.3 mmol/L [Ex BID]; adjusted P=0.0008). Improvements in HbA_{1c} were consistently observed across different background antidiabetic therapies. A significantly greater percentage of Ex QW patients (58.1%) achieved the HbA_{1c} target of <7% compared to Ex BID patients (30.1%; adjusted P<0.0001). A total of 41.1% of Ex QW patients achieved the HbA_{1c} target of ≤6.5% compared to 16.3% Ex BID patients (P<0.0001). Progressive reductions in mean body weight were observed in both treatment groups (change from baseline to Week 24 (LS mean±SE): -2.3±0.4 kg [Ex QW]; -1.4±0.4 kg [Ex BID]; not significant). A total of 71% of Ex QW patients and 51% of Ex BID patients had improvements in both body weight and HbA_{1c} after 24 weeks of therapy. Reductions in sitting systolic blood pressure from baseline to Week 24 were observed with Ex QW (LS mean [95% CI]: -2.9 [-5.2,-0.7] mm Hg) and Ex BID (-1.2 [-3.5, 1.2] mm Hg). Ex QW and Ex BID were well tolerated. Nausea, the most frequent adverse event, occurred less frequently with Ex QW (14%) than with Ex BID (35%) and was predominantly transient and mild or moderate in intensity. Injection-site reactions were infrequent and generally mild in intensity, but occurred more often with Ex QW compared to Ex BID. No major hypoglycaemia occurred. Minor hypoglycaemia was infrequent and occurred only in patients using a concomitant sulphonylurea. No change in mean calcitonin concentrations was observed during the study. Pancreatic-amylase and lipase concentrations were variable, both pre- and postbaseline, and changes in these enzymes were not predictive of gastrointestinal adverse events.
Conclusion: Continuous exenatide exposure via Ex QW therapy resulted in superior glycaemic control with fewer gastrointestinal adverse events compared to Ex BID in patients with type 2 diabetes. Both groups lost weight.

844

VRS-859, a monthly dosed glucagon-like peptide-1 (GLP-1) analogue, provides long-term glucose control in mouse models and lacks toxicity in mice and monkeys

J. Cleland[1], N. Geething[2], W. To[2], B. Spink[2], L. Lee[2], Y. Yao[2], J. Silverman[2];
[1]Versartis, Inc., Mountain View, [2]Amunix, Inc., Mountain View, USA.

Background and aims: VRS-859 is a novel, monthly dosed glucagon-like peptide-1 (GLP-1) analogue, being developed for treatment of type 2 diabetes (T2DM). VRS-859 is a fusion protein containing the GLP-1 analogue, exenatide, and a long hydrophilic tail of natural amino acids, XTEN, which increases the half-life. Mouse studies were performed to determine the relationship between the pharmacokinetics (PK) and pharmacodynamics (PD) of VRS-859. Toxicology studies were performed in mice and monkeys to ensure adequate safety for the proposed human dose. Single subcuntaneous doses of VRS-859 are being evaluated in a placebo controlled blinded study of patients with T2DM.
Materials and methods: Normal mice were treated with VRS-859 (1.2 to 120 nmol/kg) or exenatide and assessed for glycemic control and insulin secretion after intraperitoneal glucose tolerance test (IP GTT; AUC_{Glu} measured over 120 min and compared to placebo treatment) performed at intervals up to 72 hrs post-dose. VRS-859 (120 nmol/kg Q2D or 240 nmol/kg Q4D) or exenatide (infusion pump) was administered to diet induced obese (DIO) mice for 28 days. PK and toxicology of VRS-859 were assessed in mice dosed every other day with up to 50 mg/kg VRS-859 and cynomolgus monkeys dosed weekly with up to 35 mg/kg VRS-859 for 28 days. Clinical pathology, cardiovascular safety, and complete histology were performed in the toxicology studies. T2DM patients are being enrolled in a Phase 1 placebo controlled single ascending dose study of VRS-859. Patient evaluations include safety, tolerability, fasting plasma glucose, glycated albumin, HbA1c, oral glucose tolerance tests, insulin, and antibodies to VRS-859.
Results: Up to 48 hrs after IP VRS-859 dosing (120 nmol/kg), mice maintained a significant improvement in glucose tolerance (AUC_{Glu} = -53%), while exenatide only demonstrated significant improvement up to 1 hr post-dose. Insulin secretion after IP GTT was also increased up to 48 hrs after IP VRS-859 (120 nmol/kg) administration. There was a dose dependent glucose tolerance noted at 1 hr after dosing 1.2, 12 or 120 nmol/kg VRS-859 (AUC_{Glu} : -1, -54, and -66%, respectively). Correlating plasma levels of VRS-859 with the PD effects suggested that a human plasma level of 200 ng/mL VRS-859 may be sufficient to ensure glycemic control. After 28 days, DIO mice treated with VRS-859 had a significantly decreased body weight ($p < 0.01$) and fasting blood glucose ($p < 0.05$) compared to placebo, but exenatide infusion did not cause significant reduction in fasting blood glucose. The no observed adverse effect level of VRS-859 was 50 mg/kg in mice and 35 mg/kg in monkeys. Allometric scaling of the VRS-859 pharmacokinetics indicated a projected human terminal half-life of 139 hrs. Therefore, a 100 mg dose of VRS-859 may provide plasma levels sufficient to ensure glycemic control for one month in humans. Preliminary Phase 1 results including the pharmacokinetics and pharmacodynamics as well as safety and tolerability will also be presented.
Conclusion: VRS-859 provides sustained glycemic control and weight loss. A single subcutaneous dose of VRS-859 may enable glycemic control in a T2DM patient for one month.

845

Treatment with LY2189265 (GLP-1 analogue) causes larger decreases in postprandial glucose excursion in Hispanics compared to Non-Hispanic Caucasians with uncontrolled type 2 diabetes: an EGO Study exploratory analysis

E.J. Bastyr[1,2], J. Noriega[1,2], F.T. Botros[1], J. Shu[3], L.C. Glass[1];
[1]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, [2]Indiana University School of Medicine, Indianapolis, [3]i3 Statprobe, Ann Arbor, USA.

Background and aims: The Hispanic population is severely affected by the increasing incidence of type 2 diabetes mellitus, but studies of the differential responses to drug therapy in this group have received little attention. The objective of this exploratory analysis of the EGO study is to examine differences in glycemic control between Hispanic (H) and Non-Hispanic (NH) Caucasian populations in response to treatment with the long-acting glucagon-like peptide-1 (GLP-1) analog LY2189265 (LY).
Materials and methods: Subjects were randomized to once-weekly subcutaneous injections of either placebo or 1 of 3 LY dose regimens: 1) 1.0 mg for 16 weeks; 2) 0.5 mg for 4 weeks then titrated to 1.0 mg for 12 weeks; or 3) 1.0 mg for 4 weeks then titrated to 2.0 mg for 12 weeks. The primary metabolic measure for comparison between the 2 ethnic groups was glycemic control, as measured by HbA1c change from baseline at 16 weeks. Secondary measures were change in 1) fasting blood glucose (FBG); 2) β-cell function (HOMA2%B); and 3) glucose excursion (AUC) response to a solid mixed meal test. Differences between groups were tested using a two-sample T-test and nominal significance level of 0.05 for comparisons.
Results: In all randomized subjects, the H group had a statistically significantly higher baseline HbA1c compared to the NH group (8.4±1.0%, n=88 vs. 8.1±0.9%, n=150, p=0.006). The 177 patients randomized to LY treatment (62 H and 115 NH) had similar baseline characteristics; however, baseline HbA1c was 8.5±1.0% in H (n=62) compared to 8.2±0.9% in NH (n=114), p=0.078, and baseline postprandial AUC glucose excursion was significantly higher in H compared to NH (12.2±3.9 [mmol/L]•hr, n=60 vs. 10.3±5.3 [mmol/L]•hr, n=112, p=0.007). In response to LY treatment, both groups achieved statistically significant reductions in FBG and HbA1c. The H population experienced a greater reduction in HbA1c compared to NH at endpoint (-1.5±1.0%, n=61 vs. -1.1±0.8%, n=111, p=0.020), but changes in FBG were not significantly different between groups (-2.3±2.8 mmol/L, n=55 H vs. -1.8±2.5 mmol/L, n=92 NH, p=0.253). Changes in HOMA2%B were not significantly different between groups, but there was a 5.6-fold greater decrease

in postprandial AUC glucose excursion in the H group compared to the NH group (-2.8±3.8, n=56 vs. -0.5±5.7, n=89, [mmol/L]•hr, p=0.003). The percentage of subjects with ≥1 treatment-emergent adverse event in response to treatment with LY was similar between groups (58.1%, n=36 in H vs. 60%, n=69 in NH, p=0.803).
Conclusion: In conclusion, in response to treatment with LY, reductions in HbA1c were significantly greater in H compared to NH. This greater decrease in HbA1c in the H population appears to be due to the greater reduction in postprandial glucose excursion in H. Further studies are warranted to prospectively evaluate differential effects of LY treatment in the Hispanic population with type 2 diabetes mellitus.

Normalising action of GLP-1 and Exendin-4 on bone metabolism in obese state

B. Nuche-Berenguer[1], I. Gutiérrez-Rojas[1], D. Lozano[2], P. Esbrit[2], M.L. Villanueva-Peñacarrillo[1];
[1]Metabolism, Nutrition & Hormones, [2]Bone & Mineral Metabolism, IIS-Fundación Jiménez Díaz, Madrid, Spain.

Background and aims: The bone anabolic action of GLP-1 and exendin-4 (Ex-4) in normal, insulin resistant and type 2 diabetic rats has been demonstrated, the effect of GLP-1 being suggested to take part, at least partially, through specific receptors, distinct in structure and/or function from the pancreatic GLP-1 receptor. Hypercholesterolemia seems to be related with low levels of bone mineral density. Here we have explored the possible *in vivo* effect of GLP-1 and Ex-4 on bone turnover and other markers, in a diet-induced obesity rat model (OB), compared to normal (N).
Materials and methods: OB was obtained in adult Wistar rats by chronic feeding during five weeks with a *cafeteria diet*, consisting in standard chow supplemented with cookies, liver paste, bacon, and whole milk containing sucrose (333 g/l) and 10 g/l of a mineral and vitamin complex (65% energy from lipids). The N group was fed with standard chow and water *ad libitum* (8% energy as fat). Although weight was not different between N and OB rats, the OB model showed higher plasma glucose (78±2 mg/dl, n=12), triglycerides (153±13 mg/dl, n=11) and cholesterol (92±4 mg/dl, n=12) than those in N (overall mean: 37±5% Δ N-rats, $p<0.02$); no significant differences with N were detected in plasma insulin or GLP-1 -by RIA-. OB rats were 3-days continuously treated -osmotic pump- with saline (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1 nmol/kg/h). In fed conditions, blood samples were taken before (basal) and by the end of the treatment for plasma measurements; then, rats were sacrificed and the femorae, tibiae and L1-L4 vertebrae were collected. In the tibia, after total RNA extraction, osteocalcin (OC), osteoprogeterin (OPG) and RANK ligand (RANKL) gene expression -by RT-PCR- was determined; femoral and lumbar spine bone mineral densities (BMD) were also measured (Lunar Piximus).
Results: In the OB group, GLP-1 lowered the higher than normal triglycerides value (-33±6% Δ OB-basal, $p<0.05$, n=6 rats), without modifying that of cholesterol; however, Ex-4 induced a reduction in both triglycerides (-44±5% Δ OB-basal, $p<0.01$, n=6) and cholesterol (-19±3% Δ OB-basal, $p<0.01$, n=5). While plasma glucose, creatinin and insulin were not apparently different in any group or condition, calcium in OB was slightly higher ($p<0.01$) than that in N, without differences in the phosphates values; GLP-1 induced a decrease in the two latter parameters (overall mean: -8±2% Δ OB-basal, $p<0.01$, n=6) while Ex-4 reduced only the phosphate levels (-17.1±3.2% Δ OB-basal, $p<0.01$, n=6). In OB rats (n=12), BMD in femur (0.144±0.03 g/cm^3) and lumbar spine (0.128±0.03 g/cm^3) was lower (overall mean: -19±3% Δ N, $p<0.001$) than those in N-control rats (n=6-12), and either GLP-1 or Ex-4 exerted a normalizing effect (overall mean: 94±1% N, $p<0.001$). In the tibia of OB rats, OC mRNA level was equal to that in N, and both GLP-1 and Ex-4 induced an increase (overall mean: 2.23±0.21 times OB-control, $p<0.05$). In OB rats, bone OPG/RANKL mRNA ratio was 0.39, a value below that in N (considered as unity), indicating a high resorptive activity in this model; treatment with either GLP-1 or Ex-4 increased this ratio to values close to normal (0.76 and 0.80, respectively).
Conclusion: These data suggest that both GLP-1 and Ex-4 not only could correct the high lipid levels present in obese state, but also to normalize its possible deleterious bone metabolism through their common anabolic action.

The GLP-1 analogue liraglutide activates brainstem and hypothalamic neurons involved in appetite regulation

K. Raun[1], N. Vrang[2], J. Jelsing[2], M. Tang-Christiansen[1], K. Dahl[1], L. Bjerre Knudsen[1];
[1]Novo Nordisk, Måløv, [2]Gubra, Frederiskberg, Denmark.

Background and aims: The glucagon-like peptide-1 (GLP-1) analogue liraglutide is emerging as an important drug for the treatment of diabetes.

However, in both rodents and humans liraglutide also reduces appetite and lowers body weight.
Materials and methods: To identify the possible brain sites mediating liraglutide induced anorexia, we examined the expression of the immediate early gene c-Fos in male Sprague-Dawley rats. Based on the onset of liraglutide-induced anorexia, rats were terminated by perfusion fixation 4 and 8 h following s.c. or i.p. administration of liraglutide (0.1 mg/kg). Brain sections were immunoreacted for c-Fos and immunoreactive (ir) nuclei were assessed qualitatively throughout the brain. Six areas were selected for quantitative assessment.
Results: In the forebrain liraglutide increased c-Fos-ir nuclei in the central nucleus of amygdala (32±11; liraglutide s.c. 115±12; liraglutide i.p. 140±10, p<0.05 vehicle vs liraglutide s.c., i.p.) and in the hypothalamic paraventricular nucleus (PVN; vehicle 42±5; liraglutide s.c. 43±8; liraglutide i.p. 144±23, p<0.05 vehicle vs liraglutide i.p.). Conversely, liraglutide reduced c-Fos-ir nuclei in the arcuate nucleus (vehicle 45±10; liraglutide s.c. 16±4; liraglutide i.p. 21±6, p<0.05 vehicle vs liraglutide s.c., i.p.). In the hindbrain, liraglutide increased c-Fos in the area postrema (AP; vehicle 49±8; liraglutide s.c. 188±20; liraglutide i.p. 276±27, p<0.05 vehicle vs liraglutide s.c., i.p.), nucleus of the solitary tract (NTS; vehicle 27±5; liraglutide s.c. 150±17; liraglutide i.p. 161±21, p<0.05 vehicle vs liraglutide i.p.) and lateral parabrachial nucleus (lPBN; vehicle 13±4; liraglutide s.c. 87±15; liraglutide i.p. 117±13, p<0.05 vehicle vs liraglutide i.p., s.c.). Immunofluorescence was used to characterise liraglutide activated neurons. In the AP, liraglutide induced c-Fos in tyrosine-hydroxylase (TH)-ir neurons (vehicle 0±0; liraglutide s.c. 12.4±1.7; liraglutide i.p. 27.5±4%, p<0.05 vehicle vs liraglutide s.c., i.p.), whereas neither GLP-1-ir nor TH-ir neurons were activated in the NTS. In the PVN, liraglutide induced c-Fos in corticotrophin-releasing hormone-ir (CRH) neurons (vehicle 2±1; liraglutide s.c. 16±5; liraglutide i.p. 79±7%, p<0.05 vehicle vs liraglutide s.c., i.p.).
Conclusion: The data demonstrate that liraglutide activates the functional continuum involved in appetite regulation extending from the AP/NTS complex via the lPBN and amygdala to the PVN.

Extended, 3-year, exenatide therapy shows sustainable effects on beta cell disposition index in metformin treated patients with type 2 diabetes
M.C. Bunck[1], A. Corner[2], B. Eliasson[3], R.J. Heine[1,4], R.M. Shaginian[5], M.-R. Taskinen[2], U. Smith[3], H. Yki-Järvinen[2], M. Diamant[1];
[1]Department of Endocrinology / Diabetes Center, VU university medical center, Amsterdam, Netherlands, [2]Department of Medicine, Helsinki University Medical Center, Finland, [3]Lundberg Laboratory for Diabetes Research, Sahlgrenska University Hospital, Goteborg, Sweden, [4]Eli Lilly and Company, Indianapolis, USA, [5]Eli Lilly and Company, Houten, Netherlands.

Background and aims: We have previously showed that exenatide improved beta-cell function after 1-year treatment, relative to insulin glargine, with a similar glucose lowering effect. However, this effect was not sustained after a 4-week off-drug period. Here we report the effects on beta-cell function, presented relative to whole body insulin sensitivity as the disposition index, after the 2-year extension study.
Materials and methods: Sixty-nine metformin-treated patients with type 2 diabetes (mean±SD: age 59±8 y; HbA1c 7.5±0.8%; BMI 31±4 kg/m2; body weight 91.5±13.1 kg) were randomised to exenatide (n=36; 5µg BID for 4 weeks, 10µg BID with treat to HbA1c target ≤7%, maximum dose 20µg TID thereafter) or insulin glargine (n=33; treat to fasting plasma glucose (FPG) target <5.6 mmol/L). Forty-seven patients entered the 2-year open-label extension study of which 36 completed (exenatide n=16; insulin glargine n=20). Insulin sensitivity (M) and beta-cell function was measured by a combined euglycaemic-hyperinsulinaemic and arginine-stimulated hyperglycaemic clamp at baseline, and after a 4-week off-drug period, following the total 3-year treatment period. 1st-phase glucose stimulated C-peptide secretion was adjusted for the insulin-stimulated whole body glucose uptake (M) and presented as the disposition index (DI; AIRgluc*M).
Results: Both therapies reduced HbA1C similarly: by -0.7±0.3%, and -0.5±0.2% to 6.6±0.2% and 6.9±0.2% for exenatide and insulin glargine, respectively, after 3-years of treatment (P=0.186). Exenatide significantly reduced body weight compared to insulin glargine (between group difference: -7.9±1.8 kg; P<0.001), whereas treat to fasting plasma glucose insulin glargine more effectively lowered FPG (between group difference: -1.8±0.4 mmol/L; P<0.001). After the 4-week off-drug period, exenatide increased M by 39% (p=0.006) while insulin glargine had no effect on M (p=0.647). Following the 4-week off-drug period the DI was, compared to pre-treatment, higher with exenatide, and reduced with insulin glargine (+1.43±0.78 and -0.99±0.65, respectively; P=0.028). These findings are in contrast to the results following the 1-year treatment period, after which the DI did not show a sustained effect after the 4-week washout with either exenatide or insulin glargine. 2nd-phase glucose-stimulated, and combined glucose and arginine-stimulated C-peptide secretion did not show any significant between-group differences.
Conclusion: Exenatide and insulin glargine sustained HbA1C over 3-year treatment, while exenatide significantly reduced, and insulin glargine increased body weight. 1st-phase insulin secretion was sustained following a 4-week off-drug period, after 3-year treatment with Ex. This improvement cannot only be explained by glucose lowering.

Molecular mechanism of DPP-IV inhibitor vildagliptin effect on pancreatic beta cell preservation in diabetic mice: evidence for anti-oxidative and ER stress mechanism
S. Hamamoto, Y. Kanda, M. Shimoda, K. Tawaramoto, M. Hashiramoto, K. Kaku;
Diabetes and Endocrine Division, Kawasaki Medical School, Kurashiki, Japan.

Background and aims: DPP-IV inhibitors are known to produce several biological actions including glucose-dependent insulin secretion, increase pancreatic beta cell mass by stimulating cell proliferation and inhibit apoptosis. The aim of this study is to assess the molecular mechanism for preventive effect of vildagliptin on beta cell damage in diabetic animal model.
Materials and methods: Eight week-old male KK-*A*^{y}/TaJcl mice received vildagliptin (VILDA) (50mg/kg once daily orally) or vehicle (control) for 4 weeks (n=5). Body weight (BW), food intake, fasted blood glucose (FBG), fasted insulin (FIRI), TG and NEFA were measured at 8, 10 and 12 weeks of age. Intraperitoneal insulin tolerance test (ipITT:1 IU/kg BW), oral glucose tolerance test (OGTT:1 g/kg BW) and glucose stimulated insulin secretion (GSIS) from isolated pancreatic islet was performed at 12 weeks. The beta cell mass and cell proliferation were assessed by histological analysis including PCNA immunostaining of the islet tissue. Gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection method and real time RT-PCR. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, and oxidative/endoplasmic reticulum (ER) stress were prepared, and real-time RT-PCR with Sybr Green was applied.
Results: BW, food intake, FBG, FIRI, HOMA-IR, TG, NEFA, and ipITT were not different between the control and VILDA-treated groups. On the other hand, VILDA ameliorated glucose tolerance analyzed by OGTT, and a significantly higher plasma insulin response to glucose challenge was observed in VILDA group compared with the control group. Furthermore, GSIS with 16.7mM glucose was more significantly facilitated in VILDA group than in the control (2.24±0.72 vs. 1.57±0.42 ng/ml/islet, $p < 0.05$). The pancreatic beta cell mass was greater in VILDA-treated mice than in the control mice (5.0±0.9 vs. 2.9±0.9mg, $p < 0.01$, n=5 for each). The mRNA levels of Nkx2.2, Pax6, ERK1 and CyclinD associated with cell differentiation/proliferation were significantly higher in VILDA-treated mice than in the control mice. CAD and caspase3 mRNA levels were significantly decreased by VILDA treatment. VILDA significantly down-regulated XBP-1 gene expression related with ER stress, and up-regulated GSHPx gene expression related with anti-oxidative stress. The PCNA-positive cell ratio in the islet was increased significantly by VILDA treatment. On the other hand, VILDA decreased the 4-HNE-positive cell ratio. Morphometric results for PCNA and 4HNE observed corresponded with the data obtained in gene expression analysis.
Conclusion: Vildagliptin preserves the pancreatic beta cell function and cell mass in diabetic KK-*A*^{y} mice. The present results suggest that the effect of vildagliptin is resulted not only from the direct action on the cell kinetics regulation but also from the suppression of oxidative and/or ER stress mechanism.

Restoration of insulin release with lixisenatide in patients with type 2 diabetes

R.H.A. Becker[1], P. Ruus[1], Y.-H. Liu[1], C. Kapitza[2];
[1]Sanofi-Aventis Deutschland GmbH, Frankfurt/Main, [2]Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany.

Background and aims: Glucagon-like peptide (GLP-1) receptor agonists improve post-meal blood glucose levels in subjects with type 2 diabetes by restoring insulin release. We assessed the pharmacokinetics and pharmacodynamics of lixisenatide, a new GLP-1 receptor agonist.
Materials and methods: A two-period, two-sequence, single-centre, single-dose, cross-over study was performed. Twenty subjects with type 2 diabetes (treated with metformin or diet and exercise alone) with mean HbA_{1c} of 6.8% (range = 6.2-8.0%) and mean BMI of 30 kg/m² (range = 26-35 kg/m²) received single s.c. doses of 20 µg lixisenatide once-daily (intended therapeutic dose) or placebo injection 2 h prior to an intravenous glucose challenge (IVG; 0.3 g/kg body weight over 30 s). Baseline blood glucose was lowered to 5.5 mmol/L by fasting or insulin infusion (4 subjects) 30 min before the IVG. First ($AUC_{0\text{-}10min}$) and second ($AUC_{10\text{-}120min}$) phase insulin secretion, plus C-peptide and glucagon release and glucose disposition rate (K*glu*) were assessed and lixisenatide exposure was measured over 12 h.
Results: The maximum lixisenatide plasma concentration (C_{max}) was 84 pg/mL (coefficient of variation [CV], 25%), with a mean time to maximum concentration of 2 h (range 1-4 h). Lixisenatide 20 µg s.c. enhanced first-phase insulin secretion to IVG by 2.8-fold relative to placebo (90% CI 2.5-3.1), and second-phase secretion by 1.6-fold (90% CI 1.4-1.7) (Figure); corresponding changes were seen in insulin (1st-phase: 6.6-fold; 90% CI 5.0-8.7 and 2nd-phase: 3.0-fold; 90% CI 2.7-3.3) and C-peptide concentrations and glucose disposition (accelerated by 1.8-fold; 90% CI 1.6-1.9). Lixisenatide had little effect on basal insulin and glucose levels and did not affect glucagon suppression. Mild-to-moderate gastrointestinal symptoms (e.g. nausea and vomiting) were reported by two subjects following lixisenatide administration and one following placebo.
Conclusion: Lixisenatide 20 µg s.c. restored insulin release and accelerated glucose disposition following an IVG in subjects with type 2 diabetes, confirming this action as the basis of its control of postprandial blood glucose levels.

Liraglutide improves two indicators of beta cell function - HOMA-B and proinsulin:insulin ratio - in a meta-analysis of 6 clinical trials

D.R. Matthews[1], T. Vilsbøll[2], J.-P. Courrèges[3], M. Zychma[4], A. Falahati[5], B.W. Bode[6];
[1]Oxford Centre for Diabetes, Endocrinology & Metabolism, The Churchill Hospital, Oxford, United Kingdom, [2]Diabetes Research Division, Copenhagen, Denmark, [3]Diabetology and Vascular Disease Unit, General Hospital, Narbonne, France, [4]Novo Nordisk Pharma Sp.z.o.o., Warszawa, Poland, [5]Novo Nordisk, Søborg, Denmark, [6]Atlanta Diabetes Associates, Atlanta, USA.

Background and aims: The once-daily human GLP-1 analogue liraglutide reduced HbA_{1c} by 1.0-1.5% during the phase 3 development programme. A meta-analysis of 6 large phase 3 trials was conducted to investigate if HbA_{1c} reductions were associated with improvement in HOMA-B, a surrogate marker of beta-cell function based on fasting insulin and glucose levels, and proinsulin-to-insulin ratio. Failing beta-cells secrete an abnormally high amount of proinsulin relative to insulin, reflecting incomplete or defective proinsulin processing.
Materials and methods: The effect of 26 weeks of treatment with liraglutide (1.2 mg/1.8 mg OD), rosiglitazone (4 mg OD), glimepiride (4 mg/8 mg OD), exenatide (10 µg BID) or placebo on HOMA-B and proinsulin:insulin ratio was examined using an ANCOVA model adjusted for treatment, trial, prior treatment and baseline HOMA-B and proinsulin:insulin ratio.
Results: A significant increase from baseline in HOMA-B was observed with liraglutide and with glimepiride (both p<0.0001). The increase in HOMA-B was significantly greater with liraglutide 1.8 mg vs. exenatide, rosiglitazone and placebo (Table). Significant decreases from baseline in proinsulin:insulin ratio were observed with liraglutide (p<0.0001) and exenatide (p<0.001). Decreases in proinsulin:insulin ratio were significantly greater with liraglutide vs. rosiglitazone, glimepiride and placebo (Table). Liraglutide and glimepiride increased HOMA-B to a similar extent. However, these two agents can be differentiated on the basis of their effects on proinsulin:insulin ratio. Liraglutide stimulates insulin secretion in a glucose dependent manner while glimepiride produces a continuous, glucose-independent signal, potentially resulting in constant stress on beta-cells.
Conclusion: Liraglutide improves HOMA-B and proinsulin:insulin ratio, two indicators of beta-cell function. Since beta-cell function is a primary determinant of type 2 diabetes progression, it is possible that liraglutide may alter the decline in beta-cell function seen in patients with this disease. However, long-term studies will be necessary to confirm this effect.

Mean change in HOMA-B and P/IR from baseline to week 26

Treatment	Δ HOMA-B (%)	Δ P/IR
Liraglutide 1.8 mg OD (n=1363)	35.1	-0.08
Liraglutide 1.2 mg OD (n=896)	31.7	-0.08
Rosiglitazone 4 mg OD (n=231)	9.5**	-0.01*,††
Glimepiride 2-4 mg OD (n=490)	31.8	-0.02*,††
Exenatide 10 µg BID (n=231)	5.7*	-0.10
Placebo (n=524)	7.4*,†	0.03*,†

*p<0.0001 and **p<0.05 vs. liraglutide 1.8 mg; †p<0.0001 and ††p<0.001 vs. liraglutide 1.2 mg

Comparison between exenatide and glimepiride on metabolic control and on insulin resistance in type 2 diabetic patients with metformin therapy

S.A.T. Salvadeo[1], P. Maffioli[1], I. Ferrari[1], F. Querci[2], L. Ciccarelli[3], M. Piccinni[4], A. D'Angelo[1], A.F.G. Cicero[5], G. Derosa[1];
[1]Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S.Matteo, [2]Ospedale Pesenti Fenaroli, Bergamo, [3]Department of Internal Medicine, RSA Don Leone Porta, Milano, [4]Department of Clinical Medicine, Ospedale della Carità, Cremona, [5]Clinical Medicine and Applied Biotechnology Department, University of Bologna, Italy.

Background and aims: Our study aimed to compare the effect of Exenatide (Ex) vs Glimepiride (Gl) on glycemic control and on insulin resistance related-parameters in type 2 diabetic patients taking metformin.
Materials and methods: One hundred and thirty type 2 diabetic patients with uncontrolled type 2 diabetes [glycated hemoglobin (HbA_{1c} > 8 %)] were

randomised to Ex 5 μg b.i.d. or Gl 1.0 mg t.i.d. and titrated after 1 month to Ex 10 μg b.i.d. or Gl 2 mg t.i.d. They were resulted intolerant to metformin at maximum dosage (3000 mg/day) and were taking various different doses (1000-2000 mg/day). The treatment period had a 12 months duration. We evaluated body mass index (BMI), HbA_{1c}, fasting plasma glucose (FPG), post-prandial glucose (PPG), fasting plasma insulin (FPI), Homa index and collected plasma samples of adiponectin (ADN), and tumor necrosis factor-α (TNF-α) at baseline, and after 12 months.
Results: One hundred and eleven patients completed the study (57 in Ex and 54 in Gl group). BMI was significantly reduced by Ex, but not by Gl (from 28.4±1.3 to 26.6±0.9 Kg/m^2, p< 0.05, and from 28.5±1.4 to 28.2±1.3 Kg/m^2, ns vs baseline, p< 0.05 vs Ex, respectively). HbA_{1c} was decreased by 1.2±0.06 % (p< 0.01), and by 1.4±0.05 % (p< 0.01); FPG was reduced by 27±6 mg/dl (p< 0.01), and by 28±7 mg/dl (p< 0.01); PPG was decreased by 45±8 mg/dl (p< 0.01), and by 46±9 mg/dl (p< 0.01), in Ex and Gl group, respectively. FPI was decreased by 5.0±0.6 μU/ml (p< 0.05) in Ex group, and was increased by 1.2±0.09 μU/ml in Gl group (ns vs baseline, p< 0.05 vs Ex). Homa index was reduced by 2.7±0.8 (p< 0.05), and by 0.7±0.1 (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively. ADN was increased by 1.5±0.4 μg/ml (p< 0.05), and by 0.8±0.03 μg/ml (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively; TNF-α was reduced by 0.7±0.04 ng/ml (p< 0.05), and by 0.2±0.01 ng/ml (ns vs baseline, p< 0.05 vs Ex), in Ex and Gl group, respectively. There was a significant correlation between BMI value decrease and ADN increase (r= -0.57, p< 0.01), and TNF-α decrease (r= 0.61, p< 0.01).
Conclusion: Both Ex and Gl improved diabetes control when added to metformin, but only Ex improved insulin resistance related-parameters. The ADN increase, and TNF-α reduction seems to be related to weight loss.

853

Treatment of type 1 diabetic patients with residual beta cell function with the once-daily glucagon-like peptide-1 analogue liraglutide
U. Kielgast[1], J.J. Holst[2], S. Madsbad[1];
[1]Department of Endocrinology, Hvidovre University Hospital, Copenhagen, [2]Department of Biomedical Sciences, University of Copenhagen, the Panum Institute, Copenhagen, Denmark.

Background and aims: Information about the effects of treatment with GLP-1 receptor analogues in people with type 1 diabetes is sparse. Therefore, we investigated the effect of the once-daily GLP-1 analogue liraglutide on daily insulin dose, 24-hour glucose profile, glycaemic control, weight change and side effects in type 1 diabetic patients with residual beta cell function.
Materials and methods: Eight type 1 diabetic patients with HbA1c 6.6 ± 0.3 %, male/female ratio 7/1, age 27 ± 1.6 yr, BMI 24.3 ± 1.0 kg x m^{-2}, diabetes duration 3.7 ± 0.8 yr, and with plasma C-peptide concentration after 1 mg glucagon of 472 ± 107 pmol/l (range: 79-940) performed at a blood glucose of 15 mM, were treated for four weeks with liraglutide (0.6 mg for one week hereafter 1.2 mg daily if tolerated). All patients were treated with basal/bolus insulin therapy. Before initiation of liraglutide treatment, glycaemic control was optimized, and throughout the study patients were encouraged to maintain the best possible glycaemic control taking the risk of hypoglycaemia into consideration. Glycaemic control was evaluated during three days before start of liraglutide and the last three days of treatment through HbA1c, fructosamin and with patient blinded Guardian monitoring with logbook of meals and physical activity.
Results: Daily dose of insulin was significantly reduced from 0.53 ± 0.1 to 0.33 ± 0.1 U/kg/day, p< 0.001 during treatment with liraglutide despite no change in mean blood glucose, which was 6.1 ± 0.3 and 6.3 ± 0.4 mmol/l before and during the last three days of treatment, p=NS. Two patients completely discontinued their insulin treatment without loss of glycaemic control. The percentage of plasma glucose measurements below 3.9 mmol/l significantly decreased from 12.0 ± 4 to 5.1 ± 2, p=0.03. HbA1c decreased during treatment from 6.6 ± 0.3 to 6.2 ± 0.2, p=0.05 whereas no change was observed for fructosamin. All patients lost weight with a mean of -2.6 kg (range -1.5 to -3.6). Six patients had minor nausea, which was mostly transient, two patients experienced vomiting and four patients complained of abdominal pain and distension. Two patients tolerated only 0.9 mg liraglutide daily because of side effects.
Conclusion: Treatment with liraglutide in people with type 1 diabetes with residual beta cell function, may reduce the daily dose of insulin with improved or unaltered glycaemic control evaluated from fructosamin, HbA1c and mean glucose level evaluated during 3 days of Guardian monitoring. In type 1 diabetic patients with considerable residual insulin secretion, insulin treatment may be discontinued without impairment of glycaemic control. All patients lost weight during liraglutide treatment. Gastrointestinal side effects occurred frequently, but were mostly transient.

PS 77 GLP-1 analogues: safety and monitoring

Increased collagen production of human hepatic stellate cells (Ito Cells) induced by Exendin-4 (Exenatide) treatment
G. Firneisz[1], K. Baghy[2], K. Kiss[1], T. Varga[1], G. Nagy[1], I. Kovalszky[2], A. Somogyi[1];
[1]2nd Department of Medicine, [2]1st Institute of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary.

Background and aims: There are precautions about the potential for acute pancreatitis in patients taking Exenatide and these concerns were confirmed in experimental animal studies. Provided that a proportion of active glucagon-like peptide-1 (GLP-1) hormone also reaches the hepatic portal tract via the superior mesenteric vein after release form the small intestine we hypothesized that a hepatic effect should also exist even under physiologic conditions. We studied the potential effect of Exenatide on extracellular matrix (ECM) production of hepatic stellate cells (HSCs) that are thought to primarily produce the ECM proteins in the liver. These cells with fibrogenic potential were treated and co-treated with Exenatide and TGF- β1.
Materials and methods: Immortalized human HSC LX-2 cells were cultured at 37 °C atmosphere containing 5% CO2 with DMEM containing 10% FBS. Passages were made after 3-4 days using trypsin-EDTA. Cells were then cultured for 48 hours in FBS-free media that in the treated groups either contained Exenatide (cc=200 pg/mL) or TGF-β1 (cc=2ng/mL) or both (co- treatment). After mRNA isolation and RT-PCR Taq-Man real-time PCR assays were run in ABI 7000 System and human 18S rRNA was used for normalization. To evaluate the ECM production of HSCs ELISA assay was performed from the culture media using rabbit polyclonal primary antibodies against collagen-I and collagen-III. ECM protein synthesis was also assessed using Western Blots. Immun-cytochemistry (αSmooth Muscle Actin) was used to prove the activation of HSCs. All treatments were repeated 3 times and all runs were run in duplicates. Two-tailed T-test was used for statistical analysis.
Results: ECM protein production results measured by ELISA in the culture media are indicated in the following table (*= significantly increased compared to untreated controls, * * = significantly increased compared to TGF- β1 treatment). The collagen-III production of HSCs after Exendin-4 treatment was also assessed by Western blots that confirmed the ELISA results (collagen-I production was more preponderant after TGF-β1 treatment on Western Blot compared to ELISA) . The alterations of mRNA expression levels were reflecting the changes observed at protein level (upregulation) although to a less remarkable extent than the degree of change in collagen production.
Conclusion: These data confirm the existence of an incretin mediated entero-hepatic axis. Specifically we intended to uncover the distinct nature of the GLP-1 mimetic Exendin-4 and its effect on Hepatic Stellate Cells with fibrogenic potential. The surprising induction of human HSC collagen-III production by Exendin-4 treatment established a novel path of regulating the ECM production in the liver and urges further clinical trials not only to clarify the pancreatic effects but also with hepatic fibrosis and chronic liver disease endpoints.

Liraglutide protects against traumatic brain injury in a mouse model

B. Della Valle[1,2], J. Kurtzhals[2], M. Penkowa[1];
[1]Panum Institute, Copenhagen, [2]Centre for Medical Parasitology, Dept of Clinical Microbiology, Copenhagen University Hospital, Denmark.

Background and aims: Glucagon-like peptide-1 (GLP-1) analogues are emerging as an important drug class for the treatment of diabetes because they not only lower blood glucose but also body weight. Recently, several articles have pointed to a protective effect of GLP-1 or analogues on the brain and potential efficacy in animal models of stroke, Alzheimer's, Huntington's and Parkinson's disease. However, in some cases the compounds were dosed by the intracerebroventricular route. We here report the effect of liraglutide treatment during traumatic brain injury (TBI) in a mouse model. Liraglutide is a once-daily human GLP-1 analogue, the first to give 24 hours' coverage in patients. Since the effects in the brain are mediated at least in part by a protective mechanism, 24-hour coverage could be important.
Materials and methods: Liraglutide was injected s.c. (0.4 mg/kg) twice daily before and after mice received a cryo-induced cortical lesion until 7 days post-lesion. Control mice received a match volume of s.c. saline. Mice were processed for immunohistochemistry.
Results: When compared to the saline-treated controls, liraglutide-treated mice had less inflammation as reflected by a decrease in lectin + microglial activation. In liraglutide-treated mice 8-oxoguanine DNA adduct formation was reduced and largely specific to endothelial cells, whereas in saline-treated mice adducts were widespread through the lesion and present primarily in neurons, microglia and endothelial cells. Liraglutide improved tissue-healing response in TBI mice through concerted, lesion-directed astrogliosis, increased migration into the lesion and meninges formation, and improved blood-brain barrier reconstitution through reduced albumin leakage and increased perivascular astroglia.
Conclusion: Our data demonstrate that the GLP-1 analogue liraglutide promotes an anti-inflammatory, antioxidant state in a murine traumatic brain injury model and improves tissue healing and blood-brain barrier reconstitution. These findings warrant further investigation into the mechanisms of action and future studies will explore the potential of liraglutide in protecting against neuropathology.

The GLP-1 analogue liraglutide does not induce pancreatitis in mice, rats or monkeys

A.-M. Mølck, L. Madsen, N.C. Berg Nyborg, L. Bjerre Knudsen;
Novo Nordisk, Måløv, Denmark.

Background and aims: GLP-1 receptor agonists may be associated with an increased risk of pancreatitis in patients with type 2 diabetes. However the low overall incidence of pancreatitis and a 3-fold increase in pancreatitis rates in diabetes patients makes it difficult to assess if the association is true. Phase 3 studies with liraglutide in 4400 type 2 diabetes patients did not demonstrate a clear association between diabetes treatment and pancreatitis. A mechanism linking GLP-1 receptor activation to pancreatic inflammation has not been forthcoming.
Materials and methods: We report pancreas safety data in mice, rats and monkeys during the non-clinical development programme for liraglutide. Pancreases from mice, rats and cynomolgus monkeys were examined macro- and microscopically using state-of-the-art diagnostic criteria. Mice and rats were dosed for 2 years, monkeys 87 weeks (n=66-79/sex/group for mice, n=50 for rats, n=5 for monkeys; doses up to 3, 0.75, and 5 mg/kg/day, respectively in mice, rats and monkeys). Proliferation was measured using PCNA staining in rats after 26 weeks. The evaluation in monkeys included detection of signs of pancreatic intraepithelial neoplasia in the ductal epithelium.
Results: There were no macroscopic observations of pancreatitis in mice, rats or monkeys. After 2 years treatment, 8 out of 359 male (3 in the control group and 2, 1, 1, 1 in the different liraglutide groups) and 12 out of 354 female mice (0 in the control group and 3, 3, 3, 3 in the liraglutide groups) were diagnosed microscopically with pancreatitis based on histological criteria of inflammatory infiltrates with or without fibrosis and/or loss of exocrine tissue. Pancreatitis was not the cause of death in any of these animals and pancreatitis is seen spontaneously in mice. There were no cases of pancreatitis in 400 male and female rats, after 2 years dosing. Cell proliferation in the exocrine pancreas was not increased in rats dosed with liraglutide for 26 weeks. Neither pancreatitis nor pre-neoplastic proliferative lesions were found in monkeys dosed for 87 weeks, resulting in plasma liraglutide exposure 60-fold higher than that observed in humans at the maximal clinical dose.
Conclusion: In conclusion, liraglutide does not induce pancreatitis in rats or mice dosed for 2 years or in non-human primates dosed for 87 weeks.

The incidence of antibody formation and the levels of antibodies are lower with liraglutide than exenatide in a head-to-head comparison

J.B. Buse[1], E. Montanya[2], G. Sesti[3], M. Düring[4], H. Solberg[4], J. Rosenstock[5], M. Nauck[6], J.J. Holst[7];
[1]University of North Carolina School of Medicine, Chapel Hill, USA, [2]IDIBELL-Hospital Universitari Bellvitge, Barcelona, Spain, [3]University Magna Graecia, Catanzaro, Italy, [4]Novo Nordisk, Bagsvaerd, Denmark, [5]Dallas Diabetes and Endocrine Center, Dallas, USA, [6]Diabeteszentrum, Bad Lauterberg im Harz, Germany, [7]Panum Instituttet, Copenhagen, Denmark.

Background and aims: Antibody formation to therapeutic proteins can potentially affect pharmacokinetics, trigger adverse events, and/or diminish clinical response. Liraglutide (LIRA), a human GLP-1 analog, and exenatide (EXE), synthetic exendin-4 (a peptide originally identified in Gila monster saliva), are GLP-1 receptor agonists indicated for treatment of T2D with 97% and 53% homology to human GLP-1, respectively. Our objective was to detect and characterize antibodies to LIRA and EXE.
Materials and methods: LIRA and EXE antibodies were measured at wks 0, 12, 26, 40, 41, 78 and 79 in the LEAD-6 trial, which had a 26-wk head-to-head comparison of LIRA (1.8mg, once daily) and EXE (10µg, twice daily before meals), both + met and/or SU, followed by a 52-wk extension when EXE-treated patients switched to LIRA. Fasting samples collected prior to administration of trial products were screened for LIRA or EXE antibodies using a validated radioimmunoprecipitation assay. Plasma LIRA (30nM) reduced the sensitivity of the assay to detect low LIRA antibody levels from 25-50ng/mL to ~1500ng/mL. Thus, to avoid assay interference with plasma LIRA, LIRA antibody values presented were from end of trial after a ≥5-d (~7-9*$t_{1/2}$) wash-out. Because of its ~100-fold lower plasma concentration and short half-life (2.4h), plasma EXE levels were below the level of interference with the assay at the time samples were collected; therefore, EXE antibodies could be accurately measured during treatment.
Results: Of 467 patients, 389 (83%) entered the extension and 299 (64%) completed 78 wks. After 78 wks on LIRA, 4/154 (2.6%) patients off drug ≥5 d had low-titer LIRA antibodies (Fig, range: 1.9-5.3% Bound/Total [B/T]). HbA_{1c} changes in these 4 patients were 0.4, 0.8, -1.4 and -1.9% at 78 wks. After 26 wks on EXE, 113/185 (61%) extension patients had EXE antibodies (Fig, range: 2.4-60.2%B/T). EXE patients with high antibody titers (>20%B/T) had smaller HbA_{1c} reductions (-0.5%, N=47) than those with low titers (-1.0%, N=132). Patients with the highest EXE antibody titers (>50%B/T, N=6) had a -0.1% HbA_{1c} reduction. After switching from EXE to LIRA at wk 26, 90/181 (50%) and 25/143 (18%) patients had EXE antibodies at wks 40 and 78, respectively. Persistent EXE antibodies did not appear to affect glycemic efficacy with LIRA. Only 4/134 (3.0%) patients who switched from EXE to LIRA for 1 yr had LIRA antibodies.
Conclusion: LIRA resulted in a much lower frequency and magnitude of antibody formation than EXE. High-titer EXE antibodies affected glycemic response to EXE, but after switching to LIRA, persistent EXE antibodies did not compromise glycemic response to LIRA.

Antibodies to exenatide did not cross-react with human GLP-1 or glucagon or alter the efficacy or safety of exenatide

M. Fineman[1], K. Mace[2], M. Diamant[3], T. Darsow[1], B. Cirincione[1], T. Booker Porter[1], M. Trautmann[4];
[1]Amylin Pharmaceuticals, Inc., San Diego, USA, [2]Eli Lilly and Company, Indianapolis USA, [3]Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, [4]Eli Lilly and Company, Hamburg, Germany.

Background and aims: Consistent with the immunogenic properties of protein and peptide pharmaceuticals, patients may develop antibodies to exenatide with exenatide treatment. This analysis characterised the time course and cross-reactivity of antibodies produced against exenatide and effects on efficacy and safety.
Materials and methods: Antibody titers, and glycaemic and safety parameters were frequently sampled in 12 long-term controlled (2225 ITT patients, 12-52 wk duration) and 5 long-term uncontrolled (1538 ITT patients, up to 3 y) exenatide BID (Ex BID) trials and 4 long-term controlled (653 ITT patients, 26-30 wk) exenatide once weekly (Ex QW) trials.
Results: For Ex BID, mean antibody titers peaked between wks 6 and 16, and were reduced by 39.4% and 65.2% at wks 30 and 52, respectively. At wk 30, 37% of patients were positive for antibodies to exenatide. Of those, 32% exhibited low antibody titers (≤125) and a minority (5%) had higher antibody titers (≥625). At wk 52, 25% of patients were antibody positive (3% higher titer), and at 3 y, 17% were positive (1% higher titer). Lower titer antibodies had no effect on efficacy as evidence by comparable reductions in HbA_{1c} at endpoint in controlled trials (-1.0% for both antibody-negative and low-titer subjects). In the small number of patients with higher titers (5%), the impact on efficacy was variable, with the majority experiencing a glycaemic response consistent with antibody-negative patients. Similar trends were observed at 1 and 3 y. Other than injection-site reactions, no increased incidence of adverse events was observed with antibodies to exenatide. Cross-reactivity was examined in vitro for a subset of patients (106 antibody-positive patients), and treatment-emergent antibodies to exenatide did not cross-react with human GLP-1 or glucagon. Consistent with Ex BID, patients treated with Ex QW experienced titers that peaked between wks 6 and 16 and subsequently declined, with 56.8% of patients antibody positive (11.8% higher titer) at wk 26-30 and similar consequences on efficacy and safety.
Conclusion: Although patients may develop antibodies to exenatide, the titers peak early in treatment and decline thereafter, and are not predictive of safety and efficacy. Importantly, as antibodies to exenatide do not cross-react with the glucoregulatory hormones GLP-1 or glucagon and diminish over time, long-term clinical consequences are unlikely.

Relevance of sample collection method and specificity for the quantification of GLP-1-1 in two new ELISA assays for active and total GLP-1

A. Carlsson, M. Simonsson, R. Boman, M. Eberlein, P. Lindstedt;
Research and Development, Mercodia AB, Uppsala, Sweden.

Background and aims: The processing of proglucagon in the pancreas and small intestine give rise to a number of different peptides, including GLP-1. Intestinal derived GLP-1 (7-37) and (7-36)amide (often called active GLP-1) are rapidly degraded by the enzyme dipeptidyl peptidase-4 (DPP-IV) to GLP-1 (9-37) and (9-36)amide, resulting in very low amount of active GLP-1 in the circulation. The immunological determination of GLP-1 in a plasma sample is complicated by the potential cross reaction of the various proglucagon-derived peptides with antibodies raised against GLP-1 and the low amounts and rapid degradation of active GLP-1. In this study we investigated different sample collection methods including different inhibitors of the DPP-4 enzyme in two novel ELISA assays for GLP-1. The specificity for different GLP-1 isoforms were also determined.
Materials and methods: The crossreaction of GLP-1 (7-36)amide, (1-36)amide, (1-37), (7-37) and (9-36)amide were analyzed in two newly developed GLP-1 ELISAs for active and total GLP-1. Blood samples were collected from 9 healthy donors in 4 different EDTA tubes at the same occasion. Tube types 1 and 2 were precoated with lyophilized inhibitors (1 = DPP-IV inhibitors and 2 = A cocktail of protease, esterase and DPP-IV inhibitors). Tube 3 contained no DPP-IV inhibitor. A liquid DPP-IV inhibitor was added immediately after blood collection to tube 4. Plasma was prepared and the 4 sample types were then analyzed in the active and total GLP-1 ELISA assays.
Results: The GLP-1 active ELISA is specific for GLP-1 (7-36)amide (100% crossreaction) and do not detect GLP-1 (7-37), (1-37) or (9-36) (<0.4% cross-reaction). The crossreaction for GLP-1 (1-36)amide was 3.5%. The GLP-1 total ELISA is specific for GLP-1 (1-36)amide, (7-36)amide and (9-36)amide but do not detect non-amidated forms of GLP-1. When the 4 different sample types were analyzed in the GLP-1 active ELISA, tube 3 (EDTA only) showed a significantly lower content of GLP-1. There were no differences in GLP-1 content between the different inhibitors used in tubes 1, 2 and 4. (mean±SEM 2.1±0.3 pM for tube 3 vs. 4.5±0.7 pmol for tube 1, 4.6±0.7 pM for tube 2 and 4.5±0.8 pM for tube 4, $p < 0.002$, ANOVA). When samples were analyzed for total GLP-1, tube 2 contained somewhat higher amounts of total GLP-1 compared to tubes 1, 3 and 4 (mean±SEM 13.7±1.7 pM for tube 2 vs. 12.6±1.6 pmol for tube 1, 12.8±1.6 pM for tube 3 and 12.2±1.5 pM for tube 4, $p < 0.001$, ANOVA).
Conclusion: The ELISA for active GLP-1 is specific for GLP-1 (7-36)amide. The total GLP-1 ELISA was shown to be specific for all amidated isoforms of GLP-1. For detection of active GLP-1, it is important to include a DPP-IV inhibitor to prevent degradation. Both lyophilized and liquid DPP-IV inhibitors gave comparable results in preserving active GLP-1 in a plasma sample. DPP-IV inhibition does not seem to be essential for preservation of total amidated forms of GLP-1, but addition of protease and esterase inhibitors seem to induce some protection from degradation of total GLP-1 in a plasma sample.

Liraglutide: short-lived effect on gastric emptying - long-lasting effects on body-weight

L. Bjerre Knudsen[1], M. Tang-Christiansen[1], J. Jelsing[2], N. Vrang[2], K. Raun[1];
[1]Novo Nordisk, Maaloev, [2]Gubra, Frederiksberg, Denmark.

Background and aims: Previous studies with the novel once-daily GLP-1 analogue liraglutide and the GLP-1 mimetic exenatide have revealed profound insulinotrophic and anti-diabetic effects, but also long-term and lasting reductions in body-weight. Considering the marked inhibitory effects of GLP-1 on gastric emptying (GE), it is tempting to speculate that inhibition of GE could play a major role in the body-weight-lowering effects of liraglutide and exenatide. However, data for liraglutide indicate that the marked inhibition of GE diminishes over time, and thus cannot be the sole mechanism for body weight lowering.
Materials and methods: The present study was designed to test the effect of acute and chronic exposure of liraglutide and exenatide on GE, food intake and body weight. Based on a series of dose-finding studies we identified doses of exenatide (0.01 mg/kg) and liraglutide (0.2 mg/kg) with similar anorectic effects. GE was assessed using a standard acetaminophen release assay. Acetaminophen (40 mg/kg) was administered by gavage 30 min after an intravenous dose of exenatide and liraglutide. Rats were subsequently subcutaneously dosed bi-daily for 14 days after which GE was assessed again 30 min following the final sc injection of compounds.
Results: While both compounds exerted robust acute reductions on GE (area under the curve (µg/ml x min); vehicle 8520±290, liraglutide 1088±214, exenatide 1488±315; $p<0.0001$ vehicle vs liraglutide, exenatide) the effects on GE almost disappeared following 14 days dosing with liraglutide (vehicle 9362±469, liraglutide 8135±380; $p=0.022$). In contrast, exenatide treated rats still displayed a profound reduction in GE at the 14-day time-point (exenatide 591±137 µg/ml x min; $p<0.001$). Both compounds exerted similar chronic effects on body-weight (vehicle 350±4 g, liraglutide 318±5 g, exenatide 303±8; $p<0.0001$ vehicle vs liraglutide, exenatide).
Conclusion: The data suggest that the 'gastric inhibitory' GLP-1 receptors in rats are subject to desensitisation only during full 24 h exposure as obtained by liraglutide, whereas the GLP-1 receptors mediating the effects on body-weight are not. These data indicate that regulation of appetite signals in the brain, and not gastric emptying, is the main mechanism for liraglutide induced weight loss.

Safety and efficacy of using exenatide in combination with insulin in the Association of British Clinical Diabetologists (ABCD) nationwide exenatide audit

B. Jose[1], R.E.J. Ryder[1], K.Y. Thong[1], S. Thozhukat[2], W. Shafiq[2], ABCD Nationwide Exenatide Audit Contributors;
[1]Diabetes, City Hospital, Birmingham, [2]Diabetes, Hull Royal Infirmary, Hull, United Kingdom.

Background and aims: To learn from experience of exenatide in real clinical use in the UK, ABCD began a nationwide audit in December 2008. Though exenatide is not licensed for use with insulin, many contributors used the combination. We aimed to assess the extent, safety and efficacy of this off license usage.
Materials and methods: ABCD website hosted, password protected, on-line questionnaire for collection of anonymised patient data. Paired T tests compared baseline and latest weight and HbA1c. Hypoglycaemia reports were quantified.
Results: 315 contributors from 126 centres submitted data on 6717 patients - mean baseline age 54.9, HbA1c 9.47%, weight 113.83 kg, BMI 38.9 kg/m2, 55.5% male. Of these 4691 had dated baseline and latest HbA1c; 4506 dated baseline and latest weight. Latest HbA1c and weight were at a median (range) of 26.3 (6.6-164.1) and 26.1 (6.6-159.0) weeks respectively after exenatide start. Insulin treatment status was assessable in 6158/6717 (91.7%) patients. These were divided into 5 groups (see table). 2061/6158 (33.5%) were on insulin at exenatide start (groups 2-4). 1584/6158 (25.7%) continued on insulin (group 4). For those with dated baseline and latest data, the response of HbA1c and weight in the different insulin treatment groups are shown in the table. It can be seen that the addition of exenatide to insulin (group 4) was associated with significant falls of HbA1c and weight by 0.43% and 5.8 kg respectively. Insulin was stopped at the time of exenatide start in 477/2061 (23.1%) of those on insulin. Of these 325/477 (68.1%) substitution of exenatide for insulin proved highly effective with HbA1c falling by 0.69% and weight by 9 kg. However in 152/477 (31.9%) discontinuing insulin at the time of exenatide start resulted in significant deterioration in glycaemic control and restart of insulin. In total 2257/6165 (36.7%) experienced exenatide with insulin at some stage (groups 3-5). Of these 133/2257 (5.9%) experienced hypoglycaemia prior to insulin exenatide combination and 193/2257 (8.6%) after (p=0.001). However severe hypoglycaemia was reported in only 1/2257 (0.04%). 201/1584 (12.7%) of the patients who continued insulin at exenatide start (group 4) came off insulin during exenatide treatment. In this group both HbA1c and weight fell by considerable amounts: mean HbA1c by 0.81% from 9.4 to 8.59% (p<0.001) and weight by 10 kg from 116 to 106 kg (p<0.001).
Conclusion:
1. The combination of insulin with exenatide was used in 36.7% (2257/6158) patients in the ABCD nationwide exenatide audit.
2. Exenatide with insulin in real clinical use in the UK has been both safe and effective with significant reductions in both weight and HbA1c and only one reported case of severe hypoglycaemia.
3. Exenatide allowed some patients to be weaned off insulin and this group may experience a considerable improvement in glycaemic control and a large reduction in weight.

	HbA1c (%)			Weight (Kg)		
Group	Baseline HbA1c	Latest HbA1c	Fall in HbA1c	Baseline weight	Latest weight	Fall in weight
Group 1: Not on insulin (n=3576)	9.42	8.45***	0.98	114.4	109.0***	5.4
Group 2: Insulin stopped at start and stayed stopped (n=325)	9.74	9.05***	0.69	111.5	102.5***	9
Group 3: Insulin stopped at start but restarted (n=152)	9.73	9.92°	-0.18	108.5	101.3***	7.2
Group 4: Insulin continued at start (n=1584)	9.54	9.11***	0.43	112.6	106.8***	5.8

Exenatide vs. insulin aspart in patients with type 2 diabetes: results of a randomised, open-label study

B. Gallwitz[1], M. Böhmer[2], T. Segiet[3], A. Mölle[4], K. Milek[5], B. Becker[6], K. Helsberg[7], H. Petto[8], N. Peters[7], O. Bachmann[7];
[1]Department of Medicine IV, University Hospital Tübingen, Germany, [2]Diabetologist, Warburg, Germany, [3]Diabetologist, Speyer, Germany, [4]Center of Angiology and Diabetology, Dresden, Germany, [5]Diabetologist, Hohenmölsen, Germany, [6]Diabetologist, Essen, Germany, [7]Medical Department, Lilly Deutschland GmbH, Bad Homburg, Germany, [8]Eli Lilly GmbH, Vienna, Austria.

Background and aims: Cardiovascular trials suggest that hypoglycemia (hypo) may be underestimated as risk factor for type 2 diabetes (T2DM). This 26wk, randomized, open label study was designed to test if exenatide (EX) is noninferior to insulin aspart (IA) for glycemic control, and associated with a lower hypo risk in patients (pts) pretreated with metformin (MET; primary objective, hierarchical test). Pts pretreated with MET+sulfonylurea (SU) were enrolled into an additional exploratory arm.
Materials and methods: Adults with T2DM (HbA_{1c} 6.5-10.0%, BMI 25-40 kg/m^2) pretreated with MET only (confirmatory) or MET+SU (exploratory) were enrolled at 3:1 ratio. Within each arm, pts were randomized 1:1 to EX (4wks 5µg, then 10µg BID) or premixed IA 70/30 twice daily (ADA targets). For noninferiority of EX, the upper 95% CI limit of the group difference in HbA_{1c} change (EX minus IA; MMRM, MET only) needed to be <0.4%. If noninferiority was met, hypo rates (pts with ≥1 documented [BG ≤3.9 mmol/l] or severe hypo up to wk26) were compared by Kaplan-Meier analysis (overlap of 95% CIs; all pts treated). Corresponding exploratory analyses were performed for the MET+SU arm.
Results: Of 494 pts randomized (363 MET only; 131 MET+SU), 480 started study drug (MET only: EX 181/IA 173; MET+SU: EX 66/IA 60). 341 pts completed the study (MET-only: EX 135/IA 137; MET+SU: EX 31/IA 38). Compared to pts pretreated with MET only, MET+SU pts were older (mean age [95% CI]: 60 [58.2; 61.8] vs 57 [56.0; 58.1] y, and had a longer diabetes duration (8 [7.3; 9.4] vs 5 [4.6; 5.5] y). Baseline BMI (32.0 [31.3; 32.8] vs 33.2 [32.7; 33.6] kg/m^2) and HbA_{1c} (7.98 [7.85; 8.12] vs 7.88 [7.79; 7.97] %) were similar. MET+SU pts required higher insulin doses (mean final dose [95% CI]: 0.43 [0.36; 0.50] vs 0.29 [0.27; 0.32] IU/kg/d). Within each pretreatment arm, characteristics of EX and IA groups were similar. For patients pretreated with MET only, glycemic control with EX was non-inferior to IA (LS mean difference at Wk 26: 0.14; 95% CI [-0.003; +0.291]); EX was associated with lower hypo rates (Table; p<0.05). For patients pretreated with MET+SU, glycemic control with EX was inferior (+0.80 [+0.41; +1.19]). The difference in hypo rates (Table) was not significant. Body weight decreased with EX and increased with IA irrespective of pretreatment (p<0.001).
Conclusion: In pts pretreated with MET only, EX was non-inferior to IA for glycemic control and superior for control of hypoglycemia and body weight (confirmatory arm). In the small exploratory arm pretreated with MET+SU, EX was inferior for glycemic control, this might be due to more advanced disease and therefore smaller beta cell reserve.

Table: Summary of results

		Pretreated MET only (confirmatory)		Pretreated MET+SU (exploratory)	
		EX (N=181)	IA (N=173)	EX (N=66)	IA (N=60)
HbA_{1c} (%)	LSmean change, wk26	-1.0	-1.1	-0.2	-0.9

Impact of exenatide once weekly and insulin glargine on glucose control and cardiovascular risk factors in subjects with type 2 diabetes

M. Diamant[1], L.F. Van Gaal[2], S.N. Stranks[3], J. Northrup[4], D. Cao[4], K. Taylor[5], M. Trautmann[4];
[1]Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, [2]Department of Diabetology, Metabolism, and Clinical Nutrition, Antwerp University Hospital, Belgium, [3]Southern Adelaide Diabetes and Endocrine Services, Australia, [4]Eli Lilly and Company, Indianapolis, USA, [5]Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Many patients failing to achieve blood glucose control on oral agents have elevated cardiovascular (CV) risk factors including hypertension and hyperlipidaemia. We examined glycaemic control (primary endpoint, change in HbA1c) and select CV risk factors (secondary endpoints) in subjects who were randomised to receive a glucagon-like peptide-1 receptor agonist (exenatide once weekly [EQW]) or a common starter insulin (insulin glargine [IG]) for 26 weeks.
Materials and methods: A 26-week, open-label, multicountry, randomised, superiority study compared EQW to IG titrated to target in 456 subjects with type 2 diabetes (mean HbA1c 8.3 [SD 1.1] %, fasting glucose 9.8 [2.6] mmol/L, weight 90.9 [17.5] kg, diabetes duration 7.9 [6.0] years, endpoint insulin dose 31 IU/day). Randomisation was stratified by country and oral blood glucose-lowering therapy (70% metformin alone; 30% metformin plus sulphonylurea). Changes in concomitant lipid-lowering and antihypertensive medications were allowed if deemed necessary by the investigator. Post hoc assessments were performed: 1) Change in CV risk factors in subjects with abnormal baseline (defined in Table 1) and; 2) Correlations between CV risk factors and body weight.
Results: EQW and IG both reduced HbA1c significantly from baseline (-1.5 [SE 0.05] % vs. -1.3 [0.06] % respectively, treatment difference -0.16 [0.07] %, p=0.017). The majority of subjects had elevated lipids and/or blood pressure at baseline (Table 1). EQW subjects experienced small but statistically significant improvements in total cholesterol and high-sensitivity C-reactive protein (hsCRP), whereas IG subjects experienced improvements in triglycerides and alanine aminotransaminase (ALT). In both treatment groups, greater improvements in blood pressure, fasting serum lipids, ALT, and hsCRP were observed in subjects with abnormal baseline values. Subjects treated with EQW lost body weight while IG subjects gained weight (-2.6 [SE 0.2] kg vs. 1.4 [0.2] kg, treatment difference -4.0 [0.3] kg, p<0.001). Body weight change was weakly correlated with change in ALT (EQW: adjusted r=0.03, p=0.008) and SBP (IG: adjusted r=0.02, p=0.03).
Conclusion: In this 26-week study, superior improvements in HbA1c and body weight were observed with EQW treatment relative to IG. Treatment with either EQW or IG for 26 weeks resulted in small but significant changes in different surrogate markers of cardiovascular risk. Subjects with abnormal baseline CV risk factors exhibited the greatest improvements in those parameters.

Taspoglutide added to metformin provides comparable glycaemic control as insulin glargine with superior weight loss and less hypoglycaemia in type 2 diabetes: The T-emerge 5 Trial

F.J. Ampudia-Blasco[1], M. Nauck[2], M. Andjelkovic[3], E. Horton[4], M. Boldrin[5], R. Balena[3];
[1]Clinic University Hospital, Valencia, Spain, [2]Diabeteszentrum Bad Lauterberg, Bad Lauterberg im Harz, Germany, [3]F.Hoffmann-La Roche, Basel, Switzerland, [4]Joslin Diabetes Center, Boston, USA, [5]Roche Pharmaceuticals, Nutley, USA.

Background and aims: Taspoglutide is a once-weekly (QW) human GLP-1 analog in Phase 3 development for the management of type 2 diabetes (T2D). This trial evaluated a forward strategy replacing sulfonylureas (SU) by taspoglutide or insulin glargine in combination with previous metformin (MET) therapy.
Materials and methods: T-emerge 5 compared QW taspoglutide to once-daily (QD) insulin glargine (INS) in adult insulin-naïve patients with T2D inadequately controlled with MET+SU. After discontinuation of SU for 5±1 days, 1049 patients were randomized 1:1:1 to QW taspoglutide 10 mg (Taspo10), QW taspoglutide 20 mg (Taspo20; up-titrated after 4 weeks of 10 mg), or QD INS for 24 weeks. INS was adjusted using a forced titration algorithm to achieve optimal target fasting plasma glucose of 6.1 mmol/L (110 mg/dL). The primary endpoint was the change from baseline in HbA_{1c} at week 24. The analysis was conducted using the intent-to-treat population to test the non-inferiority of Taspo10 and Taspo20 with INS (using 2-sided 95% CI for HbA_{1c} difference and non-inferiority margin of 0.4%).
Results: Baseline characteristics were comparable across groups (mean values: age 58 yrs, BMI 32 kg/m^2, BW 91 kg, and HbA_{1c} 8.3%). LS mean (SE) change from baseline in HbA_{1c} was -0.8% (0.05), -1.0% (0.05) and -0.8% (0.05) for Taspo10, Taspo20 and INS groups, respectively, with both Taspo10 and Taspo20 being non-inferior to INS. Proportion of patients achieving HbA_{1c} ≤7.0% was greater for both Taspo arms compared with INS (Taspo10, 39%; Taspo20, 47%; INS, 32%). Taspo10 and Taspo20 produced significantly greater weight loss vs. INS (Figure). In addition, the proportion of patients who experienced hypoglycaemia (confirmed/unconfirmed) was significantly lower with Taspo10 (5%) and Taspo20 (6%) vs. INS (17%) (P<0.0001 for both). Serious AE incidence was similar among the groups. Withdrawals due to adverse events (AEs) were higher with Taspo vs. INS, primarily due to gastrointestinal (GI) AEs (Taspo10, 6%; Taspo20, 10%; INS, 0%).
Conclusion: Compared to daily INS, addition of once-weekly Taspo to previous MET in patients failing on MET+SU improved similarly glycaemic control with additional weight loss and less hypoglycaemia, but more GI AEs. (NCT00755287)

Effects of long term administration of miglitol and voglibose on plasma glucagon-like peptide-1 and gastric inhibitory polypeptide after a mixed meal ingestion

T. Narita[1], H. Yokoyama[2], R. Yamashita[2], M. Hosoba[1], T. Sato[1], T. Morii[1], H. Fujita[1], K. Tsukiyama[1], Y. Yamada[1];
[1]Department of Endocrinology, Diabetes and Geriatric Medicine, Akita University Graduate School of Medical Science, Akita, [2]Jiyugaoka Medical Clinic, Internal Medicine, Obihiro, Japan.

Background and aims: Recently, we have reported that a two-week administration of miglitol (M), an alpha-gucosidase inhibitor (AGI), induces prolonged and enhanced glucagon-like peptide-1 (GLP-1) and reduced gastric inhibitory polypeptide (GIP) responses after a mixed meal ingestion in Japanese type 2 diabetics (T2Ds). However, such effects of AGI on plasma incretins during long term or whether those effects of AGIs would be different according to types of AGIs (M, absorbed type; voglibose [V], non-absorbed type) have not been reported.
Materials and methods: In this multicenter, open 12-week trial, 26 and 24 Japanese T2Ds (age and HbA1c [mean]: 58.5, 59.5; 7.11 %, 7.08 %, respectively) with diet therapy and/or oral hypoglycemic agents other than AGIs were randomly assigned to receive 50 mg of M or 0.3 mg of V three times per day, respectively. We measured plasma glucose (PG), insulin (IRI), active GLP-1 and total GIP 0, 30, 60, 120 min after ingestion of a mixed meal (meal tolerance test [MTT]) at baseline and 12 weeks after administration of M or V. Active GLP-1 and total GIP levels were measured using commercially available ELISA kits (Linco Research, St Charles, MO, USA). Data are expressed as mean (SE).
Results: Baseline values of PG, IRI, GLP-1 and GIP during MTT were similar in both groups. PGs (mg/dL) at 30 and 60 min during MTT were significantly decreased both after M and V (at 30 min, 204.6 (6.4) vs. 160.0 (4.8) [M, p<0.001] and 208.6 (10.1) vs. 178.8 (7.4) [V, p<0.001]; at 60 min, 247.0 (8.6) vs. 184.2 (5.4) [M, p<0.001] and 246.0 (10.4) vs. 197.2 (7.9) [V, p<0.001]). PG at 30 min during MTT after M was significantly lower than that after V (p<0.05). IRIs at 30 and 60 min during MTT were also significantly decreased both after M and V. GLP-1 values at 60 and 120 min during MTT were significantly increased after M whereas only at 60 min value was significantly increased after V (figure). AUC (area under the curve during MTT) of GLP-1 was significantly increased after M (p<0.01) despite of marginal increase after V (p=0.059). GIPs at 30, 60 and 120 min during MTT were significantly decreased both after M and V (figure). GIPs at 30 and 60 min during MTT after M were significantly lower than those after V (figure). AUC of GIP after M was significantly lower than that after V (p<0.05). During the 12-week treatment, BMI reduction was significant after M (from 25.1 [1.0] to 24.7 [1.0], p<0.01) but not after V (from 25.6 [1.0] to 25.5 [1.0]).
Conclusions: Long term AGI administration induces increased GLP-1 and decreased GIP responses after a mixed meal ingestion in Japanese T2Ds. Absorbed type of M may have relatively strong effects modifying postprandial incretin responses compared with non-absorbed type of V. Slight but significant BMI reduction after M not but V might be attributable to these different effects on incretins.

Improved glycaemic control with once-daily insulin detemir in combination with sitagliptin/metformin vs. sitagliptin/metformin ± sulphonylurea drugs

P.A. Hollander[1], K. Rašlová[2], T.V. Skjøth[3], J. Råstam[3], J. Liutkus[4];
[1]Baylor University Medical Center, Dallas, USA, [2]Metabolicke Centrum, Bratislava, Slovakia, [3]Novo Nordisk A/S, Copenhagen, Denmark, [4]Vascular Risk Modification Clinic, Cambridge, Canada.

Background and aims: Once-daily insulin detemir (IDet) provides stable, 24 hour glucose control and is often prescribed for patients with T2D as add-on to OADs. DPP-4 inhibitors, a new class of OADs, reduce degradation of GLP-1 mobilized in response to glucose intake, thereby improving endogenous glucose-dependent insulin secretion at mealtime. This study was a randomized, open-label, parallel group, 26-week trial designed to compare the efficacy and safety of two treatment regimens comprised of IDet in combination with the DPP-4 inhibitor sitagliptin (SITA) or SITA in combination with a subjects' prior sulphonylurea (SU) regimen, if any, and both groups continuing on metformin (Met), in insulin-naïve T2D patients who were poorly controlled by their previous regimens with Met ± other OADs.
Materials and methods: Treatment was for 26 weeks with once-daily IDet + SITA (100 mg QD) + Met (at pre-trial dose ≥1000 mg) (IDet/SITA; *n*=107) but with any prior SU discontinued, or with SITA + Met ± SU (continuing each subject's pretrial SU dosing, if any) (SITA ± SU; *n*=110). Both arms contained a similar percentage of subjects (75 and 77%, IDet/SITA vs. SITA, respectively) with pre-trial SU treatment experience.
Results: Observed baseline A1C in both arms was 8.5%. Estimated mean A1C reductions of 1.44 and 0.89% were achieved (IDet/SITA vs. SITA ± SU; est. mean diff. = 0.55%, 95% CI [-0.77, -0.33], $p<0.001$); estimated final mean A1c values were 7.08 and 7.64%, respectively; 45 vs. 24% of patients reached A1C ≤7% (Adjusted Odds Ratio (OR) = 3.20, 95% CI [1.65, 6.19], $p=0.001$) and 19 vs. 10% reached A1C ≤6.5% (OR 2.23, 95% CI [0.96, 5.20], $p=0.063$). Observed FPG baselines were 9.7 mmol/L (174.8 mg/dL) and 9.8 mmol/L (176.5 mg/dL), with final mean estimated FPG values 6.1 mmol/L (109.5 mg/dL) and 8.5 mmol/L (153.5 mg/dL), respectively (IDet/SITA vs. SITA ± SU; est. mean diff. = -2.45, 95% CI [-3.01, -1.88], $p<0.001$). After 26 weeks 9-point PG profiles were significantly lower for IDet/SITA at all time points except before dinner. No major hypoglycemia occurred in either arm. Rates for minor hypoglycemia (PG <3.1 mmol/L [56 mg/dL]) were low in both treatment arms, with no statistically significant differences between arms (0.47 vs. 0.48 episodes/patient-year, IDet/SITA vs. SITA ± SU; Adjusted Rate Ratio = 0.97, 95% CI: [0.35, 2.74]; p=NS). 36% of the subjects taking IDet/SITA achieved the HbA_{1c} ≤7% target without hypoglycemia in the last 3 months of treatment vs. 20% in the SITA ± SU arm (OR = 2.47, 95% CI [1.26; 4.81], $p=0.008$). Mean IDet dose rose from 0.11 to 0.59 U/kg during the 26 weeks' treatment. Body weight and BMI decreased in both arms (-0.81 vs. -1.66 kg and -0.30 vs. -0.58 kg/m^2 in IDet/SITA vs. SITA ± SU, respectively; p=NS). Data analysis of the subgroup who received SU pre-trial mirrored the data presented here for the full analysis set.
Conclusion: Glucose control was significantly more improved in patients on once-daily IDet/SITA vs. patients on SITA ± SU (Met in both arms) with

larger reductions in A1c and FPG occurring in the IDet/SITA arm. This was achieved with modest weight reductions and low hypoglycemia in both arms. These data support the use of once-daily IDet in combination with a DPP-4 inhibitor, SITA, and Met, with SU discontinued, as a safe and effective treatment option for insulin-naïve patients with T2D.

Short-term effects of bed-time insulin versus GLP-1 analogue on resting energy expenditure in patients with type 2 diabetes
C. Gonzalez, S. Salandini, A. Pierreisnard, M.-C. Beauvieux, H. Gin, V. Rigalleau;
USN, Hopital Haut-Lévêque, Pessac, France.

Background and aims: GLP-1 analogues can be used instead of bed-time insulin therapy for poorly controlled type 2 diabetic (T2D) patients, with opposite influences on body weight. Beside the effect of GLP-1 on energy intake, it is not known whether changes of the Resting Energy Expenditure (REE) contribute to these distinct weight courses. We compared the early (first days) effects of both treatments on REE in T2D patients.
Materials and methods: Twenty-five T2D patients (8 women, 17men) poorly controlled despite maximal oral therapy, were included: 8 patients received GLP-1 analogue (exenatide® 5 µg twice-a-day); 17 received bed-time insulin analogue (Glargine® or Detemir®, initial dose 0.2UI/kg). REE was measured by indirect calorimetry before the first injection (Day0) and during two days (Day1 and 2) after initiating the treatments. Respiratory exchanges were monitored using a Sensor Medics Vmax 29N apparatus: VCO2 and VO2 were determined on 30 minutes intervals from 8 a.m. to 8h30 a.m., before breakfast, and REE was calculated according to Weir's equation. Body weight was assessed three months later.
Results: The two groups did not differ for age (GLP-1 group: 57±10 years; Insulin group: 56±10 years), gender, body weight (GLP-1: 90.7±10.0 kg; Insulin: 91.2±15.2 kg); HbA1c (GLP-1: 10.1±0.8%; Insulin: 9.4±1.3%), fasting plasma glucose level (GLP-1: 210 ± 85 mg/dl; Insulin: 210±46 mg/dl) and initial REE (Day0: GLP-1: 1821±240 kcal/24h; Insulin: 1883±363 kcal/24h). On insulin treatment, REE decreased by -3.5 % after the first injection (Day1:1816±386 kcal/24h, p=0.07 vs Day0) and by -5.8 % after the second injection (Day2: 1774±333 kcal/24h, p=0.03 vs Day0). REE was unchanged on GLP-1 analogue treatment (Day1:1842±255 kcal/24h, Day2:1798±240 kcal/24h, both NS vs Day0). Body weight increased after three months of insulin analogue therapy (M3: 92.2±15.2 kg vs Day0: 91.2 kg±15.6; p=0.08) whereas it decreased on GLP-1 analogue (M3:86.7±9.2kg vs 90.7±10.0; p=0.06), with significantly different body weight changes at three months (p=0.002).
Conclusion: REE decreases early after the introduction of insulin therapy, whereas it is not affected by the GLP-1 analogue. These different effects on REE probably contribute to the opposite weight changes with these treatments.

Efficacy of dapagliflozin as monotherapy administered in the morning or evening to treat type 2 diabetes mellitus
A. Salsali[1], W. Tang[1], J.F. List[1], E. Ferrannini[2];
[1]Bristol Myers Squibb, Princeton, USA, [2]University of Pisa School of Medicine, Italy.

Background and aims: Dapagliflozin is a highly selective and reversible inhibitor of the renal sodium glucose co-transporter-2, being developed as an oral antidiabetic agent.
Materials and methods: We report here data from a 24-week randomized, double-blind, phase 3 trial of dapagliflozin administered in the morning or the evening to treatment-naïve type 2 diabetes mellitus patients (study ID: MB102013). Patients (n=485) with HbA1c 7.0-10% were randomized equally to receive placebo, or dapagliflozin 2.5, 5 or 10 mg, once-daily in the morning (main cohort) or evening (exploratory cohort). All patients received diet/exercise counselling. Efficacy measures included change from baseline in HbA1c, fasting plasma glucose (FPG) and body weight at week 24. Adverse events were assessed throughout the study. Patients were actively monitored for signs/symptoms suggestive of urinary tract infections (UTIs) and genital infections and MedDRA (Medical Dictionary for Regulatory Activities, version 11.1) preferred terms relating to these were prospectively defined.
Results: Reductions in mean HbA1c and FPG were seen in all treatment groups and were statistically significant in 5 and 10 mg dapagliflozin arms of the main cohort (Table). Mean body weight decreases were greater with all dapagliflozin doses than in placebo, although not reaching statistical significance. Efficacy with morning and evening dose of dapagliflozin was similar when compared to placebo. There were no clinically meaningful changes in serum electrolytes, creatinine, or cystatin-C in any treatment arm. Signs/symptoms/other reports suggestive of UTI and genital infection were more frequent with dapagliflozin than placebo (4.6-12.5% in dapagliflozin arms vs 4.0% with placebo for UTI; and 2.6-12.9% in dapagliflozin arms vs 1.3% with placebo for genital infection). The reported signs and symptoms of UTI and genital infection were resolved with standard care and rarely led to study discontinuation. There was no increase in hypoglycemia with dapagliflozin and hypoglycemic events were well balanced in all treatment arms including placebo. Overall rate of adverse events was similar between the morning and evening dosing groups. There were no reports of nocturia in the main morning cohort and 1, 2, and 3 patients with nocturia in dapagliflozin 2.5, 5 or 10 mg evening dose arms, respectively.
Conclusion: Dapagliflozin is equally efficacious with morning or evening dosing with no notable difference in the number or type of adverse events between the two cohorts. Treatment with dapagliflozin resulted in clinically meaningful decreases in HbA1c and FPG in type 2 diabetes mellitus patients along with a favorable effect on weight.

Dapagliflozin: an effective treatment option in patients with type 2 diabetes across stages of disease

S. Parikh[1], J. Sugg[1], L. Ying[2], J.F. List[2];
[1]AstraZeneca, Wilmington, [2]Bristol-Myers Squibb, Princeton, USA.

Background and aims: Dapagliflozin, a selective inhibitor of the renal sodium glucose co-transporter 2 (SGLT2), helps lower excess glucose levels in an insulin-independent manner by increasing urinary glucose excretion. We analysed data from 3 double-blind, randomised, placebo-controlled trials of dapagliflozin in patients with inadequate glycaemic control at different stages of type 2 diabetes (T2DM), as reflected by their treatment regimens.
Materials and methods: Patients with T2DM were treated with dapagliflozin 2.5, 5 or 10 mg or placebo as monotherapy (study MB102013; N = 485 [main cohort N = 274]), as an add-on to metformin (MB102014; N = 546) and as an add-on to insulin with or without up to 2 oral anti-diabetic drugs (AZ006; N = 807). The primary end point for all trials was change in HbA1c at Week 24.
Results: Significant improvements in the glycaemic measures of HbA1c and fasting plasma glucose (FPG) were observed with dapagliflozin (Table) regardless of T2DM stage and background medication and with no increase in major hypoglycaemia. The need for rescue therapy with anti-diabetic agents (monotherapy and metformin studies) or insulin for failing to achieve prespecified glycaemic targets was reduced with dapagliflozin. Weight loss was seen in all studies, which reached statistical significance for patients in the metformin and insulin studies in dapagliflozin treatment groups compared to placebo. Adverse events (AE), serious AEs and study discontinuations were similar across all groups, although active solicitation revealed increased reports of signs, symptoms and events suggestive of genital infection in dapagliflozin groups. There were increased reports suggestive of urinary tract infection with dapagliflozin in the monotherapy and insulin trials but not in the metformin trial.
Conclusion: Dapagliflozin produced significant improvement in glycaemic control in patients at various stages in the progression of T2DM, from treatment-naïve to those on insulin with or without oral anti-diabetic agents. Dapagliflozin, due to its insulin-independent mechanism, is a potential therapy to improve glycaemic control and body weight in patients with T2DM across stages of disease.

Efficacy and safety of dapagliflozin in patients with type 2 diabetes mellitus and inadequate glycaemic control on glimepiride monotherapy

K. Strojek[1], V. Hruba[2], M. Elze[3], A. Langkilde[4], S. Parikh[5];
[1]Silesian Medical University, Zabrze, Poland, [2]AstraZeneca, Prague, Czech Republic, [3]ClinResearch, Koeln, Germany, [4]AstraZeneca, Mölndal, Sweden, [5]AstraZeneca, Wilmington, USA.

Background and aims: In management of patients with type 2 diabetes mellitus (T2DM), progressive deterioration of glycaemic control is commonly observed, requiring treatment intensification with additional drug therapy. Dapagliflozin (DAPA), a selective inhibitor of sodium-glucose co-transporter 2 that inhibits renal glucose reabsorption, has been shown to reduce hyperglycaemia and body weight in patients with T2DM without a significantly increased risk of hypoglycaemia. We assessed efficacy, safety and tolerability of DAPA as add-on to glimepiride in patients with uncontrolled T2DM.
Materials and methods: This 24-week (wk) randomized, double-blind, placebo-controlled, parallel-group multicentre trial (D1690C00005) in Europe/Asia-Pacific enrolled patients with T2DM uncontrolled on at least half the maximum recommended dose of sulfonylurea alone (HbA1c 7.0-10.0%). A total of 597 adult subjects were randomized to DAPA (2.5, 5, or 10 mg/d) or placebo (PLA) added to open-label glimepiride 4 mg/d for 24 wk. Primary endpoint was change from baseline in HbA1c at 24 wk. Secondary endpoints included changes in other glycaemic parameters and body weight. Interim safety data are also described.
Results: At 24 wk, DAPA showed dose-dependent significant reductions in HbA1c from baseline vs PLA (Table). DAPA showed weight loss relative to PLA at wk 24 (-0.46, -0.84, -1.54 kg for DAPA 2.5, 5,10 mg, respectively) which was statistically significant for DAPA 5 and 10 mg treatment groups. DAPA 5 and 10 mg caused significant improvements in oral glucose tolerance test (OGTT) response and in fasting plasma glucose (FPG) at wk 24. Compared with PLA, significantly more DAPA 5 and 10 mg-treated patients achieved HbA1c <7.0% at wk 24. Adverse events (AEs) were reported in 47%, 52%, 48%, and 50% of patients receiving PLA and DAPA 2.5, 5, 10 mg, respectively; frequency of drug-related AEs was similar across all treatment groups. Actively solicited events suggestive of urinary tract infections were 6.2%, 3.9%, 6.9% and 5.3% in PLA and DAPA 2.5, 5, 10 mg, respectively. No AE of kidney infection was reported. Actively solicited events suggestive of genital infections were 0.7%, 3.9%, 6.2% and 6.6% in PLA and DAPA 2.5, 5, 10 mg, respectively. No cases of genital tract infection led to treatment discontinuation. Hypoglycaemic events were 4.8%, 7.1%, 6.9% and 7.9% in PLA and DAPA 2.5, 5, 10 mg groups, respectively. No clinically meaningful mean changes from baseline in serum creatinine or electrolytes were observed. Adjusted mean changes from baseline at wk 24 in seated systolic/diastolic blood pressure were -1.2/-1.4, -4.7/-1.1, -4.0/-1.7 and -5.0/-2.8 mmHg for PLA, and DAPA 2.5, 5,10 mg, respectively.
Conclusions: DAPA added to glimepiride in T2DM patients uncontrolled with sulphonylurea monotherapy significantly improves HbA1c, reduces weight and is well tolerated.

Effect of dapagliflozin, a novel insulin-independent treatment, over 48 weeks in patients with type 2 diabetes poorly controlled with insulin

J.P.H. Wilding[1], V. Woo[2], A. Pahor[3], J. Sugg[4], A. Langkilde[4], S. Parikh[5];
[1]Department of Medicine, University of Liverpool, United Kingdom, [2]University of Manitoba, Winnipeg, Canada, [3]AstraZeneca, Wedel, Germany, [4]AstraZeneca, Mölndal, Sweden, [5]AstraZeneca, Wilmington, USA.

Background and aims: Escalating insulin doses to achieve glycaemic targets in type 2 diabetes mellitus (T2DM) increases risk of weight gain, fluid retention and hypoglycaemia, often presenting a therapeutic dilemma. Dapagliflozin, a selective inhibitor of sodium glucose co-transporter 2 (SGLT2), reduces glucose levels in T2DM patients in an insulin-independent manner by inducing urinary glucose excretion. Resulting caloric loss may also help prevent weight gain in insulin-treated patients.
Materials and methods: To determine efficacy and safety of dapagliflozin in T2DM poorly controlled with insulin, patients were randomised to placebo, 2.5, 5, or 10 mg dapagliflozin added to unchanged background insulin therapy with or without concomitant oral antidiabetic drugs (Trial D1690C00006). Primary outcome measure was change from baseline in HbA1c at week (wk) 24 (LOCF). Patients completing the 24-wk primary efficacy phase continued in a 24-wk site- and subject-blinded extension phase.
Results: A total of 808 patients were randomised. Mean baseline values were: HbA1c, 8.5%; fasting plasma glucose (FPG), 178 mg/dL; body weight (BW), 94 kg; insulin dose, 77 IU/day. Of 711 patients who completed the primary efficacy phase, 676 completed 48 wks of double-blind treatment. Significant reductions in HbA1c, FPG, BW and insulin dose were observed with dapagliflozin relative to placebo in primary efficacy phase with no clinically relevant increase in hypoglycaemia. Reductions in glycemic parameters and BW were sustained over 48 wks. Insulin requirements over the 48 wks continued to increase with placebo but not in dapagliflozin groups. Overall, adverse events (AEs), serious AEs, and study discontinuations were comparable across groups. Active solicitation revealed increased reports of signs and symptoms suggestive of urinary (7.9-10.8% vs 5.1% for placebo) and genital (6.4-10.7% vs 2.5% for placebo) tract infection with dapagliflozin, most of which occurred during first 24 wks, were generally mild and responded to routine management. Two cases of pyelonephritis (1 each in 2.5 and 5 mg groups) responded to antibiotic therapy and did not lead to discontinuation. There were no discontinuations due to hypoglycaemia. There was a trend of small mean decreases in systolic blood pressure, without increased frequency of orthostatic hypotension, in dapagliflozin groups.
Conclusion: Once-daily oral dapagliflozin improved glycaemic control without an increase in daily insulin requirements and led to weight loss in patients with T2DM poorly controlled with insulin over a 48-wk treatment period. Attenuating the cycle of escalating insulin dose and weight gain represents an improvement for this patient population.

Dapagliflozin lowered rate of insulin uptitration/study discontinuation from lack of glycaemic control in 48-week study of type 2 diabetes patients poorly controlled on insulin therapy

N.G. Soler[1], J.P.H. Wilding[2], V. Woo[3], A. Pahor[4], J. Sugg[5], A. Langkilde[6], S. Parikh[5];
[1]Springfield Diabetes & Endocrine Center, Springfield, USA, [2]University of Liverpool, United Kingdom, [3]University of Manitoba, Winnipeg, Canada, [4]AstraZeneca, Wedel, Germany, [5]AstraZeneca, Wilmington, USA, [6]AstraZeneca, Mönndal, Sweden.

Background and aims: In patients with poorly controlled type 2 diabetes (T2DM) receiving insulin (INS), the clinical utility of escalating INS doses

to achieve glycaemic control is often limited by associated weight gain, fluid retention, hypoglycaemia and patient acceptance. Dapagliflozin (DAPA), a selective inhibitor of sodium-glucose cotransporter 2 in development for T2DM treatment, increases renal excretion of glucose and lowers blood glucose via an INS-independent mechanism. The coadministration of DAPA with INS can potentially attenuate escalating INS doses and associated side effects.

Materials and methods: Patients with poorly controlled T2DM (n=808; mean baseline HbA1c 8.53%) were randomized to placebo (PLA), 2.5, 5, or 10 mg/d DAPA in addition to background INS (mean baseline dose 77 IU/d) ± other oral antidiabetic drugs. Primary glycaemic and safety endpoints have been reported separately; here we report time to study discontinuation or INS up-titration due to lack of glycaemic control (DISC-UP) for up to 48 weeks (wk) of continued centre- and patient-blinded treatment. INS was up-titrated if HbA1c was >8% or fasting plasma glucose was >9.9mmol/L from 24-48 wk. Weight gain, peripheral oedema and DISC due to hypoglycaemia and other causes were also assessed.

Results: Time to reach DISC-UP was substantially prolonged in all DAPA + INS groups vs PLA + INS (figure). At 48 wk, the proportion of patients with DISC-UP was 42.8% in the PLA + INS group vs 21.7%, 15.6% and 15.3% in the DAPA + INS groups, with the greatest difference seen between the DAPA 10 mg + INS vs PLA + INS groups (−27.5%; 95% CI −35.9 to −19.1%). Patients receiving DAPA maintained glycaemic control and sustained reductions in body weight from 24-48 wk compared with placebo. At 24 wk, the proportion of patients with weight loss >3% was 10.4% in the PLA + INS group vs 17.7-23.3% in the DAPA + INS groups. Corresponding values at 48 wk were 10.4% and 21.6-24.5%, respectively. The frequency of peripheral oedema was 7.6% in the PLA + INS group vs 4%, 2.4% and 4.6% in the DAPA + INS groups. The frequency of DISC due to adverse events (AEs) in the PLA + INS group was 4.6% vs 3.5%, 7.1%, and 5.1% in the DAPA + INS groups, respectively. Corresponding values for DISC due to serious AEs were 1.5%, 1%, 2.4% and 2.6%, respectively. There were no DISCs due to hypoglycaemia.

Conclusion: Over 48 wk, DAPA treated patients were less likely to require DISC-UP due to poor glycaemic control. This insulin sparing effect of DAPA was further demonstrated by an increased frequency of weight loss and a reduced frequency of peripheral oedema over time.

Canagliflozin, an inhibitor of sodium glucose co-transporter 2, improves glycaemic control, lowers body weight, and improves beta cell function in subjects with type 2 diabetes on background metformin

J. Rosenstock[1], D. Polidori[2], Y. Zhao[3], S. Sha[3], D. Arbit[3], K. Usiskin[3], G. Capuano[3], W. Canovatchel[3];
[1]Dallas Diabetes and Endocrine Center, Dallas, [2]Johnson & Johnson, La Jolla, [3]Johnson & Johnson, Raritan, USA.

Background and aims: Inhibition of sodium glucose co-transporter 2 (SGLT2) is being studied as a novel modality of treatment for type 2 diabetes mellitus (T2DM). We therefore sought to evaluate the safety, tolerability, and efficacy of canagliflozin (CANA, JNJ-28431754/TA-7284), a potent inhibitor of SGLT2, in subjects with T2DM with inadequate glycemic control on background metformin therapy. Since loss of beta cell function (BCF) underlies the progressive deterioration of glycemic control in T2DM, we also assessed the effect of CANA on a measure of BCF.

Material and methods: In a double-blind, placebo (PBO)-controlled, dose-ranging study, subjects (N=451) were randomized to PBO; CANA 50, 100, 200, 300 mg once daily (OD); 300 mg BID; or sitagliptin (SITA) 100 mg OD for 12 weeks. BCF was assessed using HOMA2-B% calculated from plasma glucose (PG) and C-peptide concentrations at week 12.

Results: Mean baseline characteristics (age 53 years, HbA_{1c} 7.7%, fasting plasma glucose [FPG] 9.0 mmol/l, BMI 31.5 kg/m^2) were similar across treatment groups. A significant increase in urinary glucose (UG)/creatinine in all CANA doses was observed. At week 12, the reductions from baseline in FPG and HbA_{1C} were statistically significant for all CANA arms and for SITA compared with PBO, with maximal/similar decreases at CANA 300 mg OD and BID doses (Table). Significant, dose-related weight reductions vs PBO were seen across all CANA arms but not with SITA (Table). Significant improvements in HOMA-2B% were seen in subjects treated with 100 mg of CANA and greater (Table). In general, adverse events (AEs) were transient, mild to moderate in intensity, and balanced across arms except for an increase in symptomatic genital infections that were non dose-dependent: 3-8% in CANA arms, 2% in PBO, and 2% in SITA. Similar incidences of discontinuations due to AEs and serious AEs across arms were observed. Urinary tract infections were reported in 3-9% of CANA arms, without dose-dependency, 6% of PBO, and 2% of SITA. Hypoglycemia was reported in 0-6% of CANA arms, without dose-dependency, 2% of PBO, and 5% of SITA. In CANA arms, after 12 weeks of treatment, no safety signals in laboratory studies, ECG, or vital signs were observed.

Conclusion: In subjects with T2DM with mild to moderate hyperglycemia on metformin background therapy, adding CANA was generally well tolerated, provided clinically meaningful HbA_{1c} reductions, reduced body weight, and led to suggestive improvements in BCF.

Canagliflozin, a novel inhibitor of sodium glucose co-transporter 2, increases 24-hour urinary glucose excretion and reduces body weight in obese subjects over 2 weeks of treatment

T. Sarich[1], D. Devineni[1], A. Ghosh[1], D. Wexler[1], K. Shalayda[1], J. Blake[1], M. Saraiva[1], M.J. Gutierrez[2], D. Polidori[1], K. Demarest[1], P.L. Rothenberg[1];
[1]Pharmaceutical Research & Development, Johnson & Johnson, Raritan, [2]Comprehensive Phase One, Miramar, USA.

Background and aims: Sodium glucose co-transporter 2 (SGLT2) inhibition is considered a promising new approach for the treatment of patients with type 2 diabetes. This phase 1 study aimed to assess the pharmacodynamics and safety of canagliflozin (CANA; JNJ-28431754/TA-7284), an inhibitor of SGLT2, in obese subjects, including some with impaired fasting glucose (IFG) or impaired glucose tolerance (IGT).

Materials and methods: In a double-blind, ascending, multiple-dose inpatient study, 80 obese subjects (40 women) were randomized to CANA (30, 100, 300, or 600 mg daily [OD] or 300 mg BID) or placebo (PBO) for 14 days. Subjects followed a fixed weight-maintaining diet 15 days prior to dosing until the end of the study. IFG (5.5 mmol/l ≤ fasting plasma glucose [FPG] < 6.93 mmol/l) and/or IGT (plasma glucose [PG] 2 h after a morning meal of

7.7-10.95 mmol/l) was present in 31 subjects. Renal threshold for glucose excretion (RT_G) was calculated from urinary glucose excretion (UGE), glomerular filtration rate, and PG.

Results: At baseline, subjects had a median age of 43 years (range, 21-59), a BMI of 33 kg/m^2 (range, 30-39), and an FPG of 5.12 mmol/l (range, 3.14-7.26). CANA significantly increased 24-h UGE (UGE_{24h}) on days 1-14 (Table), but there were no significant changes in FPG, mean 24-h PG, or insulin levels. Body weight decreased over the 14 days. Self-reported appetite and satiety measures did not change significantly.

	PBO	CANA				
Mean (SD)	n=20	30 mg OD n=12	100 mg OD n=12	300 mg OD n=12	600 mg OD n=12	300 mg BID n=12

[a]p<0.0001; [b]p<0.01.

CANA decreased RT_G in a dose-dependent manner, with maximal effect on lowering of the RT_G to 3.5±0.9 mmol/l. In subjects with IFG and /or IGT on day -1, (n=31), treatment with CANA (n=22, all doses pooled) produced a significant reduction in 24-h mean PG (MPG) from 6.1±0.52 mmol/l on day -1 to 5.6 ±0.48 mmol/l on day 14 (p<0.05) compared with a corresponding change from 6.1±0.66 mmol/l to 5.9±0.77 mmol/l (p>0.05) after PBO. CANA was generally well tolerated, with no hypoglycemia. Adverse events were transient and mild to moderate in severity. The most frequently reported treatment-emergent adverse events were mild gastrointestinal disorders (20% in PBO and 0-50% across CANA dose groups). There were no clinically meaningful changes in urine volume or frequency, vital signs, ECGs, or laboratory tests.

Conclusion: CANA was well tolerated and increased 24-h UGE, decreased RT_G, and reduced body weight in obese healthy subjects. In addition, the data suggest that CANA is effective in reducing MPG in patients with IFG and/or IGT.

875

Canagliflozin lowers the renal threshold for glucose excretion in lean, obese and type 2 diabetic subjects

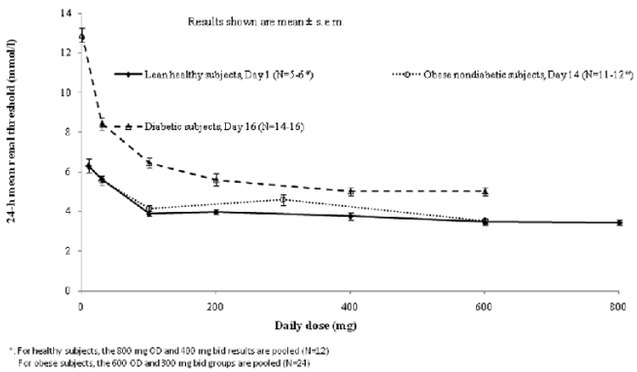
D. Polidori[1], S. Sha[2], T. Sarich[2], D. Devineni[2], P.L. Rothenberg[2];
[1]Johnson & Johnson, La Jolla, [2]Johnson & Johnson, Raritan, USA.

Background and aims: Urinary glucose excretion (UGE) can be approximated by a threshold relationship in which almost no glucose is excreted when plasma glucose (PG) concentrations are below the renal threshold for glucose excretion (RT_G), and the rate of UGE increases with PG when PG exceeds RT_G. The value of RT_G is dependent on the capacity of renal glucose transporters; pharmacological inhibitors of the transporters reduce RT_G. We aimed to determine the effects of canagliflozin (CANA; JNJ-28431754/TA-7284), an inhibitor of sodium glucose co-transporter 2 (SGLT2), on RT_G in healthy lean and obese subjects and subjects with type 2 diabetes (T2DM).

Materials and methods: Data from 3 clinical studies assessing the safety, tolerability, and pharmacodynamics of CANA were used. In study 1, lean males (BMI=20-30 kg/m^2) were treated with 1 dose of 10-800 mg or 400 mg BID CANA (n=6/group). In study 2, obese otherwise healthy subjects (BMI=30-39 kg/m^2) were treated with 30-600 mg once daily (OD) or 300 mg BID CANA (n=12/group) for 2 weeks. In study 3, subjects with T2DM were treated with 30-400 mg OD or 300 mg BID CANA (n=14-16/group) for 2 weeks. 24-h PG profiles, creatinine clearance (to estimate GFR), and UGE over 6 time intervals were measured. RT_G was determined from these measurements by assuming a threshold relationship between UGE and PG and determining the value of RT_G so that UGE calculated from the threshold approximation equals the measured UGE. This approach extends methods used for renal thresholds of other analytes by accounting for the dynamic changes in PG. 24-h mean RT_G (MRT_G) was calculated from RT_G values in each interval.

Results: CANA was well tolerated in the 3 studies with no observed hypoglycemia. Adverse events were transient and mild to moderate in severity. Urine volume, electrolyte excretion, renal function, and lab safety values did not change meaningfully. The method for determining RT_G provided highly reproducible results in placebo-treated T2DM subjects (within-subject CV <3%). CANA dose-dependently reduced RT_G; maximally effective doses (>200 mg OD in lean, >300 mg OD obese) reduced MRT_G to 3.5±0.4 mmol/l (mean±SD) in lean and 3.5±0.6 mmol/l in obese subjects (Figure). In subjects with T2DM, MRT_G was elevated before CANA (13.8±1.6 mmol/l vs commonly reported values of 10-11 mmol/l in healthy subjects), consistent with reports of increased renal glucose reabsorption in T2DM, and CANA dose-dependently reduced MRT_G to a minimum of 5.2±0.9 mmol/l at doses 200 mg. Maximally effective doses maintained maximal suppression of RT_G for the full 24-h period; with lower doses, RT_G rose from the nadir in later intervals.

Conclusion: RT_G in T2DM subjects before treatment was higher than often quoted values of 10-11 mmol/l. CANA dose-dependently decreased RT_G in all 3 studies and values in subjects with T2DM were modestly higher than nondiabetic subjects given the same doses. CANA reduces RT_G in T2DM subjects to ~5 mmol/l, a level not predicted to increase the risk of hypoglycemia.



876

Canagliflozin, a novel inhibitor of sodium glucose co-transporter 2, improved glucose control in subjects with type 2 diabetes: Results of a phase 1b study

P.L. Rothenberg[1], D. Devineni[1], A. Ghosh[1], D. Polidori[2], M. Hompesch[3], S. Arnolds[4], L. Morrow[3], H. Spitzer[4], J. Blake[1], D. Wexler[2], Y. Tan[2], K. Smulders[5], K. Demarest[5], S. Sha[5];
[1]Pharmaceutical Research and Development, Johnson & Johnson Pharmaceuticals, Raritan, USA, [2]Pharmaceutical Research and Development, Johnson & Johnson Pharmaceuticals, La Jolla, USA, [3]Profil Institute for Clinical Research Inc., Chula Vista, USA, [4]Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, [5]Johnson & Johnson Pharmaceuticals, Raritan, USA.

Background and aims: Inhibition of renal sodium glucose co-transporter 2 (SGLT2) is a promising new approach for treating type 2 diabetes mellitus (T2DM). This study evaluated the safety, tolerability, and pharmacodynamic effects of canagliflozin (CANA, JNJ-28431754/TA-7284), a novel SGLT2 inhibitor, in subjects with T2DM. The effects of CANA on urinary glucose excretion (UGE), renal threshold for glucose excretion (RT_G), plasma glucose (PG), body weight (BW), and beta cell function (BCF) were assessed.

Materials and methods: In this double-blind, multiple-dose study, subjects with T2DM discontinued their anti-hyperglycemic medications for 2 weeks and were then randomized to 2 weeks of treatment with CANA 30, 100, 200, 400 mg daily (OD) or 300 mg BID, or placebo (PBO) while domiciled at study centers and maintaining an isocaloric diet. Subjects were domiciled from day -2 before treatment until 4 days after final treatment. At pretreatment baseline (day -1) and at day 16, UGE, PG, fasting plasma glucose (FPG), C-peptide, and RT_G (calculated from UGE, PG, and GFR) were measured. BCF was assessed using the calculated insulin secretion rate (ISR) at 10 mM PG, determined from a model-based method using the frequently measured PG and C-peptide concentrations.

Results: 97 subjects (70 M/27 F; mean age 53 years, weight 91.8 kg, BMI 30.88 kg/m^2, HbA_{1C} 8%) were randomized to CANA (5 doses) or PBO. CANA treatment increased UGE and decreased RT_G in a dose-dependent manner (Table). CANA reduced 24-h PG, FPG, and BW (by approximately 1-1.5 kg >PBO). BCF also improved in subjects treated with ≥100 mg of CANA

(Table). Adverse events were transient, mild to moderate in intensity, and balanced across treatment groups; 1 episode of vaginal candidiasis occurred in a CANA-treated subject. CANA treatment did not cause hypoglycemia, consistent with the RT_G with CANA remaining above a hypoglycemic threshold. There were no clinically meaningful changes in urine volume, electrolyte excretion, renal function, or routine lab safety test values.

Conclusion: In subjects with T2DM, CANA lowered RT_G, lowered PG concentrations without causing hypoglycemia, reduced BW, and also improved BCF. In this study, CANA was well tolerated. If this profile is demonstrated in further studies, CANA could be a useful choice for treating T2DM.

The potent and highly selective sodium-glucose co-cransporter (SGLT-2) inhibitor BI 10773 is safe and efficacious as monotherapy in patients with type 2 diabetes mellitus

E. Ferrannini[1], L.J. Seman[2], E. Seewaldt-Becker[3], S. Hantel[3], S. Pinnetti[3], H.-J. Woerle[4];
[1]Medicine, University of Pisa, Italy, [2]Clinical Research, Boehringer-Ingelheim Pharmaceuticals, Inc, Ridgefield, USA, [3]Clinical Operations and BDM, Boehringer Ingelheim GmbH & Co. KG, Ingelheim, Germany, [4]Medicine, Clinical Development and Medical Affairs, Boehringer Ingelheim GmbH & Co. KG, Ingelheim, Germany.

Background and aims: The aim of this randomized double-blind, placebo (PBO)-controlled, parallel-group comparison study was to investigate the efficacy and safety of BI 10773 for 12 weeks in patients with T2DM and insufficient glycemic control.

Materials and methods: A total of 408 patients (baseline means [standard deviation]: HbA_{1c} 7.9 [0.8]%, age 57.5 [9.8] years, body mass index 29.0 [4.6] kg/m^2) who were treatment naive or had undergone a 4-week washout period, were randomized to 12 weeks of double-blind treatment with BI 10773 5, 10, 25 mg qd, PBO, or to open-label metformin (MET) 1000 mg bid or max. tolerated dose The primary endpoint was the change in HbA_{1c} from baseline after 12 weeks of treatment.

Results: After 12 weeks, BI 10773 showed a dose-dependent and statistically significant reduction in FPG and HbA_{1c}, compared with PBO (Table). Patients on BI 10773 25 mg qd showed a comparable reduction in FPG and HbA_{1c} to those on MET. There was a significant reduction in body weight (BW) by ~2 kg on BI 10773, 0.75 kg on PBO, and 1.32 on MET. Compared with PBO, mean BW reductions were statistically significant for all BI 10773groups ($p<0.001$), but not for MET. The number of adverse events (AEs) was comparable among treatment groups (32.9% in PBO group, 38.8% in MET group, 29.1% in BI 10773 groups). Most frequently reported AEs (>2%) in the BI 10773 groups (average of AEs incidence of all BI doses) included pollakiuria (3.3% *vs* 0% in PBO), thirst (3.3% *vs* 0% in PBO) and nasopharyngitis (2.0% *vs* 1.2% in PBO). Frequency of urinary tract infection was low with BI 10773 (1.2%) and comparable to PBO (1.2 %) and MET (1.3%). Incidence of genital infections was low; mycosis was reported in 0.8% and pruritus in 1.2% on BI 10773 but none on PBO or MET. Six patients experienced at least 1 serious AE, of which none was drug related. (1.2 %vs 0% vs. 3.8 % Bi10773, PBO and MET, respectively).

Conclusion: In patients with T2DM, once daily administration of BI 10773, demonstrated a dose-dependent clinically meaningful reduction in glycemic control, comparable to those of metformin. Furthermore BI 10773 was associated with a clinically meaningful reduction in body weight. and showed a favourable safety profile.

	PBO	BI 5mg qd	BI 10mg qd	BI 25mg qd	PBO	MET

PS 80 Type 2 diabetes mellitus: new therapies

878

Increased secretion of GLP-1 mediated by a newly discovered ligand for GPR119

K.B. Hansen[1,2], F.K. Knop[3], N.W. Andersen[4], T.A. Diep[4], M.M. Rosenkilde[5], J.J. Holst[2], H.S. Hansen[4];
[1]Department of Clinical Physiology, Glostrup Hospital, University of Copenhagen, Glostrup, [2]Department of Biomedical Sciences, Faculty of Health Sciences, University of Copenhagen, [3]Department of Internal Medicine F, Gentofte Hospital, University of Copenhagen, Hellerup, [4]Department of Pharmacology and Pharmacotherapy, Faculty of Pharmaceutical Sciences, University of Copenhagen, Copenhagen, [5]Department of Neuroscience and Pharmacology, Faculty of Health Sciences, University of Copenhagen, Denmark.

Background and aims: GPR119 is a G protein-coupled receptor expressed in pancreatic beta cells and the L-cells in the gastrointestinal tract in humans. In the intestine, activation of GPR119 results in the release of glucagon-like peptide-1 (GLP-1), which has been shown to improve glucose homeostasis through several mechanisms: e.g. stimulation of glucose-induced insulin secretion, inhibition of glucagon secretion and reduction of food intake. In search for activators of the GPR119 receptor our group recently identified a naturally occurring ligand with high affinity for the receptor (EC50 <1 μM), designated *XX* (patent protection; name of compound will be official at the Annual Scientific Meeting of EASD 2010). We aimed to investigate the impact of *XX* on endogenous GLP-1 secretion in healthy subjects.
Materials and methods: Six healthy Caucasian male subjects (age: 23±2 years (mean±SEM); BMI: 23±1 kg/m^2, fasting plasma glucose: 5.2±0.1 mM, HbA_1c: 5.2±0.04%) were investigated in a randomised single-blinded cross-over study. The subjects were given four different solutions on four different days using *glycerol* as vehicle: A) *XX*+*glycerol* (50 ml), B) *glycerol,* C) *XX*+*glycerol* and glucose (10 g), and D) *glycerol* and 10 g glucose. To prevent degradation in the stomach the solutions were delivered to the proximal jejunum through a tube placed distally to the ligament of Treitz. Plasma GLP-1, insulin and glucose were measured for four hours following delivery.
Results: The solution of *XX* (day A) elicited a significant greater initial GLP-1 response compared to *glycerol* (day B) ($AUC_{0\text{-}30\ min}$: 98±33 *vs.* -39±21 pM×30 min, p=0.036). We observed a significant greater initial plasma insulin response following delivery of *XX* (day A) compared to *glycerol* (day B) ($AUC_{0\text{-}30\ min}$: 809±168 *vs.* 321±104 pM×30 min, p=0.037). When the two solutions were administered along with glucose (day C and D) trends toward increased initial GLP-1 and insulin responses were observed.
Conclusion: These data show that *XX* induces secretion of GLP-1. This ligand might be a promising new way of stimulating endogenous GLP-1 secretion using an oral regime. Further studies defining doses, formulation and long-term effects are needed.

879

Insulin sensitizer, BGP-15 prevents saturated fatty acid induced mitochondrial dysfunction

A. Kolonics[1], C. Magyar[2], E. Kiss[3], Z. Literati-Nagy[1], L. László[4], P. Literati-Nagy[1], K. Tory[1];
[1]Molecular Pharmacology, N-Gene Research Laboratories, [2]Institute of Enzymology, Biological Research Center, [3]Immunology, Eötvös Loránd University, [4]General Zoology, Eötvös Loránd University, Budapest, Hungary.

Background and aims: Mitochondrial rotenone-sensitive NADH:ubiquinone oxidoreductase (complex I) activity and substrate switching were found to be diminished in obese and type 2 diabetic patients. Saturated long chain fatty acids, like palmitate inhibit complex I activity and result in increased mitochondrial ROS production. BGP-15 (R,S-O-(3-piperidino-2-hydroxy-1-propyl)-nicotinic-acid-amidoxime) is a new type insulin sensitizer drug candidate in human phase 2 developmental stage. It has been demonstrated that BGP-15 facilitates the expression of inducible heat shock protein resulting in decreased activation of JNK, which is a common mediator of obesity associated insulin resistance. Affinity binding assay revealed binding of BGP-15 to NDUFS1, a 75 kDa iron-sulfure protein subunit of mitochondrial complex I. Now we report the effect of BGP-15 treatment on the activity of complex I and II and ROS production in palmitate and hyperglycemia exposed cells. We also aimed to characterize the possible docking site of BGP-15 at NDUFS1.
Materials and methods: The effects of BGP-15 on the activity of complex I and II was evaluated in human HaCaT keratinocytes and L6 murine myocytes using a specific electron acceptor, DCIP and NADH or succinate electron donor. ROS production was measured by MitoSox or Amplex Red fluorescent probes. Vina and Surflex programs were used for molecular docking.
Results: BGP-15 treatment resulted in a rapid increase in the activity of complex I while the activity of complex II was inhibited in hyperglycemia exposed cells. The elevated activity of complex I was maintained in the presence of the drug for days in hyperglycemic culture conditions. Palmitate treatment decreased the activity of complex I and increased the activity of complex II, and elevated mitochondrial ROS production in L6 myocytes. BGP-15 treatment restored the activity of complex I and reduced the activity of complex II. In addition super-oxide production was lowered back to the level of untreated control. Molecular docking analysis on the bacterial (Thermus Thermophylus) homologue of human NDUFS1 identified a specific binding site (DG = - 7.2 kcal/mol) for BGP-15.
Conclusion: Data indicate that BGP-15 ameliorates the effects of palmitate on complex I resulting in balanced substrate oxidation and reduced ROS production. Molecular docking results support the concept that BGP-15 may target complex I, the main substrate entry and ROS producing site of mitochondria. Prevention of saturated fatty acid induced mitochondrial dysfunction can significantly contribute to insulin sensitizing effect of BGP-15.

GFT505, a new PPARα/δ agonist improves lipid and glucose homeostasis in prediabetic patients with atherogenic dyslipidaemia and/or impaired fasting glucose

R. Hanf[1], E. Bruckert[2], B. Cariou[3], R. Darteil[1], D. Hum[1], B. Staels[4];
[1]GENFIT, Loos, [2]Hopital de la Salpetrière, Paris, [3]CHU Nantes, [4]UMR 1011, Institut Pasteur de Lille, France.

GFT505 is a drug candidate for the treatment of metabolic disorders associated with metabolic syndrome and Type 2 diabetes. GFT505 and GFT1007, its main active circulating metabolite, activate the PPARα and PPARδ subtypes. GFT505 potently reduces plasma triglycerides and total cholesterol and increases HDL cholesterol in animal models of dyslipidemia. GFT505 prevents the development of atherosclerotic plaques and has insulin-sensitizing properties in mice. In Phase I trials in healthy volunteers, GFT505 was well tolerated with no clinically relevant emergent adverse event. The maximum tolerated dose in humans has not been reached while a reduction in plasma triglycerides and increase in HDL-C was observed at doses from 40 to 100 mg/d. The safety of GFT505 was confirmed in the ensuing phase IIa trials. In a double blind, placebo controlled phase IIa trial conducted in 98 patients with atherogenic dyslipidemia (high triglycerides, low HDL-C), treatment with GFT505 at 80 mg/day for 28 days led to a 21 % (p=0.0027 vs placebo) reduction in triglycerides and a 9 % (p=0.003 vs placebo) increase in HDL-C. GFT505 significantly reduced ApoCIII (-17 %, p=0.04) and ApoB (-7 %, p=0.02), increased ApoA1 (+6%, p=0.002) and ApoA2 (+15 %, p<0.0001) and reduced fibrinogen and haptoglobin. These effects are comparable to those reported with fibrates, such as fenofibrate, in this population. In contrast, GFT505 did not induce clinically significant effects on homocysteine and creatinine. Finally, GFT505 reduced two distinct indicators of liver dysfunction: alanine aministransferase (ALAT, -15 % vs placebo, p=0.02) and Gamma Glutamyl Transpeptidase (-20 % vs placebo) while it did not affect plasma levels of aspartate aminotransferase. In a phase II clinical trial conducted in 47 patients with impaired fasting plasma glucose, impaired glucose tolerance and abdominal obesity, treatment with GFT505 (80mg/day) for 28-days led to a significant reduction in fasting plasma glucose levels (-5% vs placebo, p=0,03). In parallel, significant reductions in fasting plasma insulin (-25% vs placebo, p=0,009) and C-peptide (-11% vs placebo, p=0,03) were also obtained. Thus, the HOMA insulin-resistance index (HOMA-IR) was significantly reduced by -31% vs placebo (p=0,0027). Moreover, a beneficial effect of the compound on plasma lipids was observed with a significant reduction of LDL-C (-11% vs placebo, p=0,0049) and triglycerides (-25% vs placebo, p=0,0003) and an increase in HDL-C (+9% vs placebo, p=0,003). Finally, treatment with GFT505 led to a significant reduction in markers of inflammation (fibrinogen, -10%, p=0,0128; haptoglobin, -16%, p=0,007) while homocysteine levels remained unchanged. These first clinical trials position GFT505 as a new efficient and safe drug candidate for the treatment of prediabetic patients with impaired fasting glucose and atherogenic dyslipidemia.

881

P1738, a novel insulin sensitizer improves metabolic control with a favourable weight profile in mice

R.A. Marita, G.S. Raza, R. Rathish, S. Bhumra, J. Anthony, V. Bhor, G. Chimote, N. Deka, S. Sharma;
Piramal Life Sciences Limited, Mumbai, India.

Background and aims: Type 2 Diabetes is characterized by peripheral insulin resistance and insulin deficiency. While most of the current treatments have focused on improving glycemic control, measures that can prevent co-morbidities such as dyslipidemia, hypertension and obesity are useful in reducing cardiovascular disease. Thiazolidinedione (TZD) drugs, including rosiglitazone exhibit potent antidiabetic and insulin sensitizing effects. However, TZD therapy has been associated with adverse cardiovascular outcomes and weight gain. Therefore, insulin sensitizers with improved safety profile are urgently needed. In this regard, we have used a phenotypic screening paradigm, capable of selecting modulators of insulin sensitivity, and identified P1738 as the lead compound. The present study describes the *in vitro* and *in vivo* pharmacology of P1738.
Materials and methods: We screened our chemical library in the phenotypic assay of adipogenesis using 3T3-L1 cells. The positives were evaluated for glucose uptake in the insulin resistant adipocytes and were identified as hits. The antidiabetic efficacy of these hits was investigated in *ob/ob* and *db/db* mice. Further, cardiac and developmental toxicity was determined using the zebra fish model.
Results: P1738 (20 μg/ml) enhanced insulin-induced adipogenesis of 3T3 fibroblasts. P1738 stimulated glucose uptake (EC50 - 0.5 μM) in the insulin resistant adipocytes. P1738 did not cause activation of $PPAR_{\alpha/\gamma}$ receptors in transactivation assays. Chronic oral treatment of *ob/ob* mice with P1738 induced a dose-related reduction in plasma glucose (23% at 200 mg/kg) and triglyceride levels (18% at 100 mg/kg and above). An oral glucose tolerance test carried out on day18 revealed that P1738 improved ($p<0.01$) glucose tolerance similar to rosiglitazone. Interestingly, P1738 treatment did not induce weight gain in mice, at all the tested doses (50 to 200 mg/kg) compared to rosiglitazone treatment (5 mg/kg) which induced 12% gain ($p<0.001$). Further, P1738 treatment did not significantly affect hematocrit and plasma protein levels, in contrast to rosiglitazone which induced significant reduction ($p<0.001$). P1738 exhibited an excellent liver safety profile with no changes in weight or triglyceride levels, even at 200 mg/kg while rosiglitazone (5 mg/kg) caused hepatomegaly and 30% ($p<0.01$) increase in liver triglyceride levels. P1738 was also efficacious in *db/db* mice wherein administration of 100 mg/kg resulted in 26% reduction in glucose levels while rosiglitazone (5 mg/kg) induced 35% reduction. Importantly, while rosiglitazone caused significant ($p<0.05$) weight gain, animals exposed to P1738 did not register significant change in body weight. When administered to diet-induced obese mice, P1738 did not cause weight gain while rosiglitazone induced significant increase during the same period. In a zebrafish model, P1738 (100 μg/ml) did not induce any adverse effects whereas pericardial edema was observed with rosiglitazone (25 μg/ml).
Conclusion: This study shows that P1738 is a novel insulin sensitizer with no $PPAR_{\alpha/\gamma}$ transactivation potential. Improvement in glycemic and extraglycemic parameters caused by P1738, in mouse models of obesity, is associated with a favorable weight profile. Thus P1738, with its unique pharmacology and improved safety profile, may represent an alternative treatment for Type 2 Diabetes.

882

A selective GPR40 agonist, TAK-875, stimulates glucose-dependent insulin secretion without beta cell toxicity and decreases blood glycosylated haemoglobin levels in diabetic rats

K. Takeuchi, Y. Tsujihata, R. Ito, M. Suzuki, A. Harada, M. Hazama;
Pharmaceutical Research Division, Takeda Pharmaceutical Company Limited, Osaka, Japan.

Background and aims: GPR40 is highly and dominantly expressed in pancreatic beta cells and is activated by medium- to long-chain free fatty acids (FFAs) to potentiate glucose stimulated insulin secretion. While GPR40 is an attractive target for Type 2 diabetes, it is unclear whether agonists or antagonists represent the best therapeutic approach. TAK-875 is a novel, oral, and selective small molecule agonist of GPR40 under development as a once-daily treatment for type 2 diabetes. In this study, pharmacological effects of TAK-875 were examined.
Materials and methods: EC_{50} for inositol monophosphate (IP) production was assessed in Chinese hamster ovary cells expressing human GPR40 (hGPR40-CHO). Acute effects (2h) of TAK-875 and glibenclamide were measured in rat insulinoma INS-1 833/15 cells. Chronic effects (72h) of TAK-875 and FFAs were measured in rat insulinoma INS-1 832/13 cells. Oral glucose tolerance test (OGTT) was performed in male N-STZ-1.5 diabetic rats (18w). Measurement of metabolic parameters after chronic treatment with TAK-875 for 6 weeks were performed in female Wistar fatty (WF) rats (14w).
Results: TAK-875 (EC_{50}=0.072 μM) showed over 400-fold stronger agonist activity compared to oleic acid (EC_{50}=29.9 μM) in IP production assay in hGPR40-CHO cells. In rat insulinoma INS-1 833/15 cells, TAK-875 increased intracellular IP and calcium concentration, indicating that the compound activates Gαq signaling pathway. Unlike the sulfonylurea glibenclamide (10 μM), the insulinotropic action by TAK-875 (10 μM) in INS-1 833/15 was glucose-dependent. Chronic exposure to TAK-875 (100 μM) for 72h in INS-1 832/13 cells did not affect insulin secretion, insulin content, or caspase 3/7 activity, while similar exposure to palmitic acid (1 mM) decreased both insulin secretion and insulin content, and increased caspase 3/7 activity. In an oral glucose tolerance test in N-STZ-1.5 diabetic rats, TAK-875 showed dose dependent improvement of glucose tolerance and potently augmented insulin secretion. Chronic treatment with TAK-875 in WF rats dose dependently decreased glycosylaed hemoglobin with no effects on body weight or pancreatic insulin content.
Conclusion: Our results support the concept that TAK-875 therapy may be an effective treatment of Type 2 diabetes without causing beta-cell toxicity.

883

Chemokine receptor 2 antagonist CCX140-B in Phase 2 for type 2 diabetes

T. Sullivan, S. Miao, R. Berahovich, N. Zhao, S. Ungashe, D. Johnson, P. Bekker, J. Jaen, T.J. Schall;
ChemoCentryx, Inc, Mountain View, USA.

Background and aims: CCX140-B is a highly specific oral chemokine receptor 2 (CCR2) antagonist in Phase 2 development for treatment of type 2 diabetes mellitus. Increased adiposity leads to elevated recruitment of inflammatory monocytes/macrophages into adipose tissue. Concurrent with increased adipose macrophage numbers, local and systemic elevations in inflammatory markers, such as TNFα, IL-6, and monocyte chemoattractant protein-1 (MCP-1)/chemokine ligand 2 (CCL2) are also seen and these inflammatory mediators have been shown to impair insulin sensitivity in multiple tissues. Studies in rodent models of insulin resistance and type 2 diabetes have indicated that the CCR2:MCP-1 axis is a primary control point for the entry of inflammatory macrophages in the adipose tissue of obese subjects.
Materials and methods: Male C57Bl/6 mice were placed on high-fat diet at 6 weeks of age for 18 to 24 weeks. Metabolic profiling (blood glucose, insulin, adiponectin) was determined in fasted mice. CCR2 antagonist or placebo was delivered once daily via subcutaneous injection for 7 to 28 days. Adipose tissue macrophage numbers were determined by fractionation of epididymal fat pads followed by flow cytometry to identify macrophages. Preclinical studies were followed by single and multiple ascending dose placebo-controlled Phase 1 clinical trials of the CCR2 antagonist CCX140-B at doses ranging from 0.05 mg to 10 mg in 88 healthy volunteers.
Results: Daily treatment with CCR2 antagonist significantly improved fasting glucose and HOMA-IR levels in obese, diabetic mice over 28 days of treatment (see table). Circulating adiponectin levels were significantly reduced in obese, diabetic mice and this was reversed by CCR2 antagonist treatment. The metabolic improvements correlated with a significant reduction in adipose tissue macrophage numbers. CCL2 levels were unchanged in mice treated with CCR2 antagonist. Additionally, circulating populations of monocytes were unchanged in the mice. CCX140-B was well tolerated in Phase 1 clinical trials. No serious adverse events (AEs) or withdrawals due to AEs were observed. No clinically significant laboratory abnormalities, vital signs, or ECG changes were observed. CCX140 pharmacokinetics were relatively linear across the dose range, with T_{max} of 1.4 to 3.2 hr and plasma half life of 40 to 58 hrs. Plasma MCP-1 levels, as well as circulating monocyte populations were unchanged after CCX140-B dosing, in contrast to results observed with other CCR2 antagonists. Based on the encouraging results from preclinical and Phase 1 clinical trials, a Phase 2 study in subjects with type 2 diabetes mellitus was initiated.
Conclusion: Oral CCR2 antagonist treatment improved metabolic function in mice without a corresponding increase in MCP-1. CCX140-B was well tol-

erated in Phase 1 with an attractive PK profile suitable for 5 to 10 mg once daily oral treatment.

CCR2 Antagonist Effect on Metabolic Profile in C57Bl/6 Mice (mean ± SD)

Variable	Normal Lean Mice	Vehicle-Treated Obese Mice	CCR2 Antagonist Treated Obese Mice
Fasting Blood Glucose (mg/dL)	105 ± 5	205 ± 9	140 ± 9*
Serum Adiponectin (ng/mL)	18.0 ±1.1	8.0 ± 0.5	14.3 ± 0.5*
HOMA-IR	1.7 ± 0.5	39.5 ± 9.0	9.4 ± 1.7*
Adipose Macrophages (cells/g)	34000 ± 9300	65000 ± 8500	27000 ± 6500*

Imeglimin, a novel glimin oral antidiabetic, exhibits good glycaemic control in type 2 diabetes mellitus patients

V. Pirags[1], H. Lebovitz[2], P. Fouqueray[3];
[1]Faculty of Medicine, Pauls Stradins Clinical University Hospital, Riga, Latvia, [2]Department of Medicine, State University of New York, Staten Island, USA, [3]Poxel Pharma, Lyon, France.

Background and aims: Imeglimin is the first in the new glimin class of oral antidiabetic agents that targets insulin resistant organs and addresses beta cell failure. In decreasing mitochondrial oxidation, imeglimin inhibits excessive hepatic glucose production and restores peripheral glucose uptake as well as glucose-dependent insulin secretion. We investigated imeglimin's effects on glycaemic control compared with metformin in T2D patients.
Material and methods: Two phase II studies were conducted. In one, a 4-week repeat dose of imeglimin (2000 mg once daily [od], N=20; 1000 mg twice daily [bid] N=19) was compared with metformin (850 mg bid, N=19) over 4 weeks on glucose AUC during an OGTT. In the other, two daily doses of imeglimin (500 mg bid, N=31; 1500 mg bid, N=31) were compared with placebo (N=33) and metformin (850 mg bid, N=33) over 8 weeks and AUC glucose during a prolonged meal test, fasting plasma glucose (FPG) and HbA_{1c} were recorded.
Results: Baseline-adjusted changes in the OGTT AUC were -33% for imeglimin bid ($p<0.0001$), -30% for metformin ($p<0.0004$) and -10% for imeglimin od ($p=0.0305$). In the second study, the least square mean changes in $AUC_{0\text{-}6h}$ were significantly different from placebo for imeglimin 1500 mg and metformin with no statistical difference between the two treatment groups. Decreases in FPG and HbA_{1c} were observed for imeglimin 1500 mg and metformin. Only limited efficacy of the imeglimin 500 mg dose was noted. A greater response in all glycaemic parameters was generally observed for treatment naïve subjects compared with those previously treated and those with more severe hyperglycemia (HbA_{1c} ≥8%) compared with less severe hyperglycemia (HbA_{1c} <8%).

	Mean Change from Baseline (Standard Error of the Mean)							
Parameter	**Imeglimin 500 mg bid**		**Imeglimin 1500 mg bid**		**Metformin 850 mg bid**		**Placebo**	
$AUC_{0\text{-}6h}$ glucose (mmol/L)								
Overall	103.4	(158.5)	-365.7	(179.5)	-629.4	(144.7)	463.1	(165.1)
p-value	0.086		0.003		<0.0001		--	
Treatment naïve	-58.1	(153.8)	-515.9	(349.5)	-672.3	(191.1)	855.7	(159.1)
FPG (mmol/L)								
Overall	0.24	(0.35)	-0.88	(0.29)	-1.39	(0.21)	0.75	(0.35)
Treatment naïve	-0.15	(0.07)	-1.13	(0.29)	-1.63	(0.19)	1.21	(0.22)
HbA_{1c} (%)								
Overall	0.37	(0.18)	-0.13	(0.11)	-0.26	(0.09)	0.29	(0.12)
Treatment naïve	-0.40	(0.08)	-0.54	(0.07)	-0.44	(0.14)	0.11	(0.1)

No serious or severe adverse events associated with imeglimin were reported. No imeglimin-related adverse events were noted at its highest dose. In addition, no clinically significant changes in laboratory parameters, vital signs or ECGs were observed.
Conclusions: It was demonstrated that imeglimin was as effective as metformin at reducing $AUC_{0\text{-}6h}$, FPG and $HbA_{1c,}$ with no safety issues. Imeglimin is suitable for use as monotherapy at diagnosis of T2D and may be effective at any stage in the T2D continuum, from diagnosis through to disease complications. Because of its unique mechanism of action it may be well suited for combination therapy with most other classes of antidiabetic agents.

A multicenter, randomised, placebo-controlled, paralled group, double-blind, Phase II trial to evaluate the efficacy and safety and to determine the optimal dose of LC15-0444 in Korean subjects with type 2 diabetes

S.W. Kim[1], W.Y. Lee[1], K.-H. Yoon[2], S.J. Yoo[3], I.-K. Lee[4], S.H. Baek[5], Y.K. Kim[6], M.K. Lee[7], K.S. Park[8], J.Y. Park[9], B.S. Cha[10], H.W. Lee[11], K.W. Min[12], H.-Y. Bae[13], E.J. Rhee[1];
[1]Department of Internal Medicine, Kangbuk Samsung Hospital, Seoul, [2]Seoul St. Mary's Hospital, [3]Holy Family Hospital, Bucheon, [4]Kyungpook National University Hospital, Daegu, [5]Korea University Guro Hospital, Seoul, [6]Pusan National University Hospital, [7]Samsung Medical Center, Seoul, [8]Seoul National University Hospital, [9]Asan Medical Center, Seoul, [10]Severance Hospital, Seoul, Korea, Republic of, [11]Yeungnam University Medical Center, Daegu, [12]Eulji Medical Center Medical Corporation, Seoul, [13]Chosun University Hospital, Gwangjoo, Republic of Korea.

Background and aims: The objective of this study was to evaluate the efficacy and the safety of a novel dipeptidyl peptidase-4 (DPP-4) inhibitor, LC15-0444 and determine the optimal dose in Korean subjects with exercise/diet-controlled type 2 diabetes mellitus.
Materials and methods: In a double-blind, randomized, multicenter, parallel group, dose-range finding study, 145 patients (91 men and 54 women) with median age 53 years and with median BMI 25.1 kg/m^2 participated the study. Median fasting plasma glucose at baseline was 145 mg/dL and median HbA1c was 7.9%. Median duration since diagnosis of diabetes was 3 years. After 2 weeks of exercise/diet program and 2 weeks of placebo period after that, subjects were randomized to one of 4 groups, placebo, 50, 100 and 200 mg, for 12-week active treatment period.
Results: All three doses of LC15-0444 reduced HbA1C level from baseline to week 12 significantly compared to placebo (-0.06 vs. -0.98, -0.74, -0.78% in placebo, 50,100 and 200 mg respectively), with no significant differences among different dosings. Subjects with higher HbA1c level(≥8.5 %) at baseline experienced greater HbA1c reductions compared with the subjects with lower HbA1c level(<8.5%). Insulin secretory function assessed by HOMA-β, and C-peptide, and insulinogenic index was significantly improved by LC15-0444 treatment, and insulin sensitivity, assessed by HOMA-IR, was also significantly improved after 12 weeks of treatment. For lipid parameters, 50 and 200 mg groups showed significantly reduced total cholesterol and LDL-C level at week 12 from baseline compared with placebo. All 3 dosing groups did not have any effects on body weight nor on waist circumference, and the incidence of adverse events was similar in all four groups.
Conclusion: Once-daily LC15-0444 monotherapy for 12 weeks improved glycemic control in HbA1c, FPG, post oral glucose tolerance test (OGTT) glucose, improved measures of β-cell function and insulin sensitivity, and was well tolerated in Korean subjects with type 2 diabetes.

The new dual glucagon-GLP-1 agonist ZP2929 improves glycaemic control and reduces body weight in murine models of obesity and insulin resistance

J.R. Daugaard[1], D. Riber[1], K.S. Larsen[1], E. Maier[1], C.Æ. Bæk[1], G. Kampen[2];
[1]Zealand Pharma A/S, Glostrup, [2]Novo Nordisk A/S, Bagsværd, Denmark.

Background and aims: Oxyntomodulin is released from L cells of the small intestine in response to meal ingestion, and is believed to exert its biological effects by activating both the GLP-1 receptor and the glucagon receptor, i.e. by acting as a dual glucagon-GLP-1 agonist. ZP2929 is a potent dual glucagon-GLP-1 receptor agonist with a pharmacokinetic profile compatible with once daily dosing. The effect of ZP2929 was studied in eight months high fat fed C57Bl/6J mice, as an animal model of insulin resistance and in four weeks high fat fed C57Bl/6J mice, as a model of obesity. ZP2929 was compared to vehicle and exendin-4.
Materials and methods: To assess the effect of ZP2929 on insulin resistance, eight months high fat fed C57Bl/6J male mice were randomized into groups with similar average fasting glucose, and treated twice daily s.c. with ZP2929 (10 nmol/kg), exendin-4 (10 nmol/kg), or vehicle. After 3 weeks of treatment,

following an initial blood sample for the determination of fasting blood glucose level, oral glucose tolerance tests were performed. To investigate the effect of ZP2929 on body weight gain, four weeks high fat fed C57Bl/6J male mice were randomized into groups with similar average body weight and treated twice daily s.c. with ZP2929 (0.6, 1.6, 3.2, 6.4 and 12.7 nmol/kg), exendin-4 (0.2, 0.5, 2, 5, 10 and 20 nmol/kg) or vehicle. Before treatment and after four and six weeks of treatment, blood samples were taken and blood lipids (low and high density lipoproteins (LDL and HDL), total cholesterol (TC) and triglycerides) measured.
Results: In eight months high fat fed C57Bl/6J mice, treatment with ZP2929 and exendin-4 for three weeks significantly ($p<0.05$) prevented the increase in fasting blood glucose seen in vehicle-treated animals. ZP2929 and exendin-4 improved glucose tolerance (measured as decrease in the area under the glucose curve) by 15.7 % and 30.3 %, respectively. In four weeks high fat fed C57Bl/6J mice, treatment with ZP2929 and exendin-4 significantly ($p<0.05$) and dose-dependently reduced body weight gain over time, compared to vehicle-treated animals. ZP2929 (12.7 nmol/kg) was significantly ($p<0.05$) more efficient than a similar dose of exendin-4 (10 nmol/kg) in preventing body weight gain. Plasma lipid parameters demonstrated a tendency to increase over time in vehicle-treated animals. At the two highest doses, ZP2929 and exendin-4 reduced the increase in plasma LDL, HDL and TC.
Conclusion: In conclusion, the new glucagon-GLP-1 agonist ZP2929 improves glucose control, markedly decreases body weight gain and improves blood lipid profile in murine models of insulin resistance and obesity.

887

Long-term effect of amylin on the glucose metabolism of extrapancreatic tissues in insulin-resistant and type 2 diabetic states

A. Acitores[1], P. Moreno[1], I. Gutiérrez-Rojas[1], B. Nuche-Berenguer[1], M. El Assar[2], L. Rodrigrez-Mañas[2], I. Valverde[1], A. Novials[3], M.L. Villanueva-Peñacarrillo[1];
[1]IIS-Fundación Jiménez Díaz, Madrid, [2]Hospital de Getafe, Madrid, [3]Hospital Clinic, Barcelona, Spain.

Background and aims: Amylin is glucose dependently co-secreted with insulin from the pancreatic β-cell, one another perhaps in an independent manner; it inhibits gastric emptying and glucagon release, reduces postprandial hepatic glucose productions, and shows anorexic effects. In type 2 diabetes, amylin secretion could is impaired. We studied the effect of amylin treatment on parameters related to the glucose metabolism of extrapancreatic tissues, in insulin-resistant (IR) and type 2 diabetic (T2D) rat models, compared to normal (N) animals.
Materials and methods: Male Wistar rats were used. IR was induced by chronic feeding -8 weeks- with standard chow combined with D-fructose (20% in the drinking water). T2D was developed by streptozotocin injection (100 μg/g bw) at birth. IR, T2D and N were treated (3 days) with saline (control) or 100 pM amylin (n=5-10 rats/group), through an osmotic pump; in fed conditions, blood samples were taken before and by the end of treatment for plasma glucose and insulin (RIA) measurements; GLUT-2 and GLUT-4 expression -Western blot and RT-PCR- was respectively studied in liver, muscle and fat; liver glycogen content, *soleus* muscle glycogen synthase *a* (GS*a*) -UDP-[^{14}C]glucose incorporation into glycogen- and isolated adipocytes glucose transport (GT) -2-deoxi-D-[1,2-^{3}H]glucose uptake-, were measured.
Results: The liver of IR (n=7 rats) and T2D (n=5), both showed GLUT-2-mRNA lower than (0.23±0.03 and 0.16±0.1 times N-control; $p<0.001$) and protein (overall mean: 62±6% N-control, $p<0.001$); amylin further reduced ($p<0.01$) mRNA in IR, without altering that in T2D; while failing to modify GLUT-2-protein in either group, amylin increased it in N (182±15% N-control, $p<0.001$). Respect N, liver glycogen content in IR (193±20 μg/mg protein) and T2D (230±18 μg/mg protein) was close to half lower ($p<0.01$); amylin increased the value in IR and T2D (573±66 μg/mg protein and 398±4, $p<0.01$ *vs* respective control). Muscle Glut-4-mRNA (n=10 rats) in IR and T2D were higher and lower, respectively, than in N (both $p<0.01$); amylin failed to modify the level in N or T2D, but apparently increased it in IR (1.49±0.39 times IR-control); Glut-4-protein was higher in IR (243±39% N-control $p<0.05$) and slightly lower in T2D ($p<0.05$); amylin, further reduced it in T2D (72±4% T2D-control, $p<0.001$) while increased it in IR (157±15% IR-control, $p<0.05$). GS*a* in IR and T2D was lower (38±14% N and 40±13%, respectively; $p<0.05$), and amylin normalized it in IR (53±3% N). In adipose tissue (n=11 rats), GLUT-4-mRNA in IR and T2D was lower (both $p<0.02$ *vs* N), while the protein was higher in T2D ($p<0.001$ *vs* N); amylin reduced GLUT-4-protein in N, but increased it in IR and T2D ($p<0.01$). GT in IR (8.1±0.5 fmol/10^5 cells, n=6) was lower ($p<0.01$ *vs* N) and that in T2D (45.1±2.7, n=23) higher ($p<0.001$); amylin normalized it in both groups, by respectively increasing ($p<0.02$) and reducing ($p<0.001$) the value. No major changes in plasma parameters were detected in any group after treatment.
Conclusion: In insulin-resistant and type 2 diabetic states, amylin could exert a restoring action on the deleterious glucose metabolism of extrapancreatic tissues participating in the glucose homeostasis, by perhaps increasing insulin sensitivity through its normalizing effect upon their altered glucotransporters expression.

Vitamin D and calcium supplementation in adults at risk for type 2 diabetes. The CADDM randomised controlled trial

A. Pittas[1], J. Goetz[1], B. Dawson-Hughes[2];
[1]Tufts Medical Center, Boston, [2]Tufts University, Boston, USA.

Background and aims: Vitamin D and calcium have been shown to modify risk of type 2 diabetes in observational studies, but evidence from trials is lacking. The aim of the study was to determine whether vitamin D or calcium supplementation either alone or in combination improve glucose homeostasis in adults with glucose intolerance.
Materials and methods: Ninety-two adults with fasting plasma glucose (FPG) ≥100 mg/dl or 2-hour glucose (2hPG) ≥140 mg/dl after 75 grams of dextrose and Hemoglobin A1c 5.8 - 7% were randomized in a 2x2 factorial design to 1 of 4 arms as follows: vitamin D3 (2,000 IU once daily) and calcium carbonate (400 mg twice daily), vitamin D3 and placebo-calcium, calcium and placebo-vitamin D or placebo-vitamin D and placebo-calcium between October 2007 and November 2009. Outcome was change in glycemia (hemoglobin A1c, FPG and 2hPG) from baseline to 16 weeks. [ClinicalTrials.gov Identifier: NCT00436475]
Results: Enrolled participants had a mean age of 57 years, BMI of 32 kg/m2, 25-hydroxyvitamin D of 32 ng/ml and A1c of 5.9%. The difference in 25-hydroxyvitamin D between vitamin D3 and placebo-vitamin D was 13.3 ng/ml (p<0.001). Participants assigned to vitamin D3 had a smaller rise in hemoglobin A1c compared to those on placebo-vitamin D (0.05 vs. 0.15% respectively; p=0.034). Fasting plasma glucose (-0.08 vs. 2.2 mg/dl; p=0.12) and 2hrPG (-10.1 vs. 0.54 mg/dl; p=0.14) also improved, but the difference between groups was not statistically significant. Combined vitamin D3 and calcium carbonate improved glycemia more than vitamin D3 alone or calcium alone compared to the group assigned to placebos (0.04 vs. 0.08 vs. 0.11 vs. 0.20% respectively).
Conclusion: In adults at risk for type 2 diabetes, supplementation with vitamin D3 attenuates the increase in glycemia that occurs over time. The addition of calcium carbonate appears to further improve glycemia. Our findings need to be confirmed in long-term randomized trials.

The effect of vitamin D supplementation on beta cell function and insulin sensitivity during a mixed meal tolerance test in healthy humans

G. Bock[1], B. Prietl[1], J.K. Mader[1], J. Fruhmann[1], S. Pilz[1], N. Hueter[1], B.M. Obermayer-Pietsch[1], T.R. Pieber[1,2];
[1]Endocrinology and Nuclear Medicine, University Hospital Graz, [2]Joaneum Research, Graz, Austria.

Background and aims: Increasing evidence from animal and human studies suggests that vitamin D may play a role in modifying risks of diabetes and other autoimmune diseases. Potential mechanisms of action of vitamin D on glucose metabolism include direct effects on the beta cell function and insulin sensitivity. The aim of our study was to evaluate the effect of a short time, high dose 25-OH vitamin D [25(OH)D] supplementation on glucose metabolism in healthy humans.
Materials and methods: 35 healthy subjects (16 females / 19 males, 35±11.4 years, 24.1±3.8 kg/m² BMI) were randomised to vitamin D supplementation (140.000IU monthly) or placebo (almond oil). A standard liquid mixed meal tolerance test (MMTT) (6ml Isosource /KG bodyweight) was performed at baseline and after 3 months of treatment. Areas under the curve (AUC) for glucose, insulin and C-peptide from pre-meal to 120min after consumption were calculated as were the Matsuda index of insulin sensitivity.
Results: 25(OH) D serum levels increased from 27.2±11.0 (mean ±SD) to 60.2±21.1ng/ml in the treatment group (n= 17) whereas 25(OH) D levels decreased from 25.6±7.1 to 18.8±7.2 ng/ml in the placebo group (n=18) during the 12 week study period. In the group receiving 25(OH) D supplementation the AUC for glucose (12258.2±1760.6 vs. 11577.8±2024.1 mg/dl; p=0.020) and insulin (5656±3207 vs. 4935.5±3363 µU/ml; p=0.087) decreased, with the main improvement of the AUC delta glucose (43.5±23.0 vs. 25.6±15.8mg/dl; p=0.014) and AUC delta insulin (83.4±56.5 vs. 59.9±50.8µU/ml; p=0.003) from 0 to 30min of the MMTT. Changes in AUC for C-peptide did not reach significant levels. The Matsuda insulin sensitivity index values increased slightly from 11.1±5.3 to 12.6±9.5 (p n.s.) in the treatment group but decreased significantly in the placebo group from 15.1±13.3 to 10.4±5.9 (p=0.023). In both groups no clinically relevant adverse events occurred.
Conclusion: Our data show that vitamin D supplementation in apparently healthy humans with insufficient 25(OH)D levels improves beta cell function and insulin sensitivity over a short period of time and support the beneficial effects of vitamin D on glucose metabolism.

Anti-diabetic effect of add-on gynostemma pentaphyllum tea therapy with sulfonylureas in randomly assigned type 2 diabetic patients

H.T.T. Vu[1,2], P.V. Dao[3], T. Pham[4], H.K. Nguyen[5], C.-G. Ostenson[1];
[1]Department of Molecular Medicine & Surgery, Endocrine & Diabetes Unit, Karolinska Institute, Stockholm, Sweden, [2]Department of Internal Medicine, Hanoi Medical University, Viet Nam, [3]Department of Pharmacology, Hanoi Medical University, Viet Nam, [4]National Institute of Gerontology, Hanoi, Viet Nam, [5]Dept of Internal Medicine, University of Manitoba, Winnipeg, Canada.

Background and aims: In Vietnam, herbs have been used traditionally to treat diabetic patients. Our previous works on *Gynostemma pentaphyllum* (GP) have revealed the anti-diabetic effect of GP extract in normal rats, associated with a novel insulin releasing gypenoside - phanoside. In addition GP tea has been proven in our recent clinical study to possess anti-diabetic effect with good safety data in newly diagnosed T2D patients, and to have effect on insulin sensitivity. The aim of the study was to investigate the anti-diabetic effect of the traditional Vietnamese herb GP as add-on therapy with sulfonylurea (SU) in 25 drug-naïve type 2 diabetic (T2D) patients.
Materials and methods: After 4-week treatment with gliclazide modified-release preparation, 30 mg daily, all patients were randomly assigned into 2 groups to add-on GP tea or placebo tea, 6g daily, during eight weeks. Fasting plasma glucose (FPG), C-peptide and insulin levels, HbA_{1C} and oral glucose tolerance tests (OGTT) were measured before, during and after the treatment.
Results: After 4-week treatment with SU, FPG and HbA_{1C} significantly decreased (p<0.001), C-peptide and insulin levels increased, and lipid profile improved significantly. There were no statistically significant differences between the groups allotted to GP and placebo tea. The decrease in FPG after eight weeks was 2.9 ± 1.7 mmol/l in the GP group and 0.9 ± 0.6 mmol/l in the control group (p < 0.001). Therapy with GP tea also significantly decreased 30 and 120 minute OGTT post-load values. HbA_{1C} levels decreased approximately 2%-units in the GP group compared to 0.7%-unit in the controls (p=0.001). The glycometabolic improvements were achieved without any major change of circulating insulin and C-peptide levels. There were no changes in Homeostasis Model Assessment-Insulin Resistance, lipids, body measurements, blood pressure and no reported hypoglycemias, or acute adverse effects regarding kidney and liver parameters.
Conclusion: The results of this study show that GP tea in addition to SU could offer an advantage over the addition of other oral medication to treat type 2 diabetic patients.

Silibinin reverses insulin resistance in an animal model of high-fructose diet by an inhibition of glucose-6-phosphatase activity

C. Sánchez-Martín[1], M.N. Sanz[1], D. Detaille[2], O. Bourron[3], F. Foufelle[3], J.M. Recio-Córdova[4], F. Gómez-Peralta[5], G. R.-Villanueva[1], M.Y. El-Mir[1];
[1]Physiology and Pharmacology, University of Salamanca, Spain, [2]University of Grenoble-I, Grenoble, France, [3]Centre de Recherches des Cordeliers, Paris, France, [4]Endocrinology Unit, University Hospital of Salamanca, Spain, [5]Endocrinology and Nutritional Unit, Nuestra Señora de Sonsoles Hospital, Ávila, Spain.

Background and aims: High fructose diet causes insulin resistance (IR) and alterations in glucose metabolism in Wistar rats. The flavonoid silibinin (SB) has recently showed important properties to be used in the treatment of type

2 diabetes. Previous studies *in vitro* of our group have shown that SB inhibits hepatic gluconeogenesis in perifused rat hepatocytes by an inhibition of glucose-6-phosphatase enzyme. The aim of this study was to explore the capacity *in vivo* of silibinin to reverse the particular alterations to IR induced in high fructose-fed rats, as well as the underlying mechanisms.

Materials and methods: Male Wistar rats were divided into two batches. One batch received a standard diet, and the other received a fructose-enriched diet. After 4 weeks, each group of rats was divided into two groups. One group received SB (50 mg/kg/day, i.p.) for additional two weeks, while the other received SB vehicle. Hepatocytes were isolated from starved rats, perifused at 37ºC and titrated with increasing substrate concentrations of dihydroxyacetone (DHA). We measured glucose concentrations in cellular perifusate and dihydroxyacetone phosphate (DHAP), glucose-6-phosphate (G6P) and fructose-6-phosphate (F6P) in the cellular fraction. The effect *in vivo* of SB on glucose-6-phosphatase activity was also investigated.

Results: In perifused hepatocytes, fructose diet increased gluconeogenesis ($J_{Glucose}$) as compared with control by 25% (DHA 2.4 mM, p<0.001). Administration of SB normalized this metabolic alteration in fructose-fed rats (DHA 2.4 mM, p<0.001). Also, fructose-enriched diet increased DHAP, G6P and F6P concentrations at each steady state, giving a double relationship between $J_{Glucose}$ and DHAP, F6P and G6P. SB normalized this effect. On the other hand, high fructose diet increased glucose-6-phosphatase activity as compared with control by 10% (G6P 20 mM, p<0.05). SB fully reversed this effect. Regarding the kinetic parameters of glucose-6-phosphatase enzyme, fructose diet increased the maximal velocity (V_{max}; p<0.05) and decreased Michaelis-Menten constant (K_m; p<0.01). Administration of SB only reversed V_{max} (p<0.05) compared to fructose fed rats.

Conclusion: SB reverses metabolic alterations proper to insulin resistance in Wistar rats by an inhibition of glucose-6-phosphatase enzyme. These results suggest that SB could be beneficial as complementary therapy for the treatment of type 2 diabetes.

The natural flavonoid Resveratrol reduces hepatic gluconeogenesis and respiration by a direct and a non-gene modification manner

M.N. Sanz[1], C. Sànchez-Martin[1], D. Detaille[2], C. Pueyo[1], C. Ortega-la[1], O. Bourron[3], F. Foufelle[3], X. Leverve[2], M.Y. El-Mir[1];
[1]Physiology and Pharmacology, University of Salamanca, Spain, [2]Laboratoire de Bioénergétique Fondamentale et Appliquée, University of Grenoble I, INSERM U884, France, [3]Centre de Recherches des Cordeliers, INSERM, UMR-S 872, Paris, France.

Background and aims: Resveratrol is a polyphenolic flavonoid with potent antioxidant activity. It is present in a variety of plants, notably berry fruit, and has emerged as a promising chemotherapeutic molecule due to its health benefits, especially in cancer, type 2 diabetes, cardiovascular and neurological diseases. The diverse biological effects of resveratrol refer to its ability to target many intracellular molecules, mainly through the activation of sirtuins, a class of NAD^+-dependent deacetylases that affect multiple transcription factors and other protein targets.To investigate other possible mechanisms of action of Resveratrol without involvement of gene activation in the liver, the most important organ of insulin resistance in type 2 diabetes.

Material and methods: Hepatocytes were isolated from 24h starved rats according to the method of Berry and Friend. They were perifused at 37ºC with Krebs-bicarbonate-calcium satured with O_2/CO_2 at a flow rate of 5 ml/min. Saturating concentrations of dihydroxyacetone (DHA) (0; 0.15; 0.30; 0.60; 1.20; 2.40; 4.80 mM) were used as exogenous substrate, in the presence or absence of 10 μM Resveratrol, to get seven consecutive steady states. Glucose, pyruvate and lactate concentrations were measured in cell perifusate for each steady state. We also studied the direct effect of Resveratrol on oxygen consumption rate (JO_2) using mitochondria isolated by differential centrifugation from livers of fed Wistar rats. JO_2 was measured polarographically at 37° using a Clark-type oxygen electrode, with either glutamate/malate (GM) or succinate/ malate (SM) as energy substrates of complex I or II, respectively.

Results: In perifused hepatocytes, Resveratrol (10 μM) inhibited hepatic glucose output ($J_{glucose}$; p<0.01) by 28% and glycolysis (J_{L+P}), determined by the addition of lactate+pyruvate, by 22% (DHA 2.4 mM; p<0.005). According to these results, we obtained an inhibition of total DHA metabolic flux ($J_{2glucose+L+P}$) by 25% (p<0.005) and a decrease of cytosolic NADH/NAD^+ redox state, estimated as the lactate/pyruvate ratio, of nearly 25 % as well (p<0.005). Resveratrol did not significatively affect the state 4 of respiration whatever the respiratory substrates used. On the contrary, the flavonoid inhibited the phosphorylating state 3 (in presence of ADP) by 15% with either substrate.

Conclusion: Resveratrol, a potent antioxidant flavonoid, is recently investigated for its therapeutic and preventive potential in age-related diseases like type 2 diabetes. For the first time we demonstrate that this compound exerts direct effects upon hepatic metabolism, *i.e.* inhibitions of hepatic gluconeogenesis and cell respiration. This acute response could be beneficial for the treatment of such metabolic disorders.

A prescribed Chinese medicine improves glucose profile and ameliorates oxidative stress in GK rats fed with high fat diet

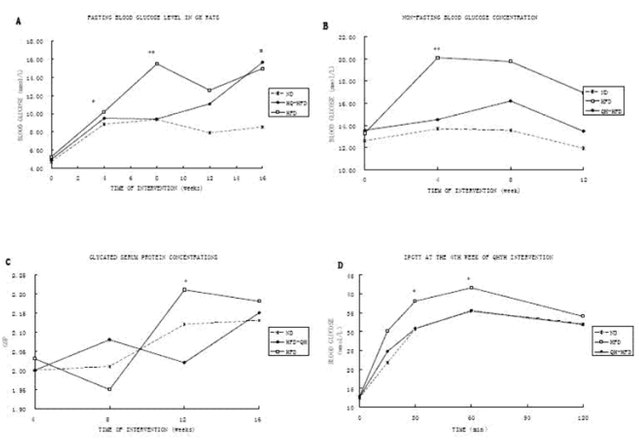
L. Wu[1], X. Gao[2];
[1]Geriatrics, [2]Endocrinology & Metabolism, Fudan University, Shanghai, China.

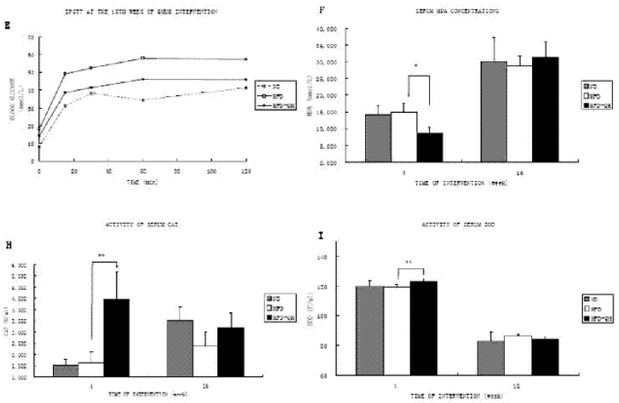
Background: The intrinsic anti-oxidative defence system of pancreatic β cells is fragile and oxidative stress is an underlying mechanism of β cell dysfunction. High-fat diet increases oxidative stress and exacerbates hyperglycemia in GK rat. We previously observed the prescribed traditional Chinese medicine preparation "Qing Huo Yi Hao" (QHYH) decreased urinary micro-albumin excretion in type 2 diabetic patients and also demonstrated its anti- oxidative activity by electron paramagnetic resonance. Recently we confirmed that QHYH protect endothelial cells from high glucose induced ROS production. So we hypothetized that QHYH might also protect β cell and improve glucose profile. We use GK rats fed with high-fat diet treated by QHYH to determine whether QHYH will improve glucose metabolism and ameliorate oxidative stress.

Materials and methods: 4-week-old male GK rats were given high fat diet (4.8kcal/g, 52% of the energy from fat) and divided randomly into 2 groups: QH group(n=10), rats were administered QHYH solution twice a day (3ml/Kg/d); and control (HFD) (n=10). Meanwhile, rats (ND) (n=10) fed normal chow (3.2kcal/g, 12% of the energy from fat)as normal control. Blood glucose and glycated serum protein(GSP) concentrations were measured every 4 week. IPGTT were done in 5 rats of each group at 4th and 16th week. Serum MDA concentration and activities of antioxidant enzymes were measured at the 4th and 16th week. Rats were sacrificed at the end of 16th week. Pancreas were taken out for morphological studies by immunohistochemistry to quantitatively determine β cell mass and relative volume. Nitrotyrosine and 8OHdG staining was also done.

Results: Of the QH group, fasting glucose level was significantly lower at 4th and 8th week(Fig 1A) , non-fasting blood glucose at the 4th week (1B) and GSP at the 12th week(1C) than HFD group. QHYH improved glucose tolerance by decreasing blood glucose level markedly at 15' and 30' after glucose load at the 4th week (1D). QHYH markedly decreased serum MDA concentrations(1F), increased serum CAT (1H) and SOD (1I) activities compared to HFD group only at the 4th week, however, GSH-Px activity(1G)was also markedly decreased. At the 16th week, neither glucose profile, nor glucose tolerance, nor serum MDA level or antioxidant enzyme activities was markedly different. Furthermore, in morphometry study, QHYH intervention did not restore the significant decrease of both beta cell mass and relative volume induced by high fat diet (ND vs HFD vs QH: 3.31±1.07mg vs 1.48±1.24mg vs 2.33±2.48mg, 27.6%±4.27% vs 19.4%±1.14% vs 18.1%±3.08%), nor with NT and 8OHdG staining.

Conclusions: QHYH improved glucose profile (4&8 weeks) and ameliorate oxidative stress (4 weeks) in GK rats fed with a high fat diet, which might be compromised by chronic glucotoxicity to pancreatic β cells





* P<0.05, **P<0.01 HFD-QH vs HFD (ANOVA-LSD)

Initial treatment with metformin + colesevelam provides greater glycaemic control than metformin alone in Hispanic patients with type 2 diabetes mellitus

E. Hernandez-Triana[1], W.T. Garvey[2], R.B. Goldberg[3], Y. Handelsman[4], V.A. Fonseca[5], M.R. Jones[6], S.L. Abby[6], M. Markiewicz[6], X. Jin[7], S. Misir[6], S. Nagendran[6], J. Rosenstock[8];
[1]Endocare Research Institute, Universidad del Rosario, Bogota, Colombia, [2]UAB Diabetes Research and Training Center, University of Alabama at Birmingham, USA, [3]University of Miami Miller School of Medicine, USA, [4]Metabolic Institute of America, Tarzana, USA, [5]Tulane University Health Sciences Center, New Orleans, USA, [6]Daiichi Sankyo, Inc., Parsippany, USA, [7]Daiichi Sankyo Pharma Development, Edison, USA, [8]Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA.

Background and aims: Colesevelam is indicated for glycemic control and LDL-C lowering in patients with type 2 diabetes mellitus (T2DM) and hypercholesterolemia, respectively. A 16-week (wk), randomized, double-blind, placebo-controlled, multinational study evaluated the effect of initial therapy with metformin + colesevelam in drug-naïve patients with T2DM.
Materials and methods: This post-hoc analysis evaluated the efficacy of metformin + colesevelam in a subpopulation of Hispanic patients (those self identified enrolled in Colombia, Mexico, and the US) included in the 16-wk study. Drug-naïve adults with T2DM (HbA_{1c} 6.5%-10.0%), LDL-C ≥2.6 mmol/L, and triglycerides (TG) <5.7 mmol/L were randomized 1:1 to metformin + colesevelam 3.75 g/d or metformin + placebo. Metformin was initiated at 850 mg/d and was uptitrated at Wk 2 to 1700 mg/d. Efficacy parameters included change in HbA_{1c} (primary) and LDL-C (secondary) from baseline to Wk 16. All efficacy analyses were performed with last observation carried forward at Wk 16.
Results: In total, 173 Hispanic patients were treated with metformin + colesevelam (n=85) or metformin + placebo (n=88). Mean baseline HbA_{1c} was 7.7% (metformin + colesevelam) and 7.6% (metformin + placebo). At Wk 16, the mean change from baseline in HbA_{1c} was significantly greater with metformin + colesevelam vs metformin + placebo (-1.2% vs -0.8%; treatment difference [TD]: -0.4%; *P*=0.001), resulting in significantly more patients achieving HbA_{1c} <7.0% (75% vs 56%; *P*=0.02). Metformin + colesevelam resulted in significantly greater mean reductions in LDL-C vs metformin + placebo (-22.8% vs -3.4%; TD: -19.4%; *P*<0.0001), resulting in significantly more patients achieving LDL-C <2.6 mmol/L (49% vs 14%; *P*<0.0001). There were significant LS mean changes from baseline with metformin + colesevelam vs metformin + placebo in non-HDL-C (-13.6% vs -3.3%; TD: -10.3%; *P*<0.0001), total cholesterol (-9.1% vs -1.2%; TD: -7.9%; *P*<0.0001), TG (median: 9.5% vs -11.1%; TD: 21.2%; *P*<0.0001), apoA-I (9.7% vs 5.4%; TD: 4.2%; *P*=0.01), and apoB (-11.4% vs -1.7%; TD: -9.8%; *P*<0.0001). Overall, metformin + colesevelam was well tolerated (Table).
Conclusion: Metformin + colesevelam may be an appropriate initial treatment option to improve glycemic and lipid control in Hispanic patients with T2DM.

Summary of Adverse Events

AEs occurring in ≥5% of patients, n (%)	Metformin + Colesevelam (n=89)	Metformin + Placebo (n=90)
Abdominal pain	5 (6)	7 (8)

Plasma 25-hydroxyvitamin D concentration and metabolic syndrome in Chinese individuals - Shanghai Changfeng Study

H. Lin[1], H. Ma[1], X. Li[1], J. Gao[1], B. Song[2], B. Pan[2], J. Sheng[3], X. Chen[3], X. Gao[1];
[1]Department of Endocrinology and Metabolism, Zhongshan Hospital, Fudan University, Shanghai, China, [2]Department of Laboratory Medicine, Zhongshan Hospital, Fudan University, [3]Shanghai Changfeng Community Health Care Center, Shanghai, China.

Background and aims: Several evidence suggests that 25-hydroxyvitamin D concentration is associated with metabolic syndrome (MetS), but the others consider that parathyroid hormone, but not vitamin D is related. We aimed to explore whether vitamin D or parathyroid hormone is associated with metabolic syndrome among a cross-sectional population of over 45 years old in Shanghai Changfeng community of China.
Materials and methods: The study population consisted of 538 inhabitants (40.5% men, median age 63.4 years) recruited from Changfeng community in Shanghai. A standard interview (included life style, diseases history through questionnaires). Anthropometrics (height, weight, waist and hip circumference, blood pressure), Laboratory parameters (including serum lipid, fasting plasma glucose [FPG], 2h postload plasma glucose [2hPG] after oral glucose tolerance test [OGTT], 25-hydroxyvitamin D and parathyroid hormone [Electrochemiluminescence assay, Roche E170], calcium and phosphorus) were conducted for each participant. Metabolic syndrome was defined using International Diabetes Federation criteria for Chinese.
Results: 495 inhabitants (40.4% men, median age 63.2 years) had completed data were included into analysis. The mean of plasma 25-hydroxyvitamin D concentration was 45.00±15.58nmol/l in this population. The frequency of metabolic syndrome is 33.7% (27.0% in men and 38.3% in women). Subjects with MetS had lower 25-hydroxyvitamin D concentration than those individuals without MetS (42.67nmol/l vs 46.18nmol/l, *P*=0.017). Compared with the highest tertile of 25-hydroxyviatamin D concentration(≥49.46nmol/l), the Odds ratio for metabolic syndrome in the middle (37.38-49.46nmol/l) and lowest tertile of 25-hydroxyviatamin D (≤37.38nmol/l) was 1.29 and 1.47 (95% CI 0.81-2.05 and 0.93-2.33) respectively. We observed that metabolic syndrome was negative associated with 25-hydroxyvatamin D (OR=0.963, 95%CI 0.945-0.981) in the logistic regression analysis. Significant inverse associations also existed between 25-hydroxyviatamin D concentration and metabolic syndrome (OR=0.941, 95%CI 0.901-0.983) when plus parathyroid hormone, blood calcium and phosphorus into model.
Conclusion: The occurrence of metabolic syndrome had increasing trend with the decline in the level of 25-hydroxyvitamin D. Lower 25-hydroxyvitamin D level is significantly associated with an increased risk of metabolic syndrome independent of parathyroid hormone in this Chinese population.

Effects of RSG/MET FDC on glycaemic control and BMD after 80 weeks of treatment in drug-naïve type 2 diabetes mellitus subjects

A.J. Nino[1], J. Bilezikian[2], J. Borges[3], P.L. Adams[1], A.R. Jones[1], A. Acusta[1], P. Ambery[4], A. Cobitz[1], L.A. Fitzpatrick[5];
[1]MDC CVM, GlaxoSmithKline, King of Prussia, USA, [2]College of Physicians & Surgeons, Columbia University, New York, USA, [3]Clínica de Endocrinologia e Metabologia, Brasílla, Brazil, [4]MDC CVM, GlaxoSmithKline, Harlow, United Kingdom, [5]Biopharm R&D, GlaxoSmithKline, King of Prussia, USA.

Background and aims: Avandamet is a fixed-dose combination tablet comprised of rosiglitazone (RSG) and metformin (MET), which have complementary modes of action. Clinical studies have suggested that earlier use of combination therapy may improve long-term glycemic control. The purpose of this study (CT.gov NCT00386100) was to assess if RSG/MET significantly lowers A1c compared to MET alone, and if glycemic effects attained with AVM are durable over 80 weeks. A bone sub-study was added to this trial to further investigate the effects of RSG/MET on bone in light of an increased fracture rate in female subjects who received RSG in the ADOPT study. Presently, understanding of the clinical significance of these findings is incomplete, and the mechanism(s) for the observed increase in fractures are uncertain.
Materials and methods: In this double-blind, randomized study, RSG/MET was compared to MET in drug-naïve T2DM subjects with A1c ≥7.5% to ≤10.5%. Subjects (n=688) were randomized to either RSG/MET 4/500mg (max daily dose, 8/2000mg) or MET 500mg (max dose, 2000mg) and were assessed for 80 weeks. Doses were titrated at 4-week intervals up to Week 20 (unless mean daily glucose was <100mg/dL) and at 12-week intervals from Weeks 32 to 80 (unless A1c ≤6.5%). BMD by DXA at lumbar spine, total hip, femoral neck, trochanter, distal radius, and total body were assessed at Weeks 0, 20, 56 & 80.
Results: RSG/MET (-1.9%) was superior to MET (-1.4%) with respect to mean change from baseline A1c at Week 80 (-0.50%, p<0.0001). RSG/MET showed significant improvements in insulin sensitivity (HOMA-%S) at 80 weeks compared to MET alone (% treatment difference: 31.1%, p<0.0001). There were significantly greater reductions in fasting insulin, c-peptide, and free fatty acids for RSG/MET vs MET. No statistically significant between-group BMD reductions occurred in femoral neck, distal radius, or total body. Significant between-group BMD changes at Week 80 occurred at: lumbar spine in the overall, total female, and post-menopausal female groups; trochanter in the overall and total female groups; and total hip in all subgroups except post-menopausal females. MET alone was not associated with significant bone loss for the duration of the trial. Both agents were generally well-tolerated: withdrawals due to an AE occurred in 7% (25/344) and 5% (15/334) of RSG/MET and MET subjects. There were a total of nine on-therapy fractures (5 for RSG/MET, 4 for MET) reported as AE/SAEs. In the overall study, there were no unexpected adverse events.
Conclusion: RSG/MET significantly reduced A1c vs MET and maintained glycemic control over 80 weeks. These data confirm that RSG/MET is superior to MET in improving insulin sensitivity in drug-naïve subjects with T2DM. The observed BMD changes may be relevant to fracture risk in this population.

Efficacy and safety of repaglinide and metformin combination therapy compared to repaglinide monotherapy in Chinese oral anti-diabetic drug (OAD) naïve type 2 diabetic patients

W. Wang[1], G. Ning[1], Q. Su[2], J. Liu[3], R. Bu[4], AGEE3705 Study Group;
[1]Shanghai Jiaotong University Affiliated Ruijin Hospital, Shanghai, [2]Shanghai Jiaotong University Affiliated Xinhua Hospital, Shanghai, [3]The First Affiliated Hospital of Nanchang University, Nanchang, [4]Wuxi People's Hospital, Wuxi, China.

Background and aims: The ADA and EASD recommend early initiation of combination therapy when HbA_{1c} > 8.5 %. Combination therapy with repaglinide and metformin is a good treatment option for type 2 diabetes. This trial was designed to investigate the efficacy and safety of this combination treatment compared to repaglinide monotherapy in Chinese OAD naïve type 2 diabetic patients with HbA_{1c} > 8.5 %.
Materials and methods: This was a 16-week, open-label, multicentre, randomised, active-controlled, parallel study involving 17 sites in China. Subjects were randomised 1:1 to receive either repaglinide in combination with metformin (1 mg/500 mg QD) or repaglinide alone (1mg TID), and then underwent a 6-week dose titration period followed by a 10-week maintenance period. During the dose titration period, subjects whose fasting plasma glucose (FPG) ≥ 6.1 mmol/L without clinically unacceptable hypoglycaemic episodes continued to titrate the daily dose until the FPG target of 4.4-6.1 mmol/L or the maximum recommended daily dose (repaglinide/metformin 4mg/500mg, TID; repaglinide 4 mg, TID) was reached.
Results: A total of 432 subjects (female 313, mean ± SD: age 49.9 ± 10 years, BMI 24.5 ± 3.0 kg/m^2, HbA_{1c} 10.8 ± 1.5 %) were exposed to trial drugs. After 16-weeks treatment, the glucose control was improved in both groups. Mean HbA_{1c} decreased from 10.9 ± 1.5 % at baseline to 6.4 ± 1.1 % at 16 weeks in the combination therapy group, and from 10.7 ± 1.5 % to 6.7 ± 1.0 % in the monotherapy group. The mean reduction was 4.5 ± 1.6 % point and 4.1 ± 1.6% point, respectively (P = 0.002). HbA_{1c} < 7 % was achieved in 78.9 % of the subjects with combination therapy, and in 69.6 % of those with repaglinide alone (P = 0.010). Compared to monotherapy, the combination treatment also achieved a superior outcome in FPG, 2-hour postprandial plasma glucose, mean 7-point plasma glucose, and mean prandial plasma glucose increment (Table). No major hypoglycaemia was reported during the trial, and the overall hypoglycaemia rate was 2.04 events per subject year in the combination treatment group and 1.35 events per subject year in the monotherapy group (P = 0.058). Adverse events reported during the trial were comparable between groups. At the end of the trial, mean weight gain was small in both groups; 0.2 ± 0.2 (mean ± SD) kg in the combination therapy group and 0.5 ± 0.2 kg in the monotherapy group, respectively (P = 0.322).
Conclusion: Combination therapy with repaglinide and metformin and repaglinide monotherapy improved glucose control significantly in OAD naïve Chinese type 2 diabetic patients with baseline HbA_{1c} > 8.5 %. However, combination treatment provided superior glycaemic control compared to repaglinide monotherapy. The safety profile was comparable between groups.

Comparision of glucose control parameters between groups

Glucose control parameters (mean ± SD), mmol/L		Baseline	After 16-week treatment	Change from baseline
Fasting plasma glucose	Repaglinide + Metformin	11.30 ± 3.20	6.34 ± 1.50**	-4.98 ± 3.23**
	Repaglinide	11.23 ± 3.56	6.71 ± 1.72**	-4.44 ± 3.50**
2-hour postprandial plasma glucose after breakfast	Repaglinide + Metformin	17.08 ± 5.34	9.18 ± 3.46	-7.86 ± 5.93
	Repaglinide	16.96 ± 5.24	9.61 ± 3.23	-7.30 ± 5.57
Mean 7-point plasma glucose	Repaglinide + Metformin	14.27 ± 3.93	7.39 ± 1.76**	-6.84 ± 3.95**
	Repaglinide	14.03 ± 3.86	8.16 ± 2.13**	-5.86 ± 3.82**

Metformin therapy and outcomes of viral C cirrhosis in type 2 diabetic patients. A retrospective study

G. Nkontchou[1], P. Valensi[2], M. Aout[3], N. Ganne-Carrie[1], V. Grando-Lemaire[1], E. Vicaut[3], J.-C. Trinchet[1], M. Beaugrand[1], E. Cosson[2];
[1]Hepato-Gastro-Enterology, Jean Verdier Hospital, BONDY, [2]Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, BONDY, [3]Direction de la Recherche Clinique, Fernand Widal Hospital, Paris, France.

Background and aims: Insulin resistance seems to play a crucial role in the poor prognosis associated with overweight and obesity for viral C cirrhosis. The aim of the study was to retrospectively examine whether metformin therapy (which activates AMP kinase and decreases insulin resistance) may be associated with a better prognosis in patients with type 2 diabetes.
Materials and methods: Between 1988 and 2007, 100 consecutive diabetic patients, 53 men, 61±11 years old, body mass index 27±5 kg/m^2, with ongoing viral C infection and cirrhosis were included in a screening program for

hepato-cellular carcinoma (HCC) detection including serum alpha foeto protein (AFP) measurement and ultrasound examination every 3 to 6 months. The patients were followed up for HCC and liver related death or hepatic transplantation.
Results: Diabetic patients were treated either by metformin (n=22) or not (insulin (n=28), insulin secretory drugs (n=20) or diet alone (n=30)). No statistically significant difference was observed at inclusion between the two groups. During a mean follow-up of 5.9±4.4 years, 38 patient developed an HCC and 38 had a liver related death. The 5-year HCC incidence was 10.9% and 29.8% in patients who received metformin or did not receive metformin respectively (log rank 7.47, p=0.006). In multivariate analysis, metformin treatment was associated with a reduced incidence of HCC (Odds ratio 0.23 [95% CI 0.06-0.96], p=0.04) whereas age (OR 2.33 [1.14-4.77], p=0.02) and serum AFP level (OR 1.02 [1.01-1.03], p=0.005) were predictive of HCC occurrence. Metformin therapy was also associated with a lower incidence of liver related deaths or transplantation (log rank 6.3, p<0.05).
Conclusion: In diabetic patients with cirrhosis and persistent HCV infection, metformin use is associated with a reduced risk of HCC occurrence and liver related death or transplantation.

899

Treatment with pioglitazone plus insulin is well tolerated and shows metabolic benefits compared to a combination of insulin and metformin. Interim results from the PIOcomb study

A. Pfützner[1], M. Hanefeld[2], C. Hohberg[1], C. Köhler[2], J. Müller[3], T. Forst[1]; [1]IKFE Institute for Clinical Research and Development, Mainz, [2]GWT, Dresden, [3]Acromion, Frechen, Germany.

Background and aims: Addition of basal insulin to oral therapy in type 2 diabetes (basal insulin supported oral therapy, BOT) is a very common therapeutic strategy in Germany. Our investigation aimed at comparing a pioglitazone plus insulin (PI) regime with a metformin plus insulin (MI) treatment, and with triple therapy (PMI). Observation parameters included glycemic control, insulin sensitivity, insulin consumption, beta-cell preservation, and the intensity of chronic systemic inflammation.
Materials and methods: In an interim analysis of the double-blinded, multicentre PIOcomb study, we included 78 type 2 diabetic patients with previous insulin therapy (52 men, 26 women, age [mean±SD]: 63±8 years, BMI: 32.7±5.6 kg/m^2, diabetes duration: 9±5 years, HbA1c: 7.3±0.5%). Patients received an optimised and individualised regimen with insulin glargine (titration) and were randomised to an additional treatment with pioglitazone (2 x 15 mg/day) or metformin (2 x 850 mg/day), or a combination of both oral antidiabetic drugs. Efficacy parameters (HbA1c, insulin dosage, HOMA score, intact proinsulin, adiponectin, and hs-CRP) were assessed at baseline and after a six-month observation period.
Results: HbA1c remained stable in the dual therapy groups, and decreased in the PMI treatment arm (PI/MI/PMI: -0.1±0.6 %/-0.1±0.7 %/-0.5±0.6 %, p<0.05 vs. baseline). Improved insulin sensitivity was only demonstrated in the two groups receiving pioglitazone. The baseline and endpoint values of the observation parameters are provided in the Table. There were no differences in the reported number of hypoglycemic events between the groups (8/8/10).
Conclusion: Addition of metformin and/or pioglitazone to a basal insulin therapy with insulin glargine provided stable metabolic control in all cases, without increasing the risk for hypoglycemia. A significant improvement in insulin resistance and cardiometabolic syndrome, as indicated by related biomarkers and a reduction in daily insulin dose, was only observed with pioglitazone administration.

Observation parameters at baseline and endpoint (*: p<0.05 vs. baseline)

Parameter	MI	(n=25)	PI	(n=28)	PMI	(n=25)
	baseline	endpoint	baseline	endpoint	baseline	endpoint

Comparison of the effects of pioglitazone vs. placebo when given in addition to standard insulin treatment in patients with type 2 diabetes mellitus requiring haemodialysis: interim results from the PIOren study

J. Galle[1], V.H.R. Schmid[2], C. Forkel[2], T. Forst[2], A. Pfützner[2]; [1]Klinikum Lüdenscheid, [2]IKFE - Institute for Clinical Research and Development, Mainz, Germany.

Background and aims: Patients with type 2 diabetes mellitus and clinically significant kidney disease are usually treated with insulin. However, the modified pharmacokinetic insulin profile and vascular insulin resistance in patients with delayed renal insulin elimination frequently impairs a successful therapy and, additionally, results in increased oxidative stress and cardiovascular risk. Therefore, the aim of this study was to investigate the effect of the insulin sensitizer pioglitazone (PIO) vs. placebo treatment on total daily insulin requirements and the overall metabolic status in type 2 diabetes patients with renal failure requiring hemodialysis.
Materials and methods: The effect of pioglitazone (30 mg) vs. placebo was explored by an interim analysis of this multi-centre, randomized, double-blind study in 23 patients with Type 2 diabetes and kidney failure and dialysis therapy (16 male, 7 female, age (mean±STD): 68.2±8.8 yrs., HbA1c: 7.5±0.8 %, disease duration: 11.8±8.5 yrs.). Efficacy parameters collected before dialysis and after an overnight fast at baseline and after 6 months were: total daily insulin dose, HbA1c, fasting blood glucose, adiponectin, HDL, LDL, triglycerides, NT-proBNP and ultra filtrate volume.
Results: Application of PIO resulted in a significant decrease in insulin resistance as indicated by a reduction in daily insulin dose by 32 % (p<0.05 vs. baseline; placebo: -5 %., n.s.), and clinically relevant improvements in HbA1c (-0.62±0.75 %, p<0.01; placebo: +0.57±1.08 %, n.s.), fasting glucose (-56±73 mg/dl, p<0.05 vs. +20±35 mg/dl, n.s.), adiponectin (+6.9±8.4 mg/l, p<0.01 vs. +1.0±6.5 mg/l, n.s.), and triglycerides (-111±178 mg/dl, p<0.05 vs. +65±70 mg/dl, p<0.05). Slight improvements or no changes were seen with HDL, LDL, NTproBNP and the ultra filtrate volume. The absolute values at baseline and endpoint are provided in the Table.
Conclusion: Addition of pioglitazone to insulin in hemodialysis patients was well tolerated. Without changing the ultra filtrate volume, treatment with pioglitazone in addition to insulin in patients with late stage kidney failure requiring hemodialysis was associated with a lower insulin dose and with an improved glycaemic control and lower triglyceride levels, indicating a potential impact of pioglitazone on the long-term disease prognosis in late stage diabetes.

Observation parameters at baseline and endpoint (*: p<0.05 vs. baseline)

Parameter	Pioglitazone	(n = 14)	Placebo	(n = 9)
	Baseline	6 months	Baseline	6 months

PIOcomb study interim analysis: Pioglitazone added to insulin treatment reduces chronic systemic inflammation in patients with type 2 diabetes

B. Stratmann[1], T. Forst[2], A. Pfützner[2], J. Müller[3], D. Tschöpe[1], M. Hanefeld[4]; [1]Heart and Diabetes Center, Bad Oeynhausen, [2]IKFE - Institute for Clinical Research and Development, Mainz, [3]Acromion, Frechen, [4]GWT, Dresden, Germany.

Background and aims: Combination therapy with insulin glargine and metformin is a common therapy in type 2 diabetes. The purpose of the PIOcomb study was to investigate, whether use of pioglitazone instead of metformin has additional impact on the underlying disease pathophysiology, and in particular on chronic systemic inflammation (CSI). CSI leads to macrovascular complications, the major cause of mortality in patients with type 2 diabetes.

Materials and methods: Here we report on an interim analysis of the double-blinded, multicentre PIOcomb trial (78 patients with previous insulin therapy, 52 men, 26 women, age [mean±SD]: 63±8 years, BMI: 32.7±5.6 kg/m^2, diabetes duration: 9±5 years, HbA1c: 7.3±0.5%). Patients were switched for 6 months to an individualised once daily insulin glargine injection (with forced titration to normal fasting glucose values) and were additionally randomised to receive either pioglitazone (PI; 2 x 15 mg/day), or metformin (MI; 2 x 850 mg/day), or a combination of both oral antidiabetic drugs (PMI). Efficacy parameters for this analysis (determined at baseline and after 24 weeks) were HbA1c, MMP9, hsCRP, E-selectin, fibrinogen, PAI-I, nitrotyrosine, and the NFkB mRNA expression of peripheral circulating monocyte/macrophages.
Results: Daily insulin dose increased with MI and decreased with PI and PMI, which was associated with stable or improved glycemic control (HbA1c, PI/MI/PMI: -0.1±0.6 %/-0.1±0.7 %/-0.5±0.6 %, PMI: p<0.05 vs. baseline). With PI and PMI, there were significant reductions in hsCRP and E-selectin and improvements were also seen for macrophage activation (NFkB) with PI and PAI-I with PMI. All other parameters showed tendencies for improvement with PI and PMI that did not reach the level of statistical significance. The baseline and endpoint values are provided in the Table. None of these beneficial changes were seen with MI treatment.
Conclusion: While reaching comparable glycemic control (compared to metformin) with lower insulin requirements, addition of pioglitazone to insulin glargine improved several biomarkers of chronic systemic inflammation and vascular function in patients with Type 2 diabetes. This may translate into a lower macrovascular mortality as has been previously indicated in the PROactive study.

Observation parameters at baseline and endpoint (*: p<0.05 vs. baseline)

Parameter	MI	(n = 25)	PI	(n = 28)	PMI	(n = 25)

Effect of acarbose on inflammatory parameters at baseline and after an oral fat load: a double-blind, placebo controlled trial
P. Maffioli, S.A.T. Salvadeo, I. Ferrari, A. Gravina, R. Mereu, A. D'Angelo, I. Palumbo, S. Randazzo, G. Derosa;
Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S.Matteo, Italy.

Background and aims: To evaluate the effects of acarbose compared to placebo on inflammatory biomarkers in diabetic patients at baseline and after a standardized oral fat load (OFL).
Materials and methods: A multicenter, randomised, double-blind, controlled study was conducted; 188 type 2 diabetic patients were randomised to titrate acarbose til 100 mg three times a day or placebo. We evaluated at the baseline, and after 1, 2 and 7 months: body mass index (BMI), glycemic profile, fasting plasma insulin (FPI), post-prandial plasma insulin (PPI), homeostasis model assessment index (HOMA index), lipid profile, soluble intercellular adhesion molecule-1 (sICAM-1), interleukin-6 (IL-6), high-sensitivity C reactive protein (Hs-CRP), soluble vascular cell adhesion molecule-1 (sVCAM-1), soluble E-selectin (sE-selectin). Furthermore, at the baseline and at the end of the study, all patients underwent OFL. Repeated measures analysis of variance (ANOVA), analysis of covariance (ANCOVA), and paired tests were used: a one-sample t test and two-sample t tests.
Results: We observed a significant decrease of body weight, and BMI in both groups (p<0.05, for both). An improvement of glycemic profile was observed in both groups, but acarbose gave a faster and better decrease of these parameters compared to placebo (p<0.01 for glycated hemoglobin, and p<0.05 for fasting and post-prandial glucose). No variation of FPI, or PPI were observed in control group, while there was a reduction of these parameters after 7 months with acarbose (p<0.05), even if no differences between the two treatments were recorded. Acarbose reduced HOMA index after 3, and 7 months (p<0.05, and p<0.01, respectively), while no modifications were registered in controls; moreover HOMA index obtained with acarbose was significantly lower than the value in control group (p<0.05). Neither of treatments influenced HDL-cholesterol; instead acarbose significantly reduced total cholesterol (p<0.05), and LDL-cholesterol (p<0.05) after 7 months compared to baseline, and with control group (p<0.05). No variation of tryglicerides (Tg) was reached in controls, while acarbose decreased Tg value after 3, and 7 months compared to baseline (p<0.05, and p<0.01, respectively), and with controls (p<0.05). We did not observe any variation of s-ICAM-1, sVCAM-1, IL-6, and Hs-CRP in controls, while there was a reduction of these parameters with acarbose (p<0.05 for all), even if no differences were obtained between the two groups. No variation of E-selectin was recorded in neither of groups. Regarding OFL, there was a decrease of blood glucose levels in both groups comparing OFL administered at baseline, and at the end of the study. There was an improvement of all lipid parameters in acarbose group, while there was only a reduction of Tg in control group. A reduction of sICAM, sVCAM, IL-6, Hs-CRP, and sE-Selectin was registered in both groups, even if acarbose had a longer effect in reducing inflammatory parameters during OFL.
Conclusion: Acarbose gave a faster and better improvement of glycemic, lipid profile and inflammatory parameters compared to placebo. Regarding OFL, acarbose had a longer effect in reducing inflammatory parameters compared to controls.

903

Acarbose compared to placebo on insulin resistance biomarkers in a double-blind, placebo-controlled trial
G. Derosa, S.A.T. Salvadeo, I. Ferrari, A. Gravina, R. Mereu, A. D'Angelo, I. Palumbo, S. Randazzo, P. Maffioli;
Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S.Matteo, Italy.

Background and aims: To evaluate the effects of acarbose compared to placebo on insulin resistance biomarkers in a randomised, double-blind, placebo controlled trial.
Materials and methods: We randomised 188 type 2 diabetic patients to titrate acarbose til 100 mg three times a day or placebo. We evaluated: body mass index (BMI), glycated hemoglobin (HbA_1c), fasting plasma glucose (FPG), post-prandial plasma glucose (PPG), fasting plasma insulin (FPI), post-prandial plasma insulin (PPI), homeostasis model assessment index (HOMA index), lipid profile, tumor necrosis factor-α (TNF-α), resistin (r), retinol binding protein-4, adiponectin (ADN), high-sensitivity C reactive protein (Hs-CRP) at the baseline, and after 1, 2 and 7 months. Furthermore, at the baseline and at the end of the study, all patients underwent euglycemic hyperinsulinemic clamp to evaluate M value and total glucose requirement (TGR); an oral fat load (OFL) was also performed at baseline, and after 7 months of therapy. Repeated measures analysis of variance (ANOVA), analysis of covariance (ANCOVA), and paired tests were used: a one-sample t test and two-sample t tests.
Results: We observed a significant decrease of body weight and BMI in both groups (p<0.05 for both). An improvement of $HbA_{1c,}$ FPG, and PPG was reached in both groups, even if acarbose gave a faster and better improvement of these parameters compared to placebo (p<0.01 for $HbA_{1c,}$ and p<0.05 for both FPG, and PPG). Placebo did not reduce FPI, or PPI, while acarbose decreased these parameters after 7 months of therapy (p<0.05), even if no differences between the two treatments were recorded. Acarbose significantly reduced HOMA index compared to baseline after 3, and 7 months (p<0.05, and p<0.01 respectively), and with controls after 7 months (p<0.05). Acarbose significantly decreased total cholesterol (p<0.05), tryglicerides (Tg) (p<0.01), and LDL-cholesterol (p<0.05) after 7 months compared to baseline, and with controls (p<0.05). We did not observe any variation of TNF-α in neither of groups. We obtained a reduction of r, and Hs-CRP after 7 months with acarbose (p<0.05, for both) but not with placebo, even if no differences were recorded in group to group comparison. Moreover, acarbose, but not placebo, gave a decrease of RBP-4, and an increase of ADN compared to baseline (p<0.05 for both), and the values obtained at 7 months were significantly better than the values obtained in control group (p<0.05). Regarding OFL, there was a decrease of blood glucose levels in both groups during OFL administered at the end of the study compared to OFL at baseline. There was an improvement of all lipid parameters in acarbose group, while there was only a decrease of Tg in control group. A reduction of RBP-4, TNF-α, and Hs-CRP,

and an increase of ADN were observed in both groups, even if acarbose had a longer effect in reducing inflammatory parameters during OFL. We reached an increase of M value, and TGR after 7 months ($p<0.05$ for both) with acarbose, but not with placebo.
Conclusion: We reached a faster and better improvement of glycemic and lipid profile with acarbose compared to placebo. Acarbose also improved insulin resistance biomarkers, while placebo did not decrease these parameters. Regarding OFL, acarbose had a longer effect in improving insulin resistance compared to control group.

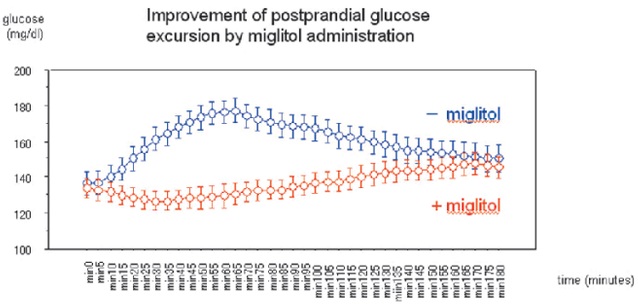
Efficacy of miglitol on postprandial glucose control assessed by continuous glucose monitoring

S. Nagasaka[1], T. Tsuchita[1], N. Takahashi[1], D. Sekizawa[1], N. Saito[1], K. Okada[1], I. Kusaka[1], H. Yagyu[1], H. Ogata[2], S. Ishibashi[1];
[1]Endocrinology and Metabolism, Jichi Medical University, Shimotsuke, [2]Graduate School of Education, The University of Tokyo, Bunkyo-ku, Japan.

Background and aims: α-glucosidase inhibitors improve postprandial glucose control, but their precise efficacy has not been evaluated by continuous glucose monitoring (CGM). The present study was undertaken to reveal efficacy of miglitol on postprandial glucose control.
Materials and methods: Nineteen diabetic subjects (4 with type 1 and 15 with type 2; with ages of 58±11yrs, BMI 22.8±3.2kg/m^2, HbA1c 9.1±2.5%, glycated albumin 24.5±6.3%, and 1, 5-anhydroglucitol 6.5±3.9μg/ml, mean±SD, respectively) were studied with CGM on 2 consecutive days. By a cross-over manner, their usual therapies (10 with multiple insulin injections, 4 with oral hypoglycemic agents, and the remaining 5 with diet therapy alone) were rendered on one day, and miglitol 150mg/day was additionally administered on another day. These measurements were performed while the patients were admitted and given controlled diet comprising 50% of energy intake as carbohydrate.
Results: Averaged glucose levels on their usual therapies were 137±49 (pre-prandial), a peak of 177±49 observed at 60 min postprandial, and then the levels were gradually decreased to 151±57 mg/dl (at 180 min). The glucose levels on miglitol administration were 134±43 mg/dl (pre-prandial), and thereafter no apparent peak was observed until 180 min (P=0.0015 by two-way repeated-measures ANOVA, Figure). There were also significant differences in glucose levels from 20 to 120 min postprandial between these two situations. On their usual therapies, pre-prandial glucose levels at breakfast, lunch, and supper were 136±52, 136±48, and 137±52 mg/dl, and maximal postprandial levels were 181±49 (at 65), 160±51 (at 65), and 192±42 mg/dl (at 55), respectively. By miglitol administration, postprandial glucose levels displayed essentially similar pattern as shown in Figure, so that the efficacy of miglitol was most evident after dinner. Some of the measures of glycemic variability assessed by CONGA (Diabetes Technol Ther 7: 253, 2005) were improved by miglitol administration.
Conclusion: Postprandial glucose levels were significantly reduced from as early as 20 min and until 120 min by miglitol administration. The efficacy was most evident after dinner.



905

Gliclazide blocks cytotoxic effect of hydrogen peroxide

A. Sliwinska[1], A. Rogalska[2], Z. Jozwiak[2], J. Kasznicki[1], J. Drzewoski[1];
[1]Department of Internal Disease, Diabetology and Clinical Pharmacology, Medical University of Lodz, Zgierz, [2]Department of Thermobiology, University of Lodz, Poland.

Background and aims: Apoptosis, a programmed cell death, is needed to maintain homeostasis of the cell under physiological condition. However, this process can be induced under pathological conditions such as an increase in reactive oxygen species (ROS) production in the mitochondria. It is believed that ROS-induced apoptosis is responsible for loss of beta cell mass in diabetes. It was found that gliclazide - a member of sulfonylureas group- may protect pancreatic beta cells against apoptosis induced by oxidative stress. The aim of our study was to explore the antiapoptotic action of gliclazide *in vitro*.
Materials and methods: Evaluation of the impact of gliclazide on apoptosis induced by hydrogen peroxide of pancreatic and mammary gland tumor cells (PANC-1 and Hs578T) was assessed by the 1-(4,5-Dimethylthiazol-2-yl)-3,5-diphenylformazan (MTT) colorimetric assay and the neutral red uptake (NRU) cytotoxicity assay. The effect of gliclazide on the level of ROS was measured by the 2',7'-dichlorodihydrofluorescein diacetate (DCFH2-DA) assay. N-acetylcysteine (NAC), that possesses antioxidant properties similarly to gliclazide, was used as a control.
Results: We observed that hydrogen peroxide induced a concentration- and time-dependent loss of viability of PANC-1 and Hs578T cells. Gliclazide significantly diminished cytotoxic effect of hydrogen peroxide on both cell lines. It was also found that either gliclazide and NAC inhibited generation of ROS in both cell lines. Interestingly, there were not significant differences in inhibition of ROS generation between gliclazide and NAC after 24 h incubation. However, NAC was more sufficient after 72 h incubation than gliclazide (Figure).
Conclusion: Our findings indicate that gliclazide may prevent cells from cytotoxic effect of hydrogen peroxide by decreasing the generation of ROS. These results support previous observations suggesting protective effect of this antidiabetic drug on beta-cells loss. However, further studies are needed to evaluate the mechanism(s) of protective effects of gliclazide against oxidative stress induced apoptosis.

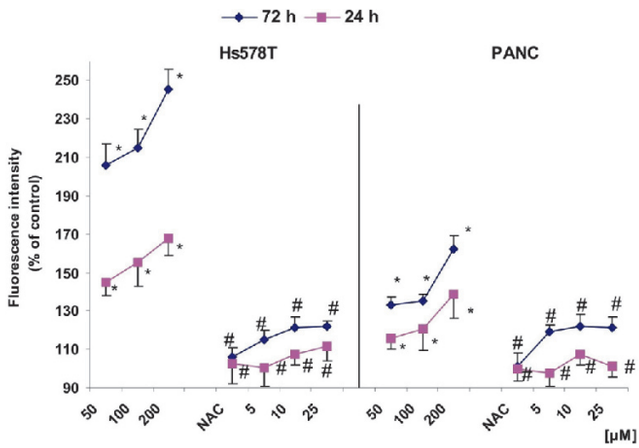


Figure. Induction of ROS by H2O2 in Hs578T and PANC cells in the presence and absence of antioxidant-NAC or gliclazide. The cells (10^4), seeded into 96-well microplates 24 h before the experiment, were treated with different H2O2 concentrations for 24 h or 72. Oxidation of 5 μM DCFH2-DA fluorescence probe was used for monitoring the produced ROS after drug treatment. In experiments with antioxidant or gliclazide, cells treated with 200 μM of H2O2 were preincubated with 3 mM NAC or 5-25 μM gliclazide for 1 h, then H2O2 was added and incubation was continued for another 24 h or 72 h. The results represent mean ± SD of four independent experiments. *P<0.05 in comparison to respective control cells taken as 100%, #P<0.05 indicates significant differences between H2O2-treated cells and samples preincubated with NAC or gliclazide.

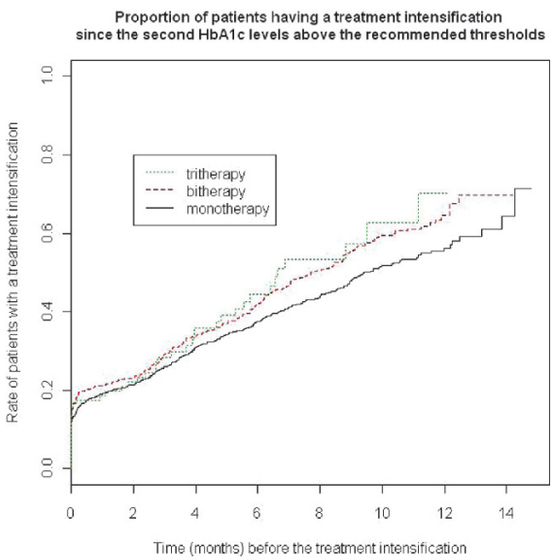
Uncontrolled type 2 diabetes treated with oral hypoglycaemic agents (OHA): therapeutic behaviour in primary care in France

B. Detournay[1], B.J. Balkau[2], S. Halimi[3], J.-F. Blickle[4], I. Chartier[5], E. Tocque[6], E. Amelineau[7];
[1]CEMKA-EVAL, Bourg La Reine, [2]Inserm U780-IFR69, Villejuif, [3]CHU Michalon, Grenoble, [4]Hôpital Civil de Strasbourg, [5]AIXIAL Pharma, Levallois-Perret, [6]AstraZeneca, Rueil Malmaison, [7]Bristol-Myers Squibb, Rueil Malmaison, France.

Background and aims: Current diabetes guidelines recommend that treatment should be intensified according to the HbA1c level. In France, HbA1c thresholds vary according to treatment patterns: mono-, bi- or tritherapy with OHA or with insulin. Recent epidemiologic data have confirmed that intensified therapies are still underused. The study objectives were: to identify the proportion of type 2 diabetic (T2D) patients with intensified treatment among those who needed such intensification according to HbA1c levels, to measure the time to intensification, to identify the factors related with this delay.
Materials and methods: A retrospective analysis was performed on a cohort of T2D patients from a large computerised longitudinal database in primary care. Patients analyzed were adult T2D patients, treated with OHA without insulin therapy or GLP-1 mimetic. Time to treatment intensification was measured from the last of two successive HbA1c levels above the recommended thresholds in France (6.5% for patients treated with a monotherapy, 7.0% for bitherapy and 8.0% for tri and quadritherapy). Treatment intensification was defined as an increase in the number of drug classes or an increased dose of the class being used or the introduction of insulin therapy or GLP-1 mimetic. Switches to a different class were not considered. Predictive factors were identified by Cox regression multivariate models.
Results: In the overall sample of 17,493 patients treated with OHA without insulin therapy or GLP-1 mimetic, 3,118 (18%) were identified as requiring a treatment intensification. Such intensification was performed respectively for 39% and 60% of those patients within a 6-month period and within a one-year period following the date of the second HbA1c value: 38% and 56% for patients treated with a monotherapy, 42% and 65% for patients treated with a bitherapy and 44% and 70% treated with a tritherapy. The rate of treatment intensification over time is positively correlated with HbA1c levels and with OHA treatment (bi- and tritherapy as compared to monotherapy) and negatively correlated with the age of the patient. No other explanatory variables related to the patients or to the physicians were identified.
Conclusion: With regard to current guidelines in T2D France, treatment intensification is still underused in primary care in France. Adherence to the guidelines appears to be mainly restrained by the age of the patient, with older patients being prescribed less frequently intensive treatment. Future guidelines should consider those points.



907

Patterns of use of glucose lowering treatments at baseline and during follow-up in ADVANCE

S. Czernichow[1], S. Zoungas[2], J. Chalmers[2], A. Patel[2], M. Marre[3], S. Colagiuri[4], P. Hamet[5], Q. Li[2], L. Billot[2];
[1]INSERM 557, University Paris 13, Hôpital Avicenne, Bobigny, France, [2]The George Institute for International Health, The University of Sydney, Australia, [3]Hôpital Bichat-Claude Bernard and Université, Paris, France, [4]Boden Institute of Obesity, Nutrition and Exercise, The University of Sydney, Australia, [5]Centre Hospitalier de l'Universite de Montreal and Universite de Montreal, Canada.

Background and aims: The ADVANCE and UKPDS trials are the only two large scale glucose lowering trials that have separately reported major benefits on cardiovascular and renal outcomes. Both used glucose lowering regimens that were based on sulphonylureas with addition of other drugs as required. In the present analyses we examine the patterns of use of various glucose lowering treatments at entry to ADVANCE and during follow-up.
Materials and methods: The treatment patterns applied to all 11,140 patients randomized to receive either gliclazide modified release (MR)-based intensive glucose control, targeting a mean glycated hemoglobin (HbA1c) of <=6.5% (n=5,571), or standard guideline based glucose control (n=5569) were analyzed both at baseline and during follow-up.
Results: At baseline, 9% of patients were managed with diet and lifestyle alone, 43% were receiving a single oral glucose lowering agent, 42% were receiving two oral agents and 6% were receiving three or more oral agents. 72% were on a sulphonylurea, 61% on metformin, and only 4%, 9% and 2% on thiazolidinediones, acarbose and glinides respectively. Of the patients on monotherapy at baseline, 59% and 38% were on sulphonylureas and metformin respectively. The median duration of follow up was 5.0 years. In the group assigned intensive glucose control, the HbA1c fell gradually to the target of <=6.5% after 36 months and was maintained till the end of the study. By the end of follow-up, 91% of patients in the intensive control group were still on gliclazide MR (average daily dose of 103mg/day) and 59% of patients in the standard control group were on other sulphonylureas. At that time, 74% and 67% of patients were taking metforminin the intensive and standard glucose control groups respectively. Less than half of the subjects in the intensive control group required insulin by the end of follow-up (40%). The average time to the introduction of insulin in the intensive group was 44 months, considerably later than the 36 months taken to achieve the HbAlc target of 6.5%.
Conclusion: The gliclazide MR-based intensive glucose control regimen achieved its target HbA1c of 6.5% within 3 years and maintained it to the end of 5 years of follow-up. At baseline, sulphonylureas were taken by 72% of all patients and at the end of follow-up by 91% of patients in the intensive glucose control group and by 59% of patients in the standard control group. Sulphonylureas continue to play a critically important role in glucose control and in vascular and renal protection for patients with type 2 diabetes, as demonstrated with gliclazide MR in ADVANCE.

Reasons why UK general practitioners do not initiate antihyperglycaemic therapy in older and younger patients following diagnosis of type 2 diabetes

Q. Zhang[1], K. Jameson[2], S. Meiler[3], M.J. Davies[1], L. Radican[1], A. Sinclair[4];
[1]Global Outcomes Research, Merck, Whitehouse Station, USA, [2]Outcomes Research, MSD, Hoddesdon, United Kingdom, [3]KantarHealth GmbH, München, Germany, [4]University of Bedfordshire, Luton, United Kingdom.

Background and aims: Research has reported benefits for early treatment of type 2 diabetes (T2DM). However, delayed treatment has been found more commonly in older patients. This study compared characteristics of younger and older patients with diagnosed T2DM who were untreated with antihyperglycaemic agents (AHAs) for at least 6 months following diagnosis and assessed physicians' reasons for non-treatment.
Materials and methods: A survey was conducted in Nov 2009-Jan 2010 among 358 UK general practitioners. Physicians provided data from chart review on patients aged ≥18 years were untreated with any AHA for ≥6 months after diagnosis. Each physician also chose reasons for not initiating AHA therapy for their selected patients. Thirty six potential reasons were classified into 4 major categories: mild hyperglycaemia, factors related to AHA therapy, issues with co-morbidities and/or polypharmacy, and patient-related reasons.

All analyses were stratified by patient's age at the time of T2DM diagnosis (younger [<65 years] vs. older [≥65 years]). Group differences were assessed with a t-test for mean, rank test for median and χ^2 test for proportions.
Results: Of the 2,028 patients provided by the physicians, 1,023 were younger (mean age=51 years; mean most recent HbA_{1c}=6.8%; 61% males) and 1,005 were older (mean age=74 years; mean most recent HbA_{1c}=6.8%; 54% males). Compared to younger patients, older patients had a longer duration of T2DM (median 25 vs. 18 months), lower BMI (29 vs. 31 kg/m^2), and a higher prevalence of cardiovascular conditions (18% vs. 5%) and microvascular complications (15% vs. 4%) (all p<0.001). The proportion of patients with most recent HbA_{1c} ≥6.5% (UK treatment target <6.5%) did not differ significantly between older and younger patients (58% vs. 59%, respectively). The most commonly reported reason for not initiating an AHA by physicians was related to mild hyperglycaemia and was not different between groups (86% for older and 88% for younger patients). Compared to younger patients, factors related to AHAs (46% vs. 38%) and issues with co-morbidities/polypharmacy (33% vs. 19%), both including safety-related issues, were more commonly reported reasons for not initiating AHA therapy in older patients (all p<0.001). The reported patient-related reasons were not different between older (41%) and younger (43%) patients.
Conclusion: Among patients who were untreated with an AHA for ≥ 6 months following diagnosis of T2DM, nearly 60% had a most recent HbA_{1c} above the recommended goal <6.5%. Mild hyperglycaemia was the most reported reason by physicians for non-treatment in all patients, regardless of age. AHA-related factors, e.g., "may cause hypoglycaemia", were more frequently reported by physicians as reasons for non-treatment among older patients. Given older patients have higher prevalence of vascular complications, delay in diabetes treatment for this population may have greater health implications than for younger patients.

The likelihood of initiating insulin is increased in UK patients with newly diagnosed type 2 diabetes who received initial monotherapy with sulphonylurea compared with metformin
P. Mavros[1], C. Zhao[1], Q. Zhang[1], S.S. Engel[2];
[1]Global Outcomes Research, Merck Sharp & Dohme, Corp., Whitehouse Station, USA, [2]Merck Research Laboratories, Merck Sharp & Dohme, Corp., Rahway, USA.

Background and aims: Despite initial treatment with a single antihyperglycaemic agent (AHA), the addition of other AHAs including insulin is ultimately required in many patients. This study examined the association of initial oral AHA monotherapy choice with the likelihood of subsequent addition of insulin among patients with newly diagnosed type 2 diabetes (T2DM).
Materials and methods: This retrospective cohort study used a sample from the MediPlus database of general practitioners in the UK. Patients with newly diagnosed T2DM during 1992 to 2008 who were ≥30 years old at the first T2DM diagnosis and who received either metformin (MET) or sulphonylurea (SU) as initial monotherapy in 1992 or beyond were included. The follow-up period lasted to the end of 2008 or the patients' latest data available. The time from initial oral AHA monotherapy (MET or SU) to insulin initiation was estimated based on prescription records. An adjusted Cox proportional hazards regression was conducted to evaluate the likelihood of insulin addition.
Results: Of the 15,926 patients with newly diagnosed T2DM who initiated either MET or SU monotherapy, 65% initiated with MET and 35% with SU. Patients initiated with SU were older at initial monotherapy (mean age 67 vs. 61 years), had lower BMI (mean 28 vs. 33 kg/m^2), and had higher incidence of insulin addition (21% vs. 9%) and shorter time to insulin initiation (median 5,504 vs. 5,613 days) compared to those initiated with MET (all p<0.001). Adjusted for gender, age at and the year of initial monotherapy, BMI, selected co-morbidities, and other medication use, patients started with SU monotherapy were more likely to initiate insulin (adjusted hazard ratio: 1.77 [95% CI: 1.53, 2.06]; p<0.001) than those started with MET.
Conclusion: After adjustment for potential differences in patient profiles which may be associated with beta-cell dysfunction (i.e., lower weight and older age), patients with newly diagnosed T2DM in the UK who started with SU monotherapy tended to receive insulin significantly faster and more often compared with those who started with MET monotherapy.

Time to add-on medication use for patients with type 2 diabetes who failed metformin monotherapy
Y. Qiu[1], A.Z. Fu[2], L. Radican[1];
[1]Merck Sharp & Dohme, Corp., Whitehouse Station, USA, [2]Quantitative Health Sciences, Cleveland Clinic, USA.

Background and aims: Add-on medication regimens are recommended if target glycaemic goals for patients with type 2 diabetes (T2DM) are not achieved or sustained after initial metformin monotherapy. However, it is not clear how long it takes for additional treatment to be used after metformin monotherapy failure in clinical practice. This study was undertaken to address this question.
Materials and methods: The study cohort was selected from a large US electronic medical record database from 1/1/1997 to 12/31/2008. Included subjects had to be aged ≥18 years with a diagnosis of T2DM who had HbA_{1c} ≥7.0% or at least two fasting blood glucose levels of ≥126mg/dL (7 mmol/L). Treatment failure was defined as HbA_{1c} ≥7% (index date) after metformin monotherapy for at least 6 months. Baseline data were extracted during 1 year prior to the index date. Time to add-on medication use was the time between the index date to the first add-on medication use during follow-up period and was evaluated for the overall cohort and for three index HbA_{1c} subgroups: 7-8%, 8-9%, and >9%. A Cox proportional hazard model was employed to determine baseline clinical and demographic characteristics associated with shorter time to add-on medication use.
Results: There were 12,566 patients meeting the inclusion criteria; 8656, 2175 and 1735 had index HbA_{1c} 7-8%, 8-9%, and >9%, respectively. The overall mean (SD) age was 63 (12) years and 51% were female. The median time to add-on medication use was 15.7 months overall and 17.0, 13.9 and 11.3 months for patients with index HbA_{1c} 7-8%, 8-9%, and >9%, respectively. Higher index HbA_{1c}, greater body mass index, higher Charlson comorbidity index, younger age, males, lower LDL-cholesterol were significantly associated with shorter time to add-on medication use (all p<0.05).
Conclusion: In clinical practice in the US, it takes nearly 16 months for T2DM patients with sub-optimal glycemic level after initial metformin monotherapy to receive additional antihyperglycaemic therapies. There is room for improvement through disease management so that patients who fail metformin monotherapy and are eligible and appropriate for treatment intensification, receive add-on therapy sooner rather than later.

Is three months sufficient to assess HbA_{1c} reduction in high-baseline patients? An analysis of HbA_{1c} time course after initiation of metformin alone or in combination with sitagliptin
S.S. Engel, H. Katzeff, H. Wang, Q. Dong, R.B. Langdon, D.E. Williams-Herman, K.D. Kaufman, B. Goldstein;
Merck Research Laboratories, Rahway, USA.

Background and aims: The ADA/EASD consensus algorithm for treatment of type 2 diabetes recommends that antihyperglycemic (AHA) medications be added if target A1C levels are not achieved within 2-3 months. We examined whether this timeframe is adequate to assess the full response to a new course of therapy.
Materials and methods: The time course of change in A1C was analyzed in data pooled from 2 randomized, double-blind, multicenter studies of drug-naïve patients treated for 30-31 weeks with metformin (MET) 2000 mg/day (uptitrated during Weeks 0-4) as monotherapy (N=803) or in combination with sitagliptin 100 mg/day (SITA/MET) (N=807). The analysis determined each patient's maximum A1C reduction ($\Delta A1C_{MAX}$) and the cumulative proportions of patients first achieving 95% of $\Delta A1C_{MAX}$ at Weeks 6, 12, 18, and 30. It included all patients who completed treatment without rescue (n=514 and 538 in the MET and SITA/MET groups, respectively) and 3 subgroups composed of patients with baseline A1C ≤8.0% (n=253), >8.0-≤9.5% (n=376), and >9.5 % (n=423).
Results: Mean $\Delta A1C_{MAX}$ was −2.2% and −2.6% in the overall MET and SITA/MET treatment groups. Both groups had significant reductions in A1C at the earliest time point measured. At Week 12, however, only 32.7% and 29.9% of patients on MET and SITA/MET, respectively, had reached 95% of $\Delta A1C_{MAX}$; at Week 18, the proportions were 71.4% and 73.0%, respectively. Evaluation after 12 weeks appeared to be especially premature in high-baseline A1C patients who received SITA/MET and had the greatest reductions in A1C

during treatment. Among SITA/MET-treated patients in the subgroup with baseline A1C>9.5% (n=223; mean $\Delta A1C_{MAX}$ = −3.7%), only 22.9% reached 95% of $\Delta A1C_{MAX}$ by Week 12, compared with 40.7% in the baseline A1C≤8% subgroup (n=123; mean $\Delta A1C_{MAX}$ = −1.2%).
Conclusion: This analysis found that full A1C-lowering efficacy of AHA medications was not demonstrated in most patients after only 3 months of treatment. Further, these findings suggest that patients with higher baseline A1C levels may require longer periods of time to reach a steady-state A1C level.

912

Discontinuing SU and initiating insulin detemir + sitagliptin: improved efficacy and similar safety vs. adding sitagliptin to a prior SU regimen. A TRANSITION™ trial subanalysis

K. Rašlová[1], J. Liutkis[2], T.V. Skjøth[3], J. Råstam[3], P.A. Hollander[4];
[1]Metabolicke Centrum, Bratislava, Slovakia, [2]Vascular Risk Modification Clinic, Cambridge, Canada, [3]Novo Nordisk A/S, Copenhagen, Denmark, [4]Baylor University Medical Center, Dallas, USA.

Background: Once-daily insulin detemir (IDet) is often prescribed for patients with T2D as add-on to OAD. IDet has not previously been evaluated in combination with a newer class of OAD, dipeptidyl peptidase-4 (DPP-4) inhibitors, which reduce enzymatic degradation of the incretin glucagon-like peptide-1 (GLP-1) and thereby enhance glucose-dependent insulin secretion. In this randomized, open-label, parallel group, 26-week trial of insulin-naïve T2D patients who were poorly controlled by a previous regimen with metformin (Met) ± sulphonylurea (SU) or other OADs, IDet was administered in combination with the DPP-4 inhibitor sitagliptin (SITA) and Met with prior SU, if any, discontinued. This was compared for efficacy and safety against SITA + Met in combination with the subjects' prior SU regimens, if any, continued. This is a sub-group analysis which reports outcomes only for patients with pre-trial SU treatment regimens.
Materials and methods: This subgroup analysis is comprised of the 75% of subjects (*n*=80) in the IDet + SITA group and the 77% of subjects (*n*=85) in the SITA ± SU group who had a pre-trial SU regimen (SITA + SU). Treatment groups compared IDet + SITA as add-on to Met, coupled with discontinuation of prior SU therapy, vs. SITA as add-on to Met + pre-trial SU. Results described herein are after 26 weeks' treatment with once-daily IDet + SITA (100 mg QD) + Met (≥1000 mg) (IDet/SITA) with discontinuation of pre-trial SU, vs. SITA + Met + SU (SU/SITA) (at each subject's pretrial SU dose). A normal linear regression model was used to analyze HbA_{1c}, FPG, body weight and BMI.
Results: Observed baseline A1c was 8.46 and 8.58%, with final mean estimated A1c of 7.23 and 7.63% for the IDet/SITA and SU/SITA groups, respectively. Estimated reductions in A1c, after baseline adjustment for covariates, were 1.29 and 0.88% (est. mean diff. = -0.40%; 95% CI = [-0.66; -0.15], *p*=0.002), for IDet/SITA and SU/SITA, respectively. FPG fell to 6.20 and 8.53 mmol/L from observed baselines of 9.61 vs. 9.79 mmol/L for the IDet/SITA and SU/SITA groups, respectively, with estimated reductions of 3.51 vs. 1.18 mmol/L (est. mean diff. = -2.34 mmol/L, 95% CI = [-3.00;-1.68], *p*<0.001). Body weight and BMI decreased in both subgroup treatment arms with no significant differences between groups (-1.10 vs. -1.42 kg, and -0.40 vs. -0.52 kg/m^2, *p*=NS, IDet/SITA vs. SU/SITA, respectively). No major hypoglycemia was reported. Minor hypoglycemia (PG <3.1 mmol/L) was low in both arms (0.58 and 0.70 estimated events/patient-year, Adjusted Rate Ratio = 0.84 [95% CI: 0.27, 2.65]; *p*=NS, IDet/SITA vs. SU/SITA, respectively). Final insulin dose was 0.59 U/kg at trial end.
Conclusion: The results of this subgroup analysis - improved A1c, FPG, low hypoglycemia and modest decreases in body weight and BMI in both arms - supports substitution of IDet/SITA for SU, or addition of SITA to SU + Met. Better glycemic control (i.e. lower A1c and FPG) was achieved for IDet/SITA compared to the SU/SITA arm among these pre-trial SU users with low incidence of hypoglycemia. Therefore, discontinuation of SU and substitution of once-daily IDet in combination with a DPP-4 inhibitor, SITA and Met is a safe and more effective treatment option for insulin-naïve T2D patients, compared to adding SITA to an existing SU and Met regimen.

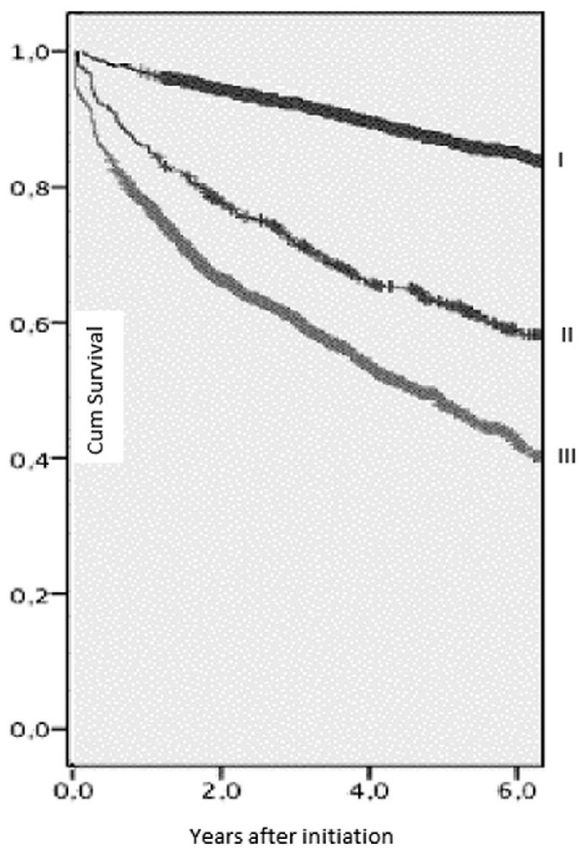
Long-term patterns of statin therapy in patients with type 2 diabetes mellitus compared to long-term oral anti-diabetic medication patterns

E.J.F. Lamberts[1], M.L. Bouvy[1], P.C. Souverein[1], G. Nijpels[2], L.M.C. Welschen[2], J.G. Hugtenburg[2], J.M. Dekker[2];
[1]Division of Pharmacoepidemiology and Pharmacotherapy, Utrecht Institute for Pharmaceutical Sciences Faculty of Science, [2]EMGO, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Statins are effective in the prevention of cardiovascular disease in type 2 diabetes mellitus. However studies on long-term use of statins among type 2 diabetes mellitus patients are scarce. The aim of this study was to describe long-term patterns of statin use among patients with type 2 diabetes mellitus and compare discontinuation of statins and oral antidiabetics.
Methods: A cohort study among 2072 patients with type 2 diabetes mellitus who initiated treatment with statins between 1999 and 2007. Drug dispensing data were extracted from 17 community pharmacies in a geographically well-defined region in The Netherlands. Patients were classified as using statins before (prevalent users) or after (incident users) the initiation of oral antidiabetics. Patients were considered to have discontinued statin therapy when an interval of 180 days or more occurred between the theoretical end date of a statin prescription and a subsequent statin prescription. This was done in the same way for oral antidiabetics in order to compare discontinuation between the drug groups.
Results: The proportion of patients with type 2 diabetes mellitus using statins increased between 1999 and 2007. Discontinuation rates for statins were higher compared to discontinuation of oral antidiabetic drugs (52.1 vs.15.0%). Moreover, incident statin users were more likely to discontinue statin therapy compared to prevalent statin users (62.8 vs. 48.2%).
Conclusions: Although statins are increasingly prescribed to patients with type 2 diabetes mellitus, discontinuation of statins is high compared to discontinuation of antidiabetics. This could result in suboptimal therapeutic outcomes for patients with type 2 diabetes mellitus.



Long-term continuation of statins and oral anti-diabetic drugs. Shown for anti-diabetics (I), prevalent statin users (II) and incident statin users (III). (Log Rank p < 0.0001)

PS 84 "Metabolic syndrome": definition and management

914

Remission of the metabolic syndrome three years after screening for increased waist circumference

C. den Engelsen, M.C. Busser, M. van den Donk, K.J. Gorter, P.L. Salomé, G.E.H. Rutten;
Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands.

Background and aims: Screening for cardiovascular risk factors and diabetes among overweight and obese individuals might be an attractive option with potential health benefits. In 2006, such a screening in primary care was performed to detect individuals with the metabolic syndrome (MetS) by letting them measure their waist circumference at home as a first step. Among individuals aged 20-70 years, previously not known with hypertension, diabetes or dyslipidemia and selected by means of a self-measured increased waist circumference, 473 new MetS cases were detected. They were advised to contact their general practitioner. However, screening of individuals with a high cardiovascular risk is only meaningful if adequate subsequent and effective action is undertaken. The aim of this study was to assess the remission of the MetS three years after screening followed by usual care in general practice.
Materials and methods: 432 individuals with screen-detected MetS (those of the original group of 473 patients that still visited the same general practice) were invited for follow-up measurements, which included a physical examination and laboratory tests. The MetS was defined according to the NCEP ATP III criteria. We also invited a random selection of 280 individuals who had an increased self-measured waist circumference during screening, but did not meet the MetS criteria at that time.
Results: The overall response rate was 84%. 63% of the responders indicated to be interested in follow-up measurements (the 'participants'). 197 individuals with MetS at screening and 179 individuals without MetS at screening underwent all follow-up measurements. A significant improvement in all MetS components, except for glucose, was seen in the group with screen-detected MetS (table). The remission rate was 53%. The only significant changes in the group without MetS in 2006 were a decrease in diastolic blood pressure, an increase in triglyceride level and a decrease in HDL-cholesterol level in women. 15% of the participants in this group developed the MetS at follow-up. Non-participants and participants were comparable in age, gender and mean level of MetS components in 2006. The 16% non-responders with screen-detected MetS were significantly younger than the responders (both participants and non-participants) with screen detected MetS.
Conclusion: Screening for MetS among overweight and obese individuals, followed by care as usual, leads to significant improvements in all MetS components and a remission rate of 53% among the individuals with screen-detected MetS. This might be an attractive option with potential health benefits.

Mean levels (SD) of MetS components, BMI and weight in 2006 (screening) and 2009 (follow-up)

	2006	2009	P-value
BMI (kg/m2)	30.2 (3.6)	29.3 (4.1)	<0.001
Weight (kg)	93.2 (15.2)	90.8 (16.1)	<0.001
Waist circumference men (cm)	109.9 (7.4)	106.1 (10.0)	<0.001
Waist circumference women (cm)	99.6 (8.8)	96.1 (10.7)	<0.001
Systolic blood pressure (mmHg)	143.7 (15.0)	135.5 (13.5)	<0.001
Diastolic blood pressure (mmHg)	88.0 (7.5)	82.4 (7.7)	<0.001
Triglycerides (mmol/L)	2.2 (1.1)	1.9 (0.9)	0.001
HDL-cholesterol men(mmol/L)	1.1 (0.3)	1.2 (0.3)	<0.001
HDL-cholesterol women (mmol/L)	1.3 (0.3)	1.4 (0.3)	<0.001
Fasting blood glucose (mmol/L)	5.3 (1.2)	5.4 (0.8)	0.02

Improving cardiometabolic risk by lifestyle modification in viscerally obese men: is weight loss the best therapeutic target?

A.-L. Borel[1], N. Alméras[1], J. Bergeron[2], A. Tremblay[1,3], P. Poirier[1,4], J.-P. Després[1,3];
[1]Centre de recherche de l'Institut universitaire de cardiologie et de pneumologie de Québec, [2]Centre de recherche du Centre hospitalier de l'Université Laval, [3]Faculté de médecine, Département de médecine sociale et préventive, Division de kinésiologie, [4]Faculté de pharmacie, Quebec, Canada.

Background and aims: Visceral obesity is associated with a diabetogenic/atherogenic cardiometabolic risk (CMR) profile. Most intervention studies aiming to reduce CMR have used magnitude of weight loss as their main outcome measure. The present work compared the CMR profile response to a one-year healthy eating/physical activity lifestyle modification program of high risk viscerally obese men (waist girth ≥ 90 cm, triglycerides ≥ 1.69 mmol/L and/or HDL cholesterol < 1.03 mmol/L) classified into two groups according to both weight loss and loss of visceral adipose tissue (VAT).
Materials and methods: From the 144 viscerally obese men who participated in the study (age 47.5 ± 9.0 years, waist girth 107.8 ± 8.5 cm, triglycerides 2.52 ± 0.89 mmol/L, HDL-cholesterol 0.95 ± 0.16 mmol/L), 109 completed the first year of intervention. In the present analysis, we examined the relationship between weight loss and loss of VAT in the subgroup of 100 men who lost both weight and VAT. Body weight, body composition and fat distribution were assessed by anthropometry and DEXA/computed tomography. Cardiorespiratory fitness and fasting lipoprotein/lipid profile were assessed, and an oral glucose tolerance test (75 g) was performed. The regression line between weight loss and loss of VAT was used to define two groups of men, below and above the regression line (figure). Group 1 and group 2 were defined as men having lost more (group 1: 10 ± 4 %) or less (group 2: 6 ± 4 %) body weight than predicted by the regression line.
Results: At baseline, group 1 presented higher body weight and subcutaneous adipose tissue (SAT) volume than group 2 (97 ± 13 vs. 92 ± 9 kg and 1886 ± 558 vs. 1585 ± 476 cm^3, for group 1 and 2 respectively, $p < 0.05$), but lower VAT volume (1843 ± 493 vs. 2043 ± 431 cm^3, respectively, $p = 0.03$). After the one-year intervention, group 1 had lost more weight and SAT than group 2 (-9.2 ± 4.1 vs. -5.2 ± 3.9 kg and -446 ± 284 vs. -245 ± 195 cm^3, respectively, $p < 0.0001$). However, loss of VAT was similar between the two groups. Finally, despite greater absolute and relative losses of body weight and body fat in group 1 than 2, both groups showed essentially similar improvements in their CMR profile.
Conclusion: Provided that loss of visceral AT is similar, magnitude of weight loss does not appear to have any additional effects on the response of the CMR profile to a one-year lifestyle modification program. Therefore, our results suggest that magnitude of VAT loss may be a better therapeutic target than weight loss.

Optimal serum alanine aminotransferase cutoffs for the metabolic syndrome in Chinese

M. Xia[1], H. Yan[1], H. Bian[1], B. Pan[2], X. Gao[1];
[1]Endocrinology, [2]Laboratory Medicine, Zhongshan Hospital, Shanghai, China.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most frequent liver disease in China and western countries. It has been demonstrated that NAFLD was significantly correlated with all components of the metabolic syndrome (MetS), and could independently predict the risks of type 2 diabetes and coronary vascular disease (CVD). Serum alanine aminotransferase(ALT) concentration is the most commonly measured variable for assessment of liver disease. However, the current ALT upper limit (40 IU/L) often fails to identify patients with MetS and potential hepatic fat infiltration, thus underestimating the risks of type 2 diabetes and CVD. It has been recently recommended that the normal upper limit for ALT should be revised to 30 IU/L for men and 19 IU/L for women to identify NAFLD or chronic HCV infection in western countries. However, the optimal ALT cutoffs for metabolic syndrome in Chinese communities were poorly studied. The aim of the present study was to determine the optimal cutoffs for ALT linking to the risk of the MetS in Chinese subjects.
Materials and methods: The study population consisted of 440 subjects (242 male and 198 female) aged from 18 to 80 years recruited from the local community and outpatient department of endocrinology, Shanghai Zhongshan Hospital. Participants with hepatitis B or C, excessive alcohol intake and other hepatic disease were excluded. A standard interview, anthropometrics (height, weight, waist, hip circumference and blood pressure), Laboratory parameters (ALT, serum lipid, fasting plasma glucose, 2 h postload plasma glucose) were conducted for each participant. Metabolic syndrome was defined according to the International Diabetes Federation criteria. Statistical analyses were performed with SPSS for windows 15.0. All reported p values were two-tailed and *p*-values less than 0.05 were considered statistically significant. Univariate analysis of variance was used to detect the association between ALT level and all MetS components. Receive operating characteristic (ROC) curve analyses were utilized to determine the appropriate cutoffs of ALT for identifying individuals with MetS.
Results: In 242 men there were 97(40.1%) with MetS, and in 198 women there were 89(55.1%) with MetS. The frequency of MetS was elevated with increased ALT level in both male and female participants. Stratified according to sex, Univariate analysis showed ALT level was associated with waist circumference, serum cholesterol and LDL-c in female, but only associated with waist circumference in male. The optimal cutoffs were 36IU/L in male and 19IU/L in female for ALT to identify MetS patients. Compared with the current ALT upper limit, the revised ALT cutoffs were more sensitive and efficacious in identifying MetS, especially in women (Table 1).
Conclusion: The optimal cutoffs of ALT for MetS are 36IU/L for men and 19IU/L for women in Chinese. The current used ALT upper limit (40 IU/L) could underestimate MetS accompanied by NAFLD, especially in women.

Table 1 Sensitivity and specificity of ALT to determine subjects with MetS based on the IDF definition

	Female(n=198)		Male(n=242)	
	Optimal ALT cutoff	Current ALT cutoff	Optimal ALT cutoff	Current ALT cutoff
Area under curve	0.673		0.681	
cutoff value	19U/L	40U/L	36U/L	40U/L
Sensitivity	0.764	0.371	0.691	0.65
Specificity	0.587	0.798	0.646	0.667

Two major patterns of dynamics in adipokine serum concentrations over 2 years of dietary weight-loss intervention

M. Blüher[1], A. Rudich[2], N. Klöting[1], R. Golan[3], E. Rubin[3], D. Schwarzfuchs[4], M. Fiedler[1], Y. Gepner[3], O. Tangi[3], M. Stampfer[5], J. Thiery[1], M. Stumvoll[1], I. Shai[3];
[1]Department of Medicine, University of Leipzig, Germany, [2]The Department of Clinical Biochemistry, Ben-Gurion University, Beer-Sheva, Israel, [3]S. Daniel Abraham Center for Health and Nutrition, Ben-Gurion University, Beer-Sheva, Israel, [4]Nuclear Research Center Negev, Nuclear Research Center Negev, Dimona, Israel, [5]Brigham and Women's Hospital, Harvard School of Public Health, Boston USA.

Background and aims: During dietary interventions, adipokines' serum concentrations may be affected by changes in adipose tissue mass and/or by direct effects of healthier dieting. However, which are the adipokines that follow hormones and lipid parameters that mainly reflect weight changes, versus those that are primarily affected by the dietary change that could persist beyond weight change is largely unknown.
Materials and methods: In the 2-year Dietary Intervention Randomized Controlled Trial (DIRECT) among patients with type 2 diabetes (T2D, n=45) and non-diabetics (n=277), which have been randomly assigned to one of three diets: low-fat, Mediterranean, or low-carbohydrate, we analyzed the dynamics in circulating levels of adipokines, as well as serum concentrations of traditional biomarkers, and their association with 2-year changes in homeostasis model assessment-insulin resistance (HOMA-IR) and carotid artery intima-media thickness (IMT).
Results: Both qualitative analysis of the changes in biomarker levels at baseline, 6 and 24 months of intervention, and utilizing a non-biased mathematical modeling approach, revealed 2 major patterns of dynamics. Pattern A included biomarkers whose dynamics closely reflect changes in body weight, which exhibited a rapid decline (0-6 months) followed by weight stabilization or regain (7-24 months). This pattern included fasting circulating levels of insulin, triglycerides (TG), leptin, chemerin, monocyte chemoattractant protein-1 (MCP-1), and retinol binding protein-4 (RBP4). Pattern B consisted of biomarkers that displayed a continuing, cumulative increase or decrease throughout the 24 months of dietary intervention, despite the partial regain in mean body weight. This group included high molecular weight (HMW) adiponectin, HDL-cholesterol, CRP, fetuin-A, progranulin, and vaspin. Patterns A and B were similar among patients with T2D and non-diabetics. In models adjusted for age, sex and assigned diet group, a greater decline in either chemerin (beta=0.136, p=0.034) or leptin (beta=0.250, p<0.001) within the first 6 months of intervention were associated with lower levels of HOMA-IR at 24 months. In multivariate models adjusted for age, sex, assigned diet group, and 24 months changes in weight, chemerin, progranulin and MCP-1, greater decrease in fetuin-A predicted a larger decline in IMT of the carotid artery by the end of the 2 years intervention (beta = 0.201, p=0.040).
Conclusion: During a 2-year dietary intervention, leptin, chemerin, MCP-1 and RBP4 corresponded mainly to body weight, similar to serum insulin and TG levels. In contrast, HMW adiponectin, fetuin-A, progranulin, and vaspin exhibited cumulative improvement despite partial weight regain, similar to the changes in HDL-cholesterol and CRP. The two patterns underscore weight -associated versus healthy diet -induced beneficial effects beyond weight loss, and suggest a potential predictive value for clinically-relevant metabolic and cardiovascular endpoints.

Effect of dietary fat modification on insulin secretion in subjects with the metabolic syndrome

H.L. Gulseth[1,2], I.M.F. Gjelstad[1,2], J.A. Lovegrove[3], C. Defoort[4], E.E. Blaak[5], J. Lopez-Miranda[6], A. Dembinska-Kiec[7], U. Risérus[8], H.M. Roche[9], C.A. Drevon[2], K.I. Birkeland[1];
[1]Department of Endocrinology, Oslo University Hospital, Norway, [2]Department of Nutrition, University of Oslo, Norway, [3]University of Reading, Reading, United Kingdom, [4]INSERM, Marseille, France, [5]Maastricht University, Netherlands, [6]University of Cordoba, Spain, [7]Jagiellonian Medical College, Krakow, Poland, [8]Uppsala University, Sweden, [9]University College Dublin, Ireland.

Background and aims: Both β-cell dysfunction and insulin resistance contribute to the development of type 2 diabetes. Dietary fat may have beneficial effects on insulin sensitivity, but the effect on insulin secretion is less clear. We investigated the effect of dietary fat modification on insulin secretion in European subjects with the metabolic syndrome.

Material and methods: In a 12 weeks parallel, randomized controlled dietary intervention trial (LIPGENE) 486 subjects were randomly assigned to isoenergetic diets: High fat (38 energy%) diets rich in saturated fat (HSFA) or monounsaturated fat (HMUFA) or low-fat (28 energy%), high complex carbohydrate diets with (LFHCC n-3) and without (LFHCC-control) 1.2 g/day of n-3 PUFA. The β-cell function was measured as acute insulin response (AIRg) and disposition index (DI), modeled from intravenous glucose tolerance test (IVGTT). The mean age was 54.4 ± 9.0 years, BMI was 32.3 ± 4.1 kg/m2 and 45% were males.
Results: There was no overall effect on AIRg and DI of the dietary intervention, but there were significant diet*fasting category of glucose interactions for AIRg (p=0.021) and DI (p=0.001). In subjects with normal fasting glucose and preserved first phase insulin secretion the effects of dietary intervention were significantly different between the HMUFA and the HSFA diets for both AIRg (p=0.015) and DI (p=0.010). There were no differences between the LFHCC diets.
Conclusion: The effects of dietary fat modification on β-cell function were minor in the total cohort, but in normoglycemic subjects the HMUFA diet improved AIRg and DI as compared to the HSFA diet.

Defining waist circumference cut points for South Asians in the United Kingdom using measures of dysglycaemia

L.J. Gray[1], T. Yates[2], E.M. Brady[3], M.J. Davies[2], D.R. Webb[2], N. Sattar[4], K. Khunti[1];
[1]Department of Health Sciences, University of Leicester, , [2]Department of Cardiovascular Sciences, University of Leicester, , [3]Department of Diabetes and Endocrinology, University Hospitals of Leicester, [4]BHF Glasgow Cardiovascular Research Centre, University of Glasgow, United Kingdom.

Background and aims: To determine waist circumference cut-points in South Asians giving equivalent levels of dysglycaemia as in white Europeans with waist levels equivalent to obese BMI cut-points.
Materials and methods: 4688 white Europeans and 1353 South Asians aged 40- 75 years were screened for Type 2 diabetes. Regression models for fasting glucose, two-hour post-challenge glucose, HbA1c and a glucose factor (derived using principal components from the three glucose parameters), adjusted for centred age and stratified by sex, were used to identify waist circumference cut points in South Asians that correspond to glycaemic values at the recommended 'obese' waist circumferences of 102cm for males and 88cm for females in white Europeans.
Results: For South Asians the derived waist circumference cut points were substantially lower than for white European males and females across all glucose parameters. An overall glucose factor score at a cut point of 102cm in white Europeans was met by South Asian males at a waist circumference of 84cm. Similarly, a cut point of 88cm for white European females was equivalent to cut point 69cm for South Asian females. Here 7.5% of South Asian males have a waist circumference ≤84cm and 4.2% of females have a waist circumference ≤69cm.
Conclusion: Remarkably low cut points for defining very high waist circumferences for males and females are needed in South Asians for detecting equivalent levels of dysglycaemia as in obese white Europeans. Although the IDF already accepts a lower cut point for South Asian males (90cm), the even lower cut points suggested herein suggest that South Asian people should be considered at high risk of diabetes irrespective of waist circumference measurements.

Assessing cardiometabolic risk among shift workers

G. Jermendy[1], T. Hidvégi[2], J. Osztovits[1], J. Nadas[1], I. Hegyi[3], I. Vasas[3];
[1]3rd Medical Department, Bajcsy-Zsilinszky Hospital, Budapest, [2]Petz Hospital, Győr, [3]Kardirex Health Center, Győr, Hungary.

Background and aims: The term of cardiometabolic risk includes a cluster of cardiovascular risks beyond the metabolic syndrome. Shift workers, possibly due to impairment in circadian biological rhythm, may be at higher cardiometabolic risk. In order to assess cardiometabolic risk in shift workers, a cross-sectional study was performed among active workers (aged 25-66 years, with a minimal shift working experience of 5 years).
Materials and methods: We investigated 481 workers (121 male, 360 female) in our study, most of them were employees in light industry (58.2%) or in public service (23.9%). At enrolment, past medical history was recorded and anthropometric measurements and physical examination were performed in each subject. Validated questionnaires were used to characterize daily activity, eating and smoking habits. Fasting venous blood sample was taken for measuring laboratory parameters. Data from shift workers (n=234, 54 men and 180 women, age 43.9±8.1 years) were compared to those of day workers (n=247, 67 men and 180 women, age: 42.8±8.5 years).
Results: Weight (76.6±16.1 *vs* 73.9±17.6 kg; p<0.05), BMI index (27.5±5.3 *vs* 26.0±4.9 kg/m^2; p<0.01), systolic blood pressure (123±19 *vs* 119±16 mmHg, p<0.01), the prevalence rate of diabetes (4.3 *vs* 1.2 %; p<0.05) and cardiovascular diseases (3.8 *vs* 0.8 %; p<0.05) in the past medical history were higher in shift workers as compared to day workers. In addition, proportion of subjects with regular physical activity in leisure time were lower (20.6 *vs* 38.7 %; p<0.001) and that of current smokers were higher (35.0 % *vs* 19.5 %; p<0.001) in shift workers than in day workers. As for laboratory findings, HDL-cholesterol level was lower in female shift workers than in female day workers (1.56±0.32 *vs* 1.68±0,36 mmol/l; p<0.01).
Conclusion: These data indicate that middle-aged, active shift workers, as compared to day workers, are at higher cardiometabolic risk. Thus, our study highlights the importance of measures for preventing cardiovascular diseases in shift workers.

Immunological and cardiometabolic risk scores in the prediction of incident type 2 diabetes and coronary events: MONICA/KORA Augsburg case-cohort study

C. Herder[1], J. Baumert[2], A. Zierer[2], M. Roden[1,3], C. Meisinger[2], W. Koenig[4], B. Thorand[2];
[1]Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, [2]Helmholtz Zentrum München, Neuherberg, [3]University Hospital Düsseldorf, [4]University of Ulm Medical Center, Germany.

Background and aims: Systemic concentrations of acute-phase proteins, cytokines, chemokines and soluble adhesion molecules are associated with the risk of type 2 diabetes and coronary events. The association of each of these biomarkers alone with incident disease is too weak for the prediction of outcomes, but the predictive value of combinations of multiple inflammation-related biomarkers is still unclear. This study aims to address the following questions: (i) what is the predictive value of inflammation-related biomarkers for incident type 2 diabetes and coronary events, (ii) are these predictive values comparable with the those of established biomarkers of cardiometabolic risk, and (iii) can the predictive value be improved by combining both sets of risk factors?
Materials and methods: The study investigates inflammation-related biomarkers (measured in non-fasting serum samples) and additional cardiometabolic risk factors in a prospective case-cohort study within the population-based MONICA/KORA Augsburg cohort. Analyses with the endpoint type 2 diabetes are based on 436 individuals with and 1413 individuals without incident type 2 diabetes. Analyses for coronary events are based on 314 individuals with and 1662 individuals without incident coronary events. The follow-up was 10±5 years. Receiver operator characteristic (ROC) analyses were used to calculate areas under the ROC curve (AROC) for different sets

of risk factors for both incident type 2 diabetes and incident coronary events: (a) basic model: adjusted for age, sex, and survey; (b): immunological model: factors from (a) plus CRP, IL-6, IL-18, MIF, TGF-beta1, MCP-1, IL-8, IP-10, RANTES, adiponectin, leptin, sE-selectin, sICAM-1; (c) cardiometabolic model: factors from (a) plus BMI, systolic blood pressure, total cholesterol/HDL cholesterol ratio, parental history of diabetes or myocardial infarction (according to the respective endpoint), smoking, alcohol, physical activity; (d) full model: combination of risk factors in (b) and (c).
Results: For the prediction of type 2 diabetes, the AROC for the basic model was 0.733. Addition of either inflammation-related biomarkers (as continuous variables) or cardiometabolic risk factors resulted in an increase to 0.803 in both models. A combination of all risk factors predicted type 2 diabetes with an AROC of 0.845. For the prediction of coronary events, the basic model had a higher predictive value (AROC 0.802), whereas the addition of inflammation-related or cardiometabolic risk factors led to less pronounced increases (AROC 0.825 and 0.836). The combination of all risk factors resulted in a similar predictive value as for type 2 diabetes (AROC 0.849).
Conclusion: The addition of multiple inflammation-related biomarkers to a basic prediction model and to a model including cardiometabolic risk factors increased the AROC in the prediction of type 2 diabetes and coronary events, although the increase was less pronounced for the latter endpoint. As limitation, it is important to note that the results were based on non-fasting blood samples and cannot be extrapolated to different study settings with more complete assessment of diabetes risk factors including glucose, insulin and HbA1c measurements.

Significant type 2 diabetes incidence reduction in high risk participants, after three years of an intensive lifestyle intervention in primary care (DE-PLAN-CAT)
X. Cos[1], B. Costa[1], F. Barrio[1], J.J. Cabré[1], S. Sarret[1], M. Cot[1], X. Mundet[1], F. Pujol[1], J. Caula[1], T. Mur[1], J.L. Piñol[1], J. Basora[1], B. Bolíbar[1], C. Castell[2], y el Grupo de Investigación DE-PLAN-CAT.;
[1]IDIAP Jordi Gol, [2]Public Health Department, Barcelona, Spain.

Background and aims: Many Lifestyle interventions have demonstrated their efficacy preventing Type 2 Diabetes although none of them have shown their benefits into real clinical practice. Public health strategy on type2 diabetes prevention in primary health care. The European coordinated project DE-PLAN (*Diabetes in Europe-Prevention using Lifestyle, Physical Activity and Nutritional intervention*) evaluates its effectiveness in Primary Health Care.
Materials and methods: Public health strategy on type2 diabetes prevention in primary health care. Two-step multicentre cohort study: cross-over period (1y-screening) plus a follow-up period (3y-preventive intervention). In Catalonia (DE-PLAN-CAT) has 18 participating centres, more than 150 professionals (GP+nurses) and a representative randomized population based sample between 45-75 yo. Randomized non-invasive diabetes screening program by means of the FINDRISC score comparing with the oral glucose tolerance test (OGTT). All those high risk participants, without Diabetes, received a lifestyle intervention (self-acting informative intervention or intensive). Both groups were followed by "usual care" (self administered group) or by periodically motivation reinforcement. We performed an OGTT after 3 year of the intervention (An OGTT was yearly performed).
Results: A total of 2547 non-diabetic subjects > 45 y were contacted with a 80.6% positive response rate (n=2054). Of them 552 (26.9%) had high diabetes risk and 251 (45.5%) type 2 prediabetes. 210 (38%) were allotted to self-acting informative intervention and 342 (62%) to intensive lifestyle intervention. No differences in risk factor profile or in glycaemic status were detected. Mean annual drop-out rate was 11.4%, statistically higher in the informative group (14,4% / 9,6%; p<0,001). First year (n=476), 37 participants (7.8%) developed Diabetes, finishing the study. Second year (n=383) were diagnosed 32 new cases (8.4 %) and 21 (7.2%) in the third year (n=293). Cumulated diabetes incidence was 24.9%, 32,8% self-acting group vs 21% in the intensive intervention (p<0,01) [RRR 36%]. Progression rates (normality to prediabetes or diabetes and prediabetes to diabetes) were 40.3% and 31.7% (RR=21,3%). Regression rates (prediabetes to normality) were 5.9% and 13.6%, respectively (relative increase =130,5%).
Conclusion: Lifestyle intensive intervention has reduced significantly Type 2 Diabetes incidence, compared with a self-acting informative, in the Spanish Primary Health Care usual practice.

Prenatal environmental exposures that may influence beta cell function or insulin sensitivity in middle age
H.S. Kahn[1], A.D. Stein[2], L.H. Lumey[3];
[1]Division of Diabetes Translation, Natl Ctr for Chronic Dis Prevn & Health Promotion, Atlanta, [2]Hubert Department of Global Health, Emory University, Atlanta, , [3]Epidemiology, Columbia University, New York, USA.

Background and aims: Patterns of fetal and childhood growth are associated with subsequent diabetes, but the underlying mechanisms remain unclear. Few studies have associated the early gestational environment with postnatal physiologic impairments to normal glucose metabolism. Fingerprints are permanently fixed in the first half of pregnancy, and increased values of a marker that contrasts fingerprint ridge counts between the thumbs and fifth fingers (Md15) have been linked to type 2 diabetes. Fingerprint Md15 has been associated also with seasonal features of the early prenatal environment. We studied adults metabolically to explore mechanisms explaining prenatal influences on insulin physiology in later life.
Materials and methods: Among 763 adults without known diabetes from the Dutch Hunger Winter Families Study we tested the associations of Md15 with homeostatic-assessment indices of pancreatic beta-cell function (HOMA-b) and insulin sensitivity (QUICKI). For either outcome index, linear regression analyses included terms for Md15 tertiles and for maternal history of diabetes as reported by each participant. All models were corrected for sibling pairs and adjusted for age, sex, and gestational and periconceptional famine exposures.
Results: Fingerprint Md15 was inversely associated with HOMA-b (p<0.05 for linear trend) but not with QUICKI. In contrast, a maternal history of diabetes was associated with decreased QUICKI (p<0.001) but not with HOMA-b. Paternal history of diabetes was not associated significantly with either index. Birth weight (available for 520 participants) was positively associated with increased QUICKI (p<0.05 for linear trend across tertiles) but not with HOMA-b.
Conclusion: Since Md15 describes variation in the anterior-posterior growth gradient of the early fetal hand, it is noteworthy that this permanent fingerprint characteristic is associated also with beta-cell function in later life. This finding appears consistent with rodent data on the role played by hedgehog signaling proteins in development of the fetal pancreas as well as the fetal forelimb. Research into the environmental circumstances associated with morphological features in the hand may suggest prenatal strategies for optimizing beta-cell function in adult life.

Seasonal variation of type 1 diabetes incidence in childhood in Germany

J. Rosenbauer[1], C. Bächle[2], A. Stahl[2], R. Holl[3], M. Grabert[3], G. Giani[2], in cooperation with the German Pediatric Surveillance Unit and the DPV-Science Initiative;
[1]Institute of Biometrics and Epidemiology, German Diabetes Centre, Leibniz Institute at Duesseldorf University, [2]Institute of Biometrics and Epidemiology, German Diabetes Centre, Düsseldorf, [3]Institute of Epidemiology, University of Ulm, Germany.

Background and aims: Seasonal variation of T1DM onset has been investigated in various studies and the results are conflicting. A sufficiently large cohort of cases is an important precondition for valid estimation of seasonal variation. Aim of the study was to investigate the seasonal variation of T1DM in children 0-14 years of age in the large risk population of the German federal state North Rhine-Westphalia (NRW) during the 12-year period 1996-2007.
Materials and methods: Data were taken from the NRW diabetes incidence register ascertaining newly diagnosed cases of T1DM by means of three data sources. During the study period a total of 7,128 newly diagnosed diabetic children aged 0-14 years (3,678 boys, 3,371 girls) were registered, the average risk population was 2.84 million children. The completeness of ascertainment was estimated to be 98%. Overall, sex- and age-specific (0-4, 5-9, 10-14 years) seasonal variation of the monthly T1DM incidence were analysed assuming a Poisson distribution of cases. The monthly expected mean of the incidence was modelled using a log-linear regression including a linear term for temporal trend and sinus and cosine terms for seasonal variation. The analyses were additionally adjusted for overdispersion of incidence data and, where appropriate, for sex and age at onset. Month of diagnosis was used as independent time variable. Seasonal variation was assumed to be constant over the study period.
Results: Overall, the average monthly incidence rates ranged between 16.6 per 100.000 person-years in July and 24.9 in January. Lower average incidences were found from April to August and higher incidences between September and March. According to the fitted sinusoidal regression model the seasonal variation of T1DM incidence was significant ($p<0.001$) with the trough at the end of June-July and the peak in December-January. The ratio of model-based maximum and minimum incidences was 1.34. Similar significant seasonal patterns ($p<0.001$) were observed among male and female patients, however, the amplitude was larger for males than for females (max/min-ratio: 1.46 vs. 1.24). Further, among males the trough was slightly earlier than among females. Significant seasonal variation was also detected for all age groups (0-4yrs: $p=0.005$; 5-9 and 10-14 yrs $p<0.001$). The magnitude of seasonal variation was similar in both older groups (max/min-ratio: 5-9 yrs: 1.43; 10-14 yrs: 1.38) but was considerably minor among the youngest children (max/min-ratio: 1.25). The model-based troughs in the age groups 0-4, 5-9 and 10-14 yrs were in May, June, and July, respectively.
Conclusion: This study based on a large cohort of T1DM cases showed significant seasonal variation in both sexes and all age groups. Seasonal patterns differed slightly between sexes and more distinctly between age groups. Seasonality of T1DM onset points to the importance of environmental factors in disease aetiology. Seasonal factors stressing beta cells (e.g. viral infections) may account for the variation. Delayed diagnosis in older children may account for the shift of the trough with age. Further research is needed to identify causes of the differing seasonal patterns between age groups.

Seasonal variability of HbA_{1c} in children and adolescents with type 1 diabetes

B. Mianowska, W. Fendler, A. Szadkowska, I. Pietrzak, E. Czerniawska, A. Zmysłowska, A.I. Baranowska, A. Ciepiela, W. Mlynarski;
Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University, Lodz, Poland.

Background and aims: Hemoglobin A1c (HbA1c) is an useful measure of average glycemic control and a widely accepted marker of the risk of long-term microvascular complications in people with type 1 diabetes (T1DM). The aim of the study was to determine whether there is a seasonal variability in glycated hemoglobin levels.
Materials and methods: Inclusion criteria to the study were: T1DM with duration of at least 1 year and patient's age below 18 years at inclusion. Data from the laboratory database were cross-referenced with the clinical database application and verified manually by two independent researchers. During the analyzed period Feb-2006 to Oct-2009 a total of 6001 HbA1c results were recorded within the laboratory. HbA1c was measured by means of ion-exchange high-performance liquid chromatography using the Bio-Rad VARIANT Hemoglobin A1c Program (Bio-Rad Laboratories, USA). Trend and autocorrelation of residuals were analyzed.
Results: Out of 6001 available measurements, 5656 valid results were analyzed. Median HbA1c was 7.40% (25-75% range: 6.80-8.30%). The highest concentrations of HbA1c were observed in February, November and December, while August and September showed the lowest HbA1c levels. The maximum difference between medians of HbA1c in any two months of the study period equalled 0.85% (Aug-2008 vs Feb-2006). Linear, decreasing trend of HbA1c values over the study period was statistically significant (Beta=-0.39; $p=0.008$). Detrended residuals of HbA1c levels showed a sine-wave pattern of autocorrelations with a period of 12-14 months, suggestive of positive correlation between months one year apart and of negative correlations for intervals of 6-7 months (Figure).
Conclusion: 1) HbA1c levels in young T1DM patients are seasonally variable and the lowest levels may be found in late summer. 2) Seasonal change in HbA1c levels should be considered in clinical practice and in short-time (lasting several months) clinical trials or research schedules.

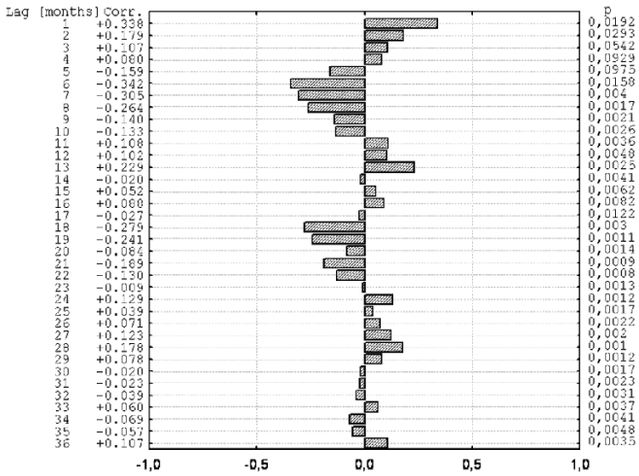

Figure – Autocorrelogram of HbA1c levels during the study period

Epidemiology of type 1 diabetes mellitus in children in Uzbekistan

G.N. Rakhimova, N. Alimova;
Centre for the Scientific and Clinical Study of Endocrinology, Tashkent, Uzbekistan.

Background and aims: Assessment and monitoring of basic epidemiological parameters of type 1 DM among children in the course of the 2000-2007 National Register.
Materials and methods: Epidemiological data was studied on the basis of annual reports from 13 regional endocrinological dispensaries and Tashkent endocrinological dispensary as well as on the basis of register cards filled up by local endocrinologists-pediatricians.
Results: In Uzbekistan within the period from 2000 to 2007 type 1 DM prevalence increased from 7.5 to 11.0 per 100,000 of pediatric population. The highest prevalence was observed in Tashkent (17.7), in Bukhara region (16.6) and in Tashkent region (14.5), the lowest one in Kashkadarya region (7.1) and in Surkhandarya region (7.7). Pediatric incidence in 2007 as compared with 2000 reduced from 2.7 to 2.1 per 100,000 of pediatric population. Analysis of pediatric incidence in 2007 revealed the highest one in Tashkent (4.6) and in Syrdarya region (2.7), the lowest being found in Navoi region (0.9). As to age distribution children aged from 10 to 14 comprised the largest group (66.6%),

the smallest including children from 0 to 4 years (5.0%), 28.3% accounting for patients aged from 5 to 9. As to the disease duration children with type 1 DM duration less than 5 years comprised the largest group (70.9%), in the smallest one (2.1%) including patients with 10-year DM duration. As a whole, in Uzbekistan within the period of the Register fulfilment mortality level reduced from 0.1 to 0.03 per 100, 000 of pediatric population. In 2007 mortality cases were registered in Kashkadarya region (0.1), Navoi region (0.4) and Samarkand region (0.09 per 100, 000 of pediatric population. As a whole in Uzbekistan mortality reduction in children with type 1 DM within the period from 1998 to 2007 was 99%.
Conclusion: Within the period of the National Register reduction in mortality paralleling alterations in structure of death cause and increase of survival can be noted to suggest perfect choice of strategy and tactics of the Register fulfillment.

927

The impact of intrauterine hyperglycaemia on glucose metabolism in the offspring five years after delivery

L. Bozkurt[1], C.S. Göbl[1], B. Rami[2], A. Handisurya[1], Y. Winhofer[1], E. Schober[2], A. Kautzky-Willer[1];
[1]Department of Internal Medicine III, Division of Endocrinolgy and Metabolism, [2]Department of Pediatrics, Medical University of Vienna, Austria.

Background and aims: Diabetes in pregnancy is associated with a higher risk of obesity and abnormal glucose homeostasis for the offspring in later life. The aim of the study is to assess features of glucose metabolism and insulin secretion as well as the prevalence of obesity in young children of diabetic mothers.
Materials and methods: In a prospective cross-sectional analysis data on anthropometric and metabolic parameters of 58 children (f:29; m:29) aged 4-9 years were collected. 13 mothers of these children had at the time of pregnancy a normal glucose tolerance (NGT) and served as a control group whereas 31 mothers were affected by gestational diabetes (GDM) and 14 women by Type 1 diabetes (T1D). Differences in BMI-SDS (Standard Deviation Score) were suggested as the primary outcome of this study. Further, a 2h-OGTT was performed in all children and circulating levels of adiponectin and leptin were measured.
Results: Children of mothers with T1D (-0.83±0.94) showed significantly higher BMI-SDS as compared to GDM (-0.11±0.94; p=0.003) and NGT (-0.20±0.88; p=0.021) exposed children. There were no differences between the NGT and GDM subgroups (p=0.77). However, the glucose profile during the 2h-oGTT was comparable (G0:p=0.51; G60:p=0.26; G120:p=0.47) and also indices of insulin resistance were not different (HOMA:p=0.64; Quicki: p=0.64). Regarding adipokine levels, we found no differences for Leptin (p=0.33) but when comparing adiponectin levels of GDM and T1D groups we found higher levels for T1D children (p= 0.047).
Conclusion: Children of women with T1D in pregnancy were more obese than children of mothers with NGT and GDM despite comparable plasma leptin concentrations and similar degree of insulin sensitivity at the age of five years. Further longitudinal studies are needed to detect as early as possible those children at highest risk in follow-up.

Plasma vitamin D and preservation of C-peptide in youth with recently diagnosed autoimmune positive type 1 diabetes: SEARCH Nutrition Ancillary Study

E.J. Mayer-Davis[1], K.Y. Wojcik[1], D. Dabelea[2], R.B. D'Agostino[3], J.M. Norris[4], I. King[5], C. Pihoker[6];
[1]Nutrition, University of North Carolina, Chapel Hill, [2]Epidemiology, University of Colorado Denver, Aurora, [3]Biostatistical Sciences, Wake Forest University, Winston-Salem, [4]Epidemiology, University of Colorado, Denver, [5]Internal Medicine, University of New Mexico, Albuquerque, [6]Seattle Children's Hospital, United States.

Background and aims: Preservation of insulin secretion following a diagnosis of diabetes predicts improved prognosis, yet little is known of the potential nutritional determinants of sustained beta cell function. We explored associations of plasma 25-hydroxyvitamin D concentration with baseline and short-term (~ 24 months) change in fasting c-peptide (FCP) within the SEARCH for Diabetes in Youth cohort diagnosed between 2002 and 2005.
Materials and methods: Included were 1224 youth (mean age at diagnosis, 9.8 yr) with at least one diabetes autoantibody positive (GAD65 or IA-2) and a clinical diagnosis of type 1 diabetes. About 77% were non-Hispanic white and gender was about equally distributed (52% male). Mean diabetes duration at baseline was 10 months. Mixed models regression analyses accounting for repeated measures were fit adjusting for onset age, sex, race/ethnicity, clinical center, baseline waist circumference, A1c, insulin regimen, HLA risk group and change in an index of insulin resistance. Vitamin D was analyzed as a continuous measure with values at the 25th, 50th, and 75th percentiles used for illustration.
Results: From the fully adjusted model, higher baseline vitamin D was associated with higher FCP at baseline (p=0.04) but unexpectedly was associated with more rapid decline in FCP (see figure; fully adjusted p-value=0.009).
Conclusion: Higher plasma vitamin D may provide some protection of the beta cell near the time of T1D diagnosis, although this protective effect appears to be of limited durability. The mechanisms for a potential protective effect of vitamin D on beta cell function near the diagnosis of diabetes, and whether such an effect would hold clinical significance, remains to be determined.

The benefits of continuous subcutaneous insulin infusion in children with type 1 diabetes mellitus started at diabetes recognition. A 7 year follow-up

A. Szypowska, K. Dżygało, A. Ramotowska, M. Lipka, M. Procner-Czaplińska, H. Trippenbach-Dulska;
Medical University of Warsaw, Poland.

Background and aims: Intensive management, achieved by multiple daily insulin injections (MDI) or continuous subcutaneous insulin infusion (CSII), improves long-term outcomes in patients with Type 1 diabetes (T1DM). CSII and MDI are both effective in achieving near-euglycaemia, but CSII offers the opportunity to change the basal infusion rate according to the needs of patients and allows precise insulin dosing to cover a different kind of meals. In pediatric patients, CSII has been demonstrated to achieve glucose target and reduce frequency of severe hypoglycemia, without sacrifices in safety, quality of life, or excessive weight gain. In long-term follow up patients treated at T1DM onset with CSII therapy may achieve better metabolic control than patients switched from injections to CSII. The aim of this study was to compare efficacy of CSII at diabetes recognition with CSII after MDI in children with T1DM. The primary end-point was glycated haemoglobin.
Materials and methods: 169 children with T1DM treated with CSII for at least 5 years were divided into two groups depending on time of starting CSII therapy. I group: 97 children (girls) with mean age 6.7±2.3 years switched from MDI to CSII, the mean time with MDI therapy was 2.2±1.6 years; II group: 72 children (girls) with mean age 6.2±2.1 years started with CSII within 3 month after diabetes onset. Data was collected every three months: HbA1c, BMI, diabetic ketoacidosis (DKA) and severe hypoglycaemia (SH), total daily insulin dose was downloaded from pump memory.
Results: During the 7-year follow-up better metabolic control was achieved in the group II, the differences between group I and group II from the 2nd to the 4th year were not quite significant (2nd yr:7.33 vs. 7.08; 3rd yr: 7.33 vs. 7.09; 4th yr: 7.54 vs. 7.26%) , and statistically significant: in the 1st year (7.58 vs. 7.13%) and from the 5th to the 7th year (5th yr: 7.89 vs. 7.27; 6th yr: 8.11 vs. 7.48; 7th yr: 8.18 vs. 7.45%) p<0.05 . In the group II HbA1c was <7.5%

and in the group I increased to 8.2% at the time of follow-up. TDD increased from 0.4U/kg/d to 0.7U/kg/d p<0.0001. The insulin daily dose increased in the I group from 0,7 to 0.87 U/kg/die and in the II group from 0.48 to 0.87 U/kg/die, the significant differences between both groups were observed in the 1st and 2nd year. BMI increased in the I group from 16.3 after the 1st year to 19.8 kg/m2 after the 7th year and in the group II from 15.9 after the 1st year to 18.4 kg/m2 after the 7th year. BMI was significantly higher in the group I in the 6th and 7th year of the follow-up. There was no significant difference between both groups in the number of episodes of DKA and SH.
Conclusion: In longitudinal observation children started with CSII at diabetes recognition achieved better metabolic control than children initiated with CSII after MDI. The long- term benefits of CSII therapy started at T1DM onset should be taken under consideration before making a decision on CSII initiation.

Long-term efficacy of insulin pump therapy in young children with diabetes
R. Bonfanti, F. Meschi, M. Viscardi, A. Rigamonti, V. Biffi, G. Frontino, R. Battaglino, V. Favalli, C. Bonura, G. Chiumello;
Department of Pediatrics, San Raffaele Scientific Institute, Milano, Italy.

Background and aims: To compare effectiveness of continuous subcutaneous insulin infusion (CSII) to multiple daily injections with rapid-acting insulin analogues and NPH insulin (MDIs) in preschoolers after more than 1 year of treatment.
Materials and methods: We evaluated 25 preschool patients (11 males, 14 females) with a history of type 1 diabetes of at least one year duration (14 CSII, 11 MDIs). Outcomes included measures of: glycated haemoglobin (HbA1c), mean blood glucose (BG) and standard deviation (SD), percent of BG values above and below target regarding the last 3 months of follow up, and the average daily risk range (ADRR) regarding the last month of follow up. Unpaired nonparametric two-tailed Mann-Whitney tests were used to analyze data from the two groups.
Results: The 25 subjects' ages ranged from 2 to 6 years (mean age CSII 4,6 yrs; mean age MDII 4.6 yrs), duration of diabetes ranged from 1 to 4.9 years (mean disease duration CSII: 2.9; mean disease duration MDIs: 2.3), duration of CSII ranged from 1 to 3.9 years (mean CSII duration 2.45 yrs). Comparison of overall metabolic control showed no statistically significant differences between the two groups when considering HbA1c (CSII 7.09%; MDIs 7.38%), mean BG (CSII 161.8 mg/dL; MDIs 168 mg/dL) and SD (CSII 82.1 mg/dL; MDIs 85.2 mg/dL), and percent of BG values below target (CSII 12,7%; MDIs 15.2%). However a statistically significant difference was found when comparing percent of BG values above target (CSII 35.1%; MDIs 47.2%; p<0.05). Furthermore, the MDIs group showed ADRR values consistent with moderate risk of BG excursions, while the CSII group showed an ADRR value consistent with high risk. However, no statistically significant differences were found regarding ADRR values of the two groups (CSII 44.9; MDIs 35.6).
Conclusion: Although CSII can be a safe and effective method to deliver insulin in young children, long-term pump therapy in our young patients was not associated with significant differences in glycemic control as compared with intensive injection therapy, confirming short-term results from past studies. Our study also showed that both CSII and MDII may allow the achievement of target glycemic control (HbA1c < 7.5 for all age-groups according to ISPAD 2009 guidelines), underlining that optimal control may be obtained independently of the means of insulin administration. Furthermore, evaluation of ADRR showed a greater risk for glycemic excursions in the CSII group, although comparison of ADRR values between the two groups showed no statistically significant difference. Consequently, rationale for initiating CSII in this age group should be primarily based on patient/parent selection and lifestyle preference. Nonetheless, further studies involving sensor augmented CSII in this age group are warranted in order to evaluate potential benefits on diabetic complications, thus going beyond lifestyle improvements which currently appear to be the only achievement in preschoolers.

931

Intervention with metformin in childhood diabetes may slow decline of C peptide - the accelerator hypothesis
L.M. Saranac, B. Bjelakovic, S. Zivanovic, M. Novak;
Pediatric Clinic Clinical Centre Nis, Serbia.

Background and aims: Diabetes results from beta cell insufficiency. The accelerator hypothesis proposes that type 1 and type 2 diabetes are not different disorders, but poles of a single spectrum. Variable interaction between insulin resistance and the immune response to it determines the tempo of beta cell loss, and with it age at onset and incidence. The hypothesis is sufficiently well developed to consider use of metformin in children with new onset of type 1 diabetes. The aim of the study was to investigate the impact of metformin on the progression of childhood diabetes.
Materials and methods: Twenty-one children, mean age 10,9± 2,8y with recently diagnosed and insulin-treated type 1 diabetes were studied. Metformin was added after two weeks as insulin sensitizer and apoptosis reducing agent. Inclusion criteria were basal C peptide over 0.2 nmol/l and preserved pulsatility of insulin secretion. Twenty-six children and adolescents on insulin monotherapy acted as controls.
Results: Insulin was gradually reduced according to daily glycemic profiles and the metformin-treated children entered remission faster. Six of them achieved complete remission for longer than 12 months. Mean C-peptide level after 18 months was 0.57 nmol/l in metformin group versus 0.20 in the group on insulin alone (p<0.05). HbA1C tended to be lower in the metformin group; (7.7 % compared with 9.0 % , NS) .
Conclusion: Our first experiences with combined treatment (insulin and metformin) are favourable, suggesting that metformin use in childhood diabetes may reverse C peptide decline. Further studies are necessary.

932

Relationship between depressive symptoms and quality of life and metabolic control in children and adolescents with diabetes type 1
B.M. Zdunczyk[1], J. Sendela[2], K. Dżygało[3], H. Trippenbach-Dulska[3], M. Lipka[2], M. Procner-Czaplińska[2], A. Szypowska[3];
[1]Clinical Pediatric Hospital, [2]The Department of Pediatrics, Clinical Pediatric Hospital, [3]The Department of Pediatrics, Medical University of Warsaw, Poland.

Background and aims: As many studies show depression is a factor involved in pathogenesis of diabetes and a major complication affecting metabolic control in patients with diabetes. There is a higher incidence of diabetes among patients with depression and patients with diabetes and depressive symptoms achieve worse metabolic control. These studies are usually conducted on adults with diabetes type 2. It is still little known about children and adolescents with diabetes type 1. The aim of this study was to assess the prevalence of depression and examine its effect on metabolic control and quality of life in children and adolescents with diabetes type 1.
Materials and methods: 214 children so far took part in this study: 107 girls and 107 boys. Mean age: 13.1 <7-17, SD 2.7>. Mean diabetes duration: 5.2 (SD 2.7). During the routine visit in the outpatient clinic all children and adolescents with diabetes type 1 age 7 and above were asked to fill in Children's Depression Inventory (Polish version), a self-report questionnaire consisting of 27 items. Patients from age 11 and above were asked to answer questions in Quality of Life Questionnaire, a 58 item questionnaire based on the DCCT Diabetes Quality of Life Measure. At the same time other data was collected: sex, age, diabetes duration, HbA1c, BMI, daily insulin dose.
Results: 35 participants (16.35%) scored ≥ 13, indicating elevated depressive symptoms. In the group with scores below 13 (179) there were 76 participants (42.45%) who scored above average in one of subscales. There was an extremely significant correlation between scores on the CDI and quality of life (r=0.6510, p<0.0001). A very significant correlation was found between scores on the CDI and HbA1c (r=0.2088, p=0.005) and age of participants (r=0.2000, p=0.005). There was also a significant correlation between scores on the CDI and diabetes duration (r=0.1576, p=0.023), BMI (r=0.1356, p=0.049) and insulin daily dose (r=0.1785, p=0.011). There was no difference between girls and boys on the CDI scores.

Conclusion: 16.35% participants show elevated depressive symptoms as assessed with Children's Depression Inventory. 42.45% participants without depressive symptoms score above the average on one of the CDI subscales. Children and adolescents with higher scores on the CDI have worse quality of life and achieve worse metabolic control. The longer diabetes duration and the older participant the more likely he presents depressive symptoms. It is necessary to pay attention to emotional wellbeing of children and adolescents with diabetes type 1, especially the older ones who are longer ill. It is necessary to develop an intervention program aimed at prevention of emotional problems in youths with diabetes.

933

Longitudinal associations between depressive symptoms and glycaemic control among adolescents and young adults with type 1 or type 2 diabetes

J.M. Lawrence[1], K. Hood[2], A. Anderson[3], J.P. Yi-Frazier[4], L.D. Case[3], D. Dabelea[5], R. Bell[3], D.E. Williams[6], R. McKeown[7];
[1]Kaiser Permanente Southern California, Pasadena, [2]Cincinnati Children's Hospital, Cincinnati, [3]Wake Forest Univ., Winston-Salem, [4]Univ. of Washington, Seattle, [5]Univ. of Colorado Denver, [6]Centers for Disease Control and Prevention, [7]Univ. of South Carolina, Columbia, USA.

Background and aims: Depression is associated with poor glycemic control in youth with diabetes (DM). We assessed the association between depression scores and change in depression score over time with change in A1c among youth in the SEARCH for Diabetes in Youth study.
Materials and methods: 861 youth (age 15.3 ± 2.5 years; 78% type 1 DM; 50% female; 81% non-Hispanic White) had a baseline visit (time1) within ≈ 1 year of DM diagnosis and completed a follow-up visit (time2). At each visit, symptoms of depression were evaluated with the Center for Epidemiologic Studies-Depression (CES-D) scale, blood was drawn for A1c analysis, and DM duration was assessed. CES-D score was categorized to indicate minimal (0-15), moderate (16-23) and frequent (24-60) symptoms of depression, and also used as a continuous measure in regression analyses. A linear regression model was fit to examine the effects of CES-D score at time1 and the change in CES-D score from time1 to time2 (predictors) on the change in A1c from time1 to time2 (outcome) adjusting for age, gender, race/ethnicity, DM type, DM duration, BMI-Z score, and presence of co-morbidities, all measured at time1, as well as time between visits.
Results: Youth had DM for 26.8±9.1 months at their time2 visit which was, on average, 17.2±6.0 months after their time1 visit. At time1, 80%, 13%, and 8% had minimal, moderate, and frequent symptoms of depression, respectively, while a similar distribution observed at time2. CES-D category at time1 and time2 were significantly associated ($p<0.001$); continuous scores on the CES-D were also correlated ($r=0.56$, $p<0.0001$). Of youth with minimal symptoms at time1, 87% remained minimal at time2 while 8% were moderate and 5% had frequent symptoms of depression. Of youth with moderate symptoms at time1, 56% improved while 17% moved to the frequent category at time2. Of those with frequent symptoms at time1, 34% stayed the same, while 29% were in the moderate and 37% in the minimal symptom categories. In the multiple linear regression analyses, there was a positive association between both the CES-D score at time1 and change in CES-D from time1 to time2 and change in A1c. Larger changes in CES-D and higher CES-D scores at time1 were both associated with greater increases in A1c. Race/ethnicity, gender, DM duration and BMI-Z were also significant in the final model while DM type was not.
Conclusion: Most youth with minimal symptoms at time1 remained in that category at time2 while about 2/3 of youth with frequent symptoms experienced some improvement. Youth who had more frequent symptoms of depression as well as a greater increase in symptoms tended to have worsening glycemic control at follow-up while improvement in depressive symptoms was associated with improved glycemic control. Screening for and treatment of depressive symptoms in adolescents and young adults with DM may help improve glycemic control in this population.

Dose-dependent effects of protein 'preloads' on gastrointestinal hormones, glycaemia, and energy intake in type 2 diabetes

J. Ma[1,2], J.M. Wishart[1,2], K.L. Jones[1,2], M. Horowitz[1,2], C.K. Rayner[1,2];
[1]Discipline of Medicine, University of Adelaide, Royal Adelaide Hospital, [2]Centre of Clinical Research Excellence in Nutritional Physiology, University of Adelaide, Australia.

Background and aims: Whey protein 'preloads' can stimulate glucagon-like peptide-1 (GLP-1), glucose-dependent insulinotropic polypeptide (GIP), insulin and cholecystokinin (CCK) release, slow gastric emptying of a subsequent meal, and improve postprandial glycaemia. We aimed to determine the effects of different doses of whey, when ingested before a buffet-style meal, on gastrointestinal hormones, glycaemia, and energy intake in type 2 diabetes.
Materials and methods: Nine patients with diet-controlled type 2 diabetes (glycated haemoglobin 6.7 ± 0.3 %) were studied on 3 separate days in randomized order. Subjects consumed a chocolate-flavoured liquid 'preload' (100 ml water mixed with either a flavoured 'placebo' (8 kcal), or with 25 g (89 kcal) or 55 g (195 kcal) flavoured whey protein), 30 minutes before an ad libitum meal (T = 0 to 30 min). Blood was sampled frequently for hormone measurements.
Results: Data are shown as mean ± standard error. Both whey preloads stimulated GLP-1, GIP, insulin and CCK before the meal ($P < 0.05$); the stimulation of insulin and CCK were greater ($P < 0.05$) with 55 g whey. The incremental area under the curve (iAUC) for GLP-1 was greater after 55 g whey than the other days, while iAUC for insulin was greater after 25 g and 55 g whey than placebo. The peak postprandial blood glucose was slightly lower with 25 g and 55 g whey than placebo ($P < 0.05$). Both whey preloads increased postprandial fullness slightly ($P < 0.05$), but neither affected energy intake.
Conclusion: Acute administration of a whey protein 'preload' in patients with diet-controlled type 2 diabetes dose-dependently stimulated GIP, GLP-1, insulin and CCK, and reduced postprandial glycaemia, as well as increasing fullness, but had no significant effect on energy intake.

Sustained effects of a protein 'preload' on gastric emptying and glycaemia in type 2 diabetes over 4 weeks

M. Horowitz[1,2], J. Ma[1,2], D.R. Jesudason[2,3], A. Russo[1,2], J.E. Stevens[1,2], J.B. Keogh[2], K.L. Jones[1,2], P.M. Clifton[2], C.K. Rayner[1,2];
[1]Discipline of Medicine, University of Adelaide, Royal Adelaide Hospital, [2]Centre of Clinical Research Excellence in Nutritional Physiology, University of Adelaide, [3]Endocrine & Metabolic Unit, Royal Adelaide Hospital, Australia.

Background and aims: Whey protein 'preloads' acutely reduce glycaemia after a subsequent meal in type 2 diabetes, associated with slowing of gastric emptying and stimulation of incretin and insulin release. The aim of the current study was to evaluate whether the effects of protein preloads on gastric emptying and glycaemia are sustained with 'chronic' (4 weeks) administration.
Materials and methods: Seven patients with uncomplicated type 2 diabetes treated by diet alone (glycated haemoglobin 5.9 ± 0.2 %) participated in the study. Each consumed a chocolate-flavoured 'preload' (containing either 25 g whey or placebo), 30 min before each of the three main meals for 4 weeks, followed by a 'washout' period of 2 weeks, and then the alternative preload for 4 weeks, in a randomized crossover design. Gastric emptying of (scintigraphy), and the glycaemic response to, a standard potato meal consumed 30 min after the preload, were measured at the beginning and end of each 4 week period, as was serum fructosamine.
Results: Data are shown as mean ± standard error. Whey slowed gastric emptying and reduced postprandial blood glucose compared to placebo, both at baseline and after 4 weeks exposure to whey (repeated measures ANOVA, $P < 0.05$ for all comparisons), without any difference between baseline and 4 week values. Fructosamine was non-significantly lower after 4 weeks whey than placebo (253 ± 15 vs 279 ± 10 μmol/L, $P = 0.15$).
Conclusion: Administration of a whey preload for 4 weeks results in sustained slowing of gastric emptying and reduction in postprandial glycaemia in type 2 diabetes. A larger trial of longer duration is indicated to determine whether this strategy can improve glycaemic control.

936

Thorough chewing stimulates postprandial increases of plasma GLP-1 and peptide YY in normal subjects

M. Eto, M. Saito, Y. Hattori, R. Terasawa;
Clinical Medicine, Ohu University, Koriyama, Japan.

Background and aims: Glucagon like peptide (GLP)-1 and peptide YY (PYY) are secreted from intestinal L cells, and plasma levels of both hormones rise after a meal. GLP-1 stimulates glucose-dependent insulin secretion. PYY decreases appetite and reduces food intake by acting on receptors in the hypothalamus. GLP-1 also reduces food intake. Therefore, GLP-1 and PYY seem important to control plasma glucose and triglyceride (TG) levels and body weight. On the other hand, it has been conventionally thought that "chewing well" i.e. "thorough chewing" is good for health. Much remains unknown on the relationship between thorough chewing and GLP-1 and PYY which are secreted from intestine after a meal. The aim of this study is to investigate effects of thorough chewing on postprandial levels of plasma GLP-1 and PYY in normal subjects.
Materials and Methods: Twenty two normal subjects were recruited. They were not obese and not diabetic. Plasma mean fasting glucose was 96 mg/dl. Mean age was 37 years and mean BMI was 23.1. The subjects were given the test meal early in the morning after 12h fasting. They ate it for 20 minutes and chewed each mouthful 5 times (5 times chewing). On the other day the subjects ate it for 20 minutes and chewed each mouthful 30 times (30 times chewing, i.e. thorough chewing). Plasma GLP-1 and PYY were measured before and 1 h after ingestion of the test meal. Plasma glucose and insulin were measured before and 1 h after ingestion of the test meal. Plasma TG was measured before and 2 h after ingestion of the test meal. The test meal consisted of bread, margarine, a boiled egg, steamed vegetables, a banana, and milk. Total calories were 630 kcal, with 16% protein, 32% fat, and 52% carbohydrate. Plasma PYY was measured as PYY(3-36) using an enzyme immunoassay kit. Plasma GLP-1 was measured as GLP-1(7-36) using ELISA kit.
Results: Plasma mean PYY levels with 5 times chewing tended to increase from 41.0 pg/ml (before a meal) to 46.1 pg/ml (after a meal). Plasma PYY levels with 30 times chewing significantly increased from 41.7 pg/ml (before a meal) to 65.4 pg/ml (after a meal). Postprandial PYY level with 30 times chewing was significantly higher than with 5 times chewing. Plasma mean GLP-1 levels with 5 times chewing significantly increased from 4.8 pmol/l (before a meal) to 18.9 pmol/l (after a meal). Plasma GLP-1 levels with 30 times chewing significantly increased from 5.0 pmol/l (before a meal) to 25.1 pmol/l (after a meal). Postprandial GLP-1 level with 30 times chewing was significantly higher than with 5 times chewing. Plasma mean TG level with 5 times chewing significantly increased from 107 mg/dl (before a meal) to 170 mg/dl (after a meal). Plasma TG level with 30 times chewing significantly increased from 114 mg/dl (before a meal) to 147 mg/dl (after a meal). Postprandial TG level with 30 times chewing was significantly lower than with 5 times chewing. There was no significant difference in increases of plasma glucose and insulin after a meal between 5 times and 30 times chewing in normal subjects.
Conclusions: This is the first report that thorough chewing stimulates postprandial increases of plasma GLP-1 and PYY in normal subjects. In addition, thorough chewing suppresses postprandial increase of plasma TG level. Thorough chewing may be clinically effective in normal subjects.

937

Carbohydrate substitution for protein, fat, and their subtypes and risk of type 2 diabetes in men

M.E. Similä[1], J.P. Kontto[1], L.M. Valsta[1], D. Albanes[2], J. Virtamo[1];
[1]National Institute for Health and Welfare, Helsinki, Finland, [2]National Cancer Institute, Bethesda, USA.

Background and aims: Interest in optimal macronutrient proportions to avoid type 2 diabetes has grown recently. We examined the associations of intakes of carbohydrates, protein, fat, and their subtypes (low, medium, and high GI carbohydrates; protein from meat, milk products, and plant sources; and fatty acids) with diabetes risk.
Materials and methods: The cohort comprised 25 943 Finnish male smokers aged 50-69 years. Diet was assessed at baseline with a validated diet history questionnaire. During a 12-year follow-up, 1 098 incident diabetes cases were identified from a national register. Cox proportional hazard modeling was used to estimate the risk for diabetes and multivariate nutrient density models to examine the effects of substitutions of different macronutrients.
Results: The substitution of carbohydrates for protein was inversely associated with diabetes risk: change in the multivariate relative risk when carbohydrates replaced two percent of energy of protein was 0.85 (95% CI: 0.80, 0.90). The substitutions of carbohydrates for protein subtypes, protein from meat, milk products and plant origin, were each inversely associated with diabetes risk, but plant protein intake itself showed no association with diabetes risk. The substitution of carbohydrates for total fat was also inversely associated with diabetes risk, but not significantly for all the fatty acids.
Conclusion: Greater carbohydrate intake at the expense of protein, especially from meat or milk products, was associated with decreased diabetes risk. Carbohydrate intake at the expense of total fat intake was associated with decreased diabetes risk, but the beneficial association may depend on which fatty acids are substituted.

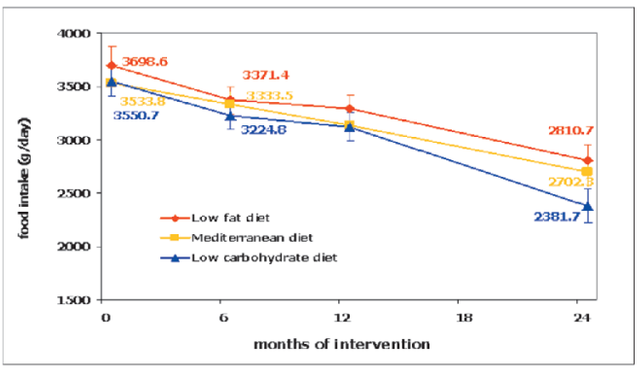
Effect of changes in the intake of specific food groups on weight loss; a two year dietary intervention trial

Y. Gepner[1], A. Canfi[1,2], D. Schwarzfuchs[2], R. Golan[1], D. Shahar[1], D. Fraser[1], S. Witkow[1], I. Greenberg[1], H. Vardi[1], B. Sarusi[2], M. Friger[1], M.J. Stampfer[3], I. Shai[1];
[1]Epidemiology and Health Systems Evaluation, Ben Gurion University of the Negev, Beer-Sheva, Israel, [2]Nuclear Research Center Negev, Dimona, Israel, [3]Harvard School of Public Health, Channing laboratory, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, and Departments of Epidemiology and Nutrition, Boston, USA.

Background and aims: Adherence to distinct dietary strategies is associated with changes in specific food-groups consumption. We aimed to address the effect of changes in the intake of specific *weight* of food-groups on weight-loss in a 2-year low-fat, Mediterranean and low-carbohydrate dietary intervention trial.
Materials and methods: Electronic-food-frequency questionnaires were used to assess changes in the intake of 11-food-groups (beverages, vegetables, fruits, dairy products, meat, breads/cereals/pasta/potatoes, sweets/cakes, legumes, fish, fats/oils, and eggs) among patients with type 2 diabetes (n=45) and non-diabetics (n=277) moderately obese participants (BMI=31kg/m^2; age=52years; 86%men).
Results: Mean weight-losses at 6-months were -4.6kg, -4.7kg and -6.4kg for the low-fat, Mediterranean and low-carbohydrate groups, respectively ($p<0.026$ between groups). Reduction in total weight of food consumption, however, was similar across diet-groups (Figure 1): from 3,593 g/day, the participants reduced ($p<0.005$) their food intake by -284g/day at 6-months and by -963g/day at 24-months. In multivariate regression models, adjusted for age, sex, baseline body-weight and simultaneous *changes* of 11-food-groups weight intake (g/day), independent dietary predictors of 6-month weight-loss (rapid weight-loss-phase) were: decreased consumption of sweets and cakes ($\beta=0.493;p=0.008$) in the low-fat, increased intake of crude legumes ($\beta=-0.196;p=0.061$) in the Mediterranean, and increased vegetables intake ($\beta=-0.249;p=0.018$) in the low-carbohydrate diet-group. In the entire study population, in models further adjusted for diet-type, the leading predictors for weight loss after 6-months were increased vegetables ($\beta=-0.116;p=0.045$) and decreased sweets and cakes intake ($\beta=0.162;p=0.010$). Predictors for 2-year successful weight loss in the entire group were: increased vegetables ($\beta=-0.192;p=0.007$) and meat ($\beta=-0.146;p=0.026$) and decreased eggs ($\beta=0.187;p=0.003$), processed legumes ($\beta=0.195;p=0.002$), and beverages intake ($\beta=0.135;p=0.032$). Analyses were similar when stratifying by diabetes status.
Conclusion: Weight loss may be achieved by a variety of changes in specific food-groups consumption within different diet strategies, while in overall, the leading universal predictors for weight loss are increased vegetables and decreased sweets and cakes intake.

Figure 1: Total weight of food intake (g/day) at baseline, 6 and 24 months, across dietary intervention groups



- tested with ANOVA for between groups and with paired Student t-test for within group comparisons. N=321.
- All diet groups reduced significantly their food intake from baseline to 6 and 24 months, (within groups $p<0.005$).
- No significant differences were observed between the diet groups. Vertical bars indicate standard errors

939

Special dietary regimen and nutrient intake of patients with type 1 diabetes

A.J. Ahola[1,2], V. Mikkilä[2], S. Mäkimattila[1], C. Forsblom[1,3], R. Freese[2], P.-H. Groop[1,3], on behalf of the FinnDiane Study Group;
[1]Folkhälsan Research Center, Helsinki, [2]University of Helsinki, [3]Helsinki University Central Hospital, Finland.

Background and aims: Patients with type 1 diabetes are instructed to eat a healthy, balanced diet with the aim to optimize metabolic control. Type 1 diabetes is, however, associated with a number of conditions that may require dietary modifications. We aimed to evaluate the frequency of adhering to special dietary regimen and to study whether such adherence would rise any concern in the sufficiency of dietary intake.
Materials and methods: Cross-sectional data were collected from 810 participants [40% men, mean age 47 (range 18-84) years, diabetes duration 32 (1-68) years] in the Finnish Diabetic Nephropathy Study. Data on energy and nutrient intake were collected with a three-day food record (two weekdays and a weekend day) that was completed twice with a 2-3 month interval. Self-report questionnaire was applied to assess adherence to a lactose free, protein restriction, gluten free, or vegetarian diet. Whether diet was introduced based on a recommendation from a health care professional or was self-initiated, was also enquired.
Results: A total of 225 (28%) patients reported adhering to a special diet. Adherence to a lactose free diet was the most frequent (15%), followed by protein restriction (7%), vegetarian (6%) and gluten free diet (4%). Vegetarian (93%) and lactose free (63%) diets were most frequently self-initiated, while gluten free and protein restriction diets were primarily initiated based on a diagnosis (88% and 85%, respectively). Frequencies of reaching the recommendations for carbohydrate intake (45-60 E%) ranged from 50% (gluten free) to 63% (vegetarian). Those not reaching the recommendations mainly consumed less carbohydrates than recommended. A total of 24% (protein restriction) to 37% (vegetarian) of the patients exceeded the recommendations for sucrose intake (<10 E%). Recommendations for protein intake (10-20 E%) were frequently met in all four groups (86 to 92%). At least 50% of patients in all groups met the recommendations for total fat (25-35 E%), monounsaturated fatty acids (10-20 E%), and polyunsaturated fatty acids (5-10 E%). However, a substantial proportion of patients exceeded the recommended levels for total fat (28 to 46%) and saturated fatty acid (<10 E%) intakes (61 to 84%). Moreover, the proportion of patients achieving the recommendations for fibre (0 to 3%) and salt intake (30 to 50%) were low in all four groups. Mean intakes of vitamin A and D per 1000 kcal were below recommendations in all special diet groups. The mean intake of folic acid was below recommendations among all but those adhering to a vegetarian diet. Moreover, those on a gluten free diet did not, in average, meet the recommended level for iron intake.
Conclusion: Special diets were found to be common among patients with type 1 diabetes. Dietary intake of those following a special dietary regimen did not, for many parts, meet the recommendations. Particular attention should be paid to fibre, saturated fatty acid, salt, vitamin A and vitamin D intakes. Moreover, those adhering to gluten free diets are encouraged to address their iron intake.

Glycaemic responses of RP-13 (Bangladeshi Origin) and Jasmine (Thailand) rice in type 2 diabetic subjects

F. Rahman[1], N. Sumi[1], K. Kobura[1], C.B. Mikkelsen[2], K. Fatema[1], L. Ali[3];
[1]Dept of Epidemiology and Biostatistics, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh, [2]ISIS Food Products, Skanderborgvej, Denmark, [3]Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh.

Background and aims: In the context of the importance of Glycemic Index (GI) and Glycemic Load (GL, an applied tool calculated from GI and serving size) in determining the health of carbohydrate rich foods. The present study was carried out to determine these parameters for Jesmine Rice (Thailand origin) and RP-13 rice (produced in Bangladesh by ISIS Food Products, Denmark), Insulinemic response and NEFA response, as important covariables, were also determined.
Materials and methods: Eighteen diabetic subjects (male 12, female 6), under a cross-over design, consumed equi-carbohydrate amount of the test

foods and two times glucose (as reference food), with a run in period of 7 days between the consecutive items. The (mean±SD) age (years) of the patients was 41± 6, waist hip ratio 0.93 ± 0.04, body mass index (BMI) 25 ± 3 and they had basal serum HbA_1c value of 6.56 ± 0.83 %. The test meals contained 50 g of total carbohydrate and were given to the participants for ingestion within 10 minutes with 200 ml water. Serum levels of glucose were estimated at 0, 30, 60, 90, 120, 150 and 180 minutes respectively. NEFA, TG and Insulin levels were measured at 0 and 180 minutes only. Serum glucose and TG were measured by glucose-oxidase method, serum Insulin by chemiluminescent ELISA, NEFA by colorimetric method and HbA_1c was measured by HPLC method.

Results: RP-13 showed significantly lower serum glucose value than that of Glucose and Jasmine rice (Incremental area under the curve 289.4±111.3 in RP-13 vs. 591.4±198.8 in Glucose and 499.1±180.3 in Jasmine Rice; (*p<0.001*)). RP-13 had significantly lower GI value than that of Jasmine rice [(Mean±SD): 51.5 ± 8.3 in RP-13 vs. 86.4 ± 21 in Jasmine rice (*p<0.001*)]. The GL of RP-13 and Jasmine rice are 22 and 41 respectively. There were no significant difference between RP-13 and Jasmine Rice regarding serum Insulin, serum TG and serum NEFA responses.

Conclusion: As judged against the mean values of the international table (GI: High ≥ 70, Medium 56-69 and low ≤ 55; GL: High ≥ 20, Medium 11-19 and low ≤ 10) RP-13 is a low GI and Jasmine is a high GI rice. However, from the dietary practices in Bangladesh both the items may be used as high GL rice. The data emphasizes the necessity of constructing GI and GL tables based on studies from individual societies.

941

Both higher serum vitamin D and dairy calcium intake are related to a greater 2-year diet induced weight loss, especially in diabetes

R. Golan[1], D.R. Shachar[1], D. Schwarzfuchs[2], D. Fraser[1], Y. Gepner[1], O. Tangi-Rosental[1], H. Vardi[1], J. Thiery[3], G. Fiedler[3], M. Blüher[3], M. Stumvoll[3], M. Stampfer[4], I. Shai[1];
[1]Epidemiology, Ben Gurion University, Beer Sheva, Israel, [2]Epidemiology, Nuclear Research Center Negev, Dimona, Israel, [3]Medicine, Department of Medicine and Institute of Laboratory Medicine, University of Leipzig, Germany, [4]Public Health, Channing laboratory, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, and Departments of Epidemiology and Nutrition, Harvard School of Public Health, Boston, Boston, USA.

Background: The role of serum 25-OH vitamin D levels and dairy calcium intake on weight loss is controversial.

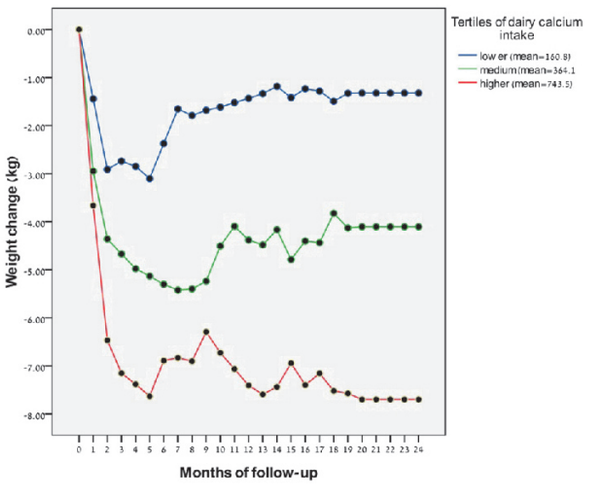
Objective: To address the association of dairy calcium intake and serum 25-OH vitamin D levels with long-term weight loss in persons with type 2 diabetes (T2D) and with persons with normal glucose tolerance (NGT).

Design: We analyzed the 2-year Dietary Intervention Randomized Controlled Trial (DIRECT)[NGT: n=277, T2D: n=45, mean body-mass-index (BMI)=31kg/m^2;mean age=52years]. A representative sample (n=126) was followed for 6-months for serum vitamin D changes. Dietary intake, including dairy products, was evaluated by a validated food frequency questionnaire (FFQ).

Results: Serum baseline 25-OH Vitamin D levels were significantly lower within the higher tertile of baseline BMI in both groups (entire group: 25.6ng/m, 24.1ng/ml and 22.9ng/ml; p for tend=0.02). Baseline levels of vitamin D and dairy calcium intake were not associated with subsequent weight loss. In repeated measures models, adjusted for age, sex, baseline BMI, total fat intake and diet group assignment, the six months tertiles of dairy calcium intake (mean for tertiles: T2D: 160.8mg/day, 364.1mg/day, 743.5mg/day, NGT: 153.3mg/day, 353.9mg/day, 638.2mg/day) and the six months tertiles of serum 25-OH vitamin D (T2D: 14.0ng/ml, 21.1ng/ml, 30.4ng/ml, NGT:13.8ng/ml, 20.8ng/ml, 31.0ng/ml) were associated with weight loss across the two-years of intervention. However, these associations were much stronger in persons with T2D. (-1.3kg; -4.1kg and -7.7kg; across tertiles of dairy calcium; p=0.018, and -0.8kg, -5.3kg and -8.7kg; across tertiles of serum 25-OH vitamin D; p=0.042).

Conclusion: Higher dairy calcium intake and increased serum vitamin D are related to greater dietary-intervention two-year weight loss, especially among persons with type 2 diabetes.

Figure 1: Adjusted* weight change among diabetics across 6 months tertiles of dairy calcium intake (reflecting the dairy intake in the previous 6 months)



* Adjusted means, repeated measure model, adjusted for age, sex, baseline BMI, total fat intake and assigned diet group. Mean levels of dairy calcium intake tertiles among T2D=160.8±62.0mg/day, 364.1±44.3mg/day, 743.5±202.7mg/day, respectively.

Nutritional assessment in type 2 diabetic elderly patients admitted to an internal medicine ward

M.C.M. Carvalho[1], R. Carvalho[2], H. Figueiredo[3];
[1]Nutrition, [2]Endocrinology, [3]Internal Medicine, ULS Guarda EPE, Seia, Portugal.

Background: Type 2 Diabetes is more prevalent in elderly people (≥ 65 years) contributing to a major malnutrition risk in this age group. There are few data about nutritional state in elderly diabetic patients in Portugal.

Aim: The authors pretended to evaluate nutritional state in type 2 diabetic patients over 65 years admitted to the internal medicine ward of Hospital of Nossa Senhora da Assunção of ULS Guarda EPE.

Materials and methods: The authors evaluated consecutively 103 elderly diabetic patients from February to December 2009 and compared them to a group of 115 non-diabetic elderly patients. The clinical tool was the Mini Nutritional Assessment (MNA) who stratifies nutritional state from 0 to 30 in: malnutrition (<17), malnutrition risk (17,5-23,5) and normal (>24). Statistical analysis was performed by SPSS 13.0 for Windows, when appropriate.

Results: The 103 elderly diabetic patients (59,2% female and 40,8% male) had a mean age of 81,55 ± 7,08 years. There was no statistical significant difference from the 115 non-diabetic control group (59,1% female, 40,9% male with a mean age of 83,27 ± 7,02 anos, p > 0,05). Mean MNA score in Diabetic elderly patients was 13,64 ±4,11 which was significantly lower than in the control group (16,50±4,46, p < 0,001). In Diabetic patients, 13,6% had a normal score evaluation at screening and did not need to follow MNA evaluation, 66 % were classified with malnutrition , 19,4 % with malnutrition risk and 1 % were normal (values of 40,9%, 27,8%, 23,5% e 7,8% respectively for control group, p<0,001).

Conclusion: This study suggests that malnutrition is more prevalent in elderly people with type 2 diabetes admitted to a medical ward for various reasons, which implies that they must be identified for specific nutritional intervention. There will be necessarily more studies to evaluate the causes and the complex relationship between type 2 diabetes and malnutrition in elderly patients.

N-3 fatty acids as phospholipids are superior over triacylglycerols in ameliorating hepatic steatosis in mice fed a high-fat diet

T. Jelenik[1], Z. Macek Jilkova[1], M. Rossmeisl[1], D. Medrikova[1], P. Janovska[1], P. Flachs[1], B. Kristinsson[2], G.G. Haraldsson[2], H. Svensen[3], I. Stoknes[3], M. Bryhn[4], J. Kopecky[1];
[1]Department of Adipose Tissue Biology, Institute of Physiology, AS CR, v.v.i., Prague, Czech Republic, [2]University of Iceland, Science Institute, Reykjavik, Iceland, [3]EPAX AS, Aalesund, Norway, [4]Silentia AS, Svelvik, Norway.

Background and aims: n-3 polyunsaturated fatty acids (PUFA), such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), could prevent development of obesity and insulin resistance. In this study, metabolic consequences of dietary n-3 PUFA supplemented to a high-fat diet either as phospholipids (PL) or triacylglycerols (TG) concentrates were studied in the obesity-prone C57BL/6J strain of mice.
Materials and methods: In the *Prevention* study, 3-mo-old male mice were fed *ad libitum* for 9 weeks either a corn oil-based high-fat diet (cHF; lipids ~35% wt/wt) or cHF-based experimental diets, matched for the total EPA and DHA content (3.15% wt/wt), in which part of dietary lipids (corn oil) was replaced by the EPA and DHA concentrates (EPAX a.s., Aalesund, Norway) in the form of either TG-concentrate (EPAX 1050 TG; 60% EPA+DHA wt/wt) or novel PL-concentrate (27% EPA+DHA wt/wt). In the *Reversal* study, obesity was induced by cHF feeding for 4 mo prior to dietary treatments by either TG- or PL-concentrates. Obese mice were then subjected to one of the following treatments: 1) cHF diet; 2) cHF and metformin (2 g/kg diet; cHF+M diet); 3) cHF+M and TG-concentrate (cHF+M+TG diet); 4) cHF+M and PL-concentrate (cHF+M+PL diet). Markers of glucose and lipid homeostasis, glucose tolerance (AUC), hepatic steatosis, adipocyte hypertrophy and adipose tissue inflammation were analyzed.
Results: In the *Prevention* study, the concentrates did not affect weight gain or adiposity, while reducing plasma NEFA (cHF, 0.44 ± 0.04 vs. TG-concentrate, 0.30 ± 0.02 vs. PL-concentrate, 0.27 ± 0.04 mmol/l; $p \leq 0.01$ cHF vs. either concentrate). PL-concentrate more effectively ($p<0.05$ vs. cHF) reduced plasma TG (cHF, 1.12 ± 0.13 vs. TG-concentrate, 0.91 ± 0.13 vs. PL-concentrate, 0.71 ± 0.13 mmol/l) and increased high-molecular weight adiponectin (cHF, 0.60 ± 0.11 vs. TG-concentrate, 0.88 ± 0.10 vs. PL-concentrate, 0.93 ± 0.09 A.U.). Only PL-concentrate ($p<0.01$) improved glucose tolerance during a 3-hr tolerance test (AUC: cHF, 2221 ± 78 vs. TG-concentrate, 2299 ± 84 vs. PL-concentrate, 1831 ± 84 mmol), and prevented hepatic lipid accumulation (cHF, 41 ± 7 vs. TG-concentrate, 36 ± 4 vs. PL-concentrate, 27 ± 4 mg/g tissue). In the *Reversal* study, both concentrates reduced abdominal fat depot, plasma TG, NEFA and cholesterol, and induced adiponectin. However, hepatic steatosis was more effectively reduced by PL-concentrate (cHF, 212 ± 28 vs. cHF+M, 160 ± 17 vs. cHF+M+TG, 83 ± 15 vs. cHF+M+PL, 41 ± 4 mg/g tissue; $p<0.001$ cHF+M vs. either treatment), and only PL-concentrate ($p<0.05$ vs. cHF+M) reduced adipocyte hypertrophy (cHF, 5532 ± 553 vs. cHF+M, 5961 ± 381 vs. cHF+M+TG, 5195 ± 349 vs. cHF+M+PL, 4433 ± 127 μm^2).
Conclusion: As compared to TG, dietary n-3 PUFA administered as PL exert a number of superior effects on obesity-associated metabolic disorders. The PL-concentrate was especially effective in reducing hepatic lipid accumulation and adipocyte hypertrophy associated with high-fat feeding. Thus, the use of n-3 PUFA as PL might be a preferred way of dietary supplementation to help prevent or even reverse hepatic steatosis associated with obesity and insulin resistance.

The effects of omega-3 polyunsaturated fatty acids on cardiometabolic parameters and oxidative stress after 1-year administration in metabolic syndrome patients

A.D. Dragomir[1], G. Radulian[2], E.D. Rusu[1], S. Dragan[3], D. Cheta[2];
[1]Healthy Food Foundation, Bucharest, [2]University of Medicine "Carol Davila", Bucharest, [3]University of Medicine, Timisoara, Romania.

Background and aims: To observe if one year administration of a diet containing omega-3 PUFA supplements vs. baseline diet recommended to patients with metabolic syndrome has a significant impact on oxidative stress, atherosclerosis progression and metabolic parameters.
Materials and methods: A total of 270 patients with metabolic syndrome (MS) according to IDF criteria, aged 61±6.8 years, without clinical evidence of atherosclerosis were allocated to 2 groups, matched by sex, age and weight: group A (140 patients) - diet according to ESC/EASD recommendations and individual needs; group B (130 patients) - the same diet + capsules of fish oil (1,0 g eicosapentanoic acid, 1,0 g docosahexanoic acid and 0,1 g α-tocopherol acetate). Body fat mass (BFM) and body fat percent (%BF) were measured by bioimpedance analysis (BIA) using InBody 3.0 Analyzer. Fasting plasma glucose, HbA1c, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, plasma insulin, adiponectin and leptin were measured according to standard procedures. Insulin resistance was measured using HOMA-IR index. Oxidative stress was assessed using FormOx systems monitor on a blood drop. The progression of atherosclerosis was determined by measuring intima-media thickness (IMT) at commune carotid artery (ACC). The patients were evaluated at baseline, after 6 months and after 1 year.
Results: Baseline characteristics were similar between groups. After 6 months, omega-3 supplements determined a significant improvement of metabolic parameters, decrease of oxidative stress and a statistically significant increase in adiponectin levels (from 9.46 ± 2.76 to 10.86 ± 2.68). Mean BMI, mean %BF, mean BFM and mean waist-to-hip ratio (WHR) were significantly lower in group B vs. group A (BMI- 29.1 vs 31.12 kg/m^2; %BF - 27.48 vs 30.48; BFM - 26.78 vs 29.42 kg; WHR - 1.02 vs 1.07). BMI was statistically correlated with BFM ($p<0.0001$) and %BF ($p<0.0001$). Intima-media thickness (IMT) was significantly decreased in group B (IMT in left ACC - 0.610 ± 0.06 vs. 0.621 ± 0.071 mm p=0.002; IMT in right ACC - 0.593 ± 0.074 vs. 0. 612 ± 0.068). Considering the results at 6 months comparing with those at 1 year, all the parameters considered in the study were significantly improved (Table 1). IMT was correlated with %BF ($p<0.0001$), WHR (p=0.002), leptin values ($p<0.001$), adiponectin values ($p<0.001$), leptin/adiponectin ratio ($p<0.001$) and oxidative stress ($p<0001$). The decrease of oxidative stress was correlated with increased HDL-cholesterol levels ($p<0.05$), %BF ($p<0.0001$) and WHR ($p<0.001$).
Conclusion: Omega-3 PUFA enriched diets bring metabolic parameters closer to target values, thus lowering cardiovascular risk of MS patients. Also, oxidative stress is decreased, underlying the role of omega-3 in the delay of endothelial cells damage.

Table 1

Parameters	Group B - at 6 months	Group B - at 1 year	P value
Total cholesterol (mg/dl)	198 ± 18.9	186 ± 16.5	P<0.001
HDL-cholesterol (mg/dl)	55 ± 12	58 ± 9	P<0.0001
Triglycerides (mg/dl)	132 ± 58	120 ± 43	P=0.012
Fasting Plasma Glucose (mg/dl)	110 ± 14	107 ± 9	P<0.05
FormOx (Fort Units)	268 ± 76	258 ± 81	P<0.001
IMT - right ACC	0.610 ± 0.06	0.598 ± 0.082	P<0.001
IMT - left ACC	0.593 ± 0.074	0.589 ±0. 063	P<0.05
%BF	27.48 ± 2.8	25.92 ± 1.6	P=0.016

Metabolic inflexibility to carbohydrates in dietary obese mice: improvement by combination treatment with n-3 polyunsaturated fatty acids and calorie restriction

K. Bardova, P. Janovska, P. Flachs, D. Medrikova, V. Kus, Z. Macek Jilkova, T. Jelenik, M. Rossmeisl, J. Kopecky;
Department of Adipose Tissue Biology, Institute of Physiology, AVCR, v.v.i., Prague, Czech Republic.

Background and aims: Metabolic flexibility is the capacity for the organism to adapt fuel oxidation to fuel availability and it is usually impaired in obese, insulin-resistant subjects. In this study, we attempted to validate the use of intragastric glucose gavage and indirect calorimetry (INCA) for the measurement of metabolic flexibility to carbohydrates in lean and dietary obese C57BL/6J mice. In addition, we used this approach to assess the effects of a combination treatment by n-3 polyunsaturated fatty acids (PUFA) and 10% calorie restriction (CR) on metabolic flexibility in mice fed a high-fat diet.
Materials and methods: Female C57BL/6J mice were fed either a standard chow (STD) or corn oil-based high-fat diet (cHF; lipids ~35% wt/wt) from

the weaning (4 wk of age) until 7 mo of age (n = 6-9). Metabolic flexibility was assessed as a maximal change in respiratory quotient (ΔRQ) measured by INCA during a 4-hr period following a glucose load (0.45 ml of 50% D-glucose) administered by intragastic gavage to overnight (~12 hr) fasted animals. In the second experiment, 3-mo-old male C57BL/6J mice were habituated for 2 wk to the cHF diet, followed by differential dietary treatments (n = 8-9) for 5 wk: (1) cHF, *ad libitum*; (2) cHF with n-3 PUFA concentrate (EPAX 1050TG; EPAX, a.s., Lysaker, Norway) replacing 15% of dietary lipids, *ad libitum* (cHF+F); (3) cHF, 10% CR (cHF+CR); or (4) cHF+F, 10% CR (cHF+F+CR). Changes in plasma NEFA in response to fasted to fed transitions were also analyzed.

Results: In the first experiment, cHF feeding for 6 mo induced a weight gain of 31.7 ± 2.5 as compared to a gain of 10.8 ± 0.5 g in the STD mice (body weight: cHF, 45.8 ± 2.4 vs. STD, 25.0 ± 0.6 g; $p<0.001$). Although there were no differences between cHF and STD mice in RQ following overnight fasting (cHF, 0.746 ± 0.010 vs. STD, 0.773 ± 0.008; p=0.057), cHF-fed mice showed a ~2-fold lower increase in RQ in response to the glucose load as compared to STD controls (ΔRQ; cHF, 0.062 ± 0.006 vs. STD, 0.120 ± 0.010; $p<0.001$), suggesting impaired metabolic flexibility. In the second experiment, compared with cHF mice, all the treatments tended to prevent body weight gain (cHF > cHF+F > cHF+CR > cHF+F+CR), while a significant reduction was found only in mice subjected to the combination treatment (cHF, 28.7 ± 0.7 vs. cHF+F+CR, 25.8 ± 0.4 g; $p<0.001$). This treatment was also the most effective in elevating RQ in response to glucose (ΔRQ; cHF, 0.086 ± 0.002 vs. cHF+F, 0.095 ± 0.006 vs. cHF+CR, 0.096 ± 0.005 vs. cHF+F+CR, 0.107 ± 0.006; $p<0.05$ cHF vs. cHF+F+CR). At the same time, cHF+F+CR induced a most prominent decrease in plasma NEFA following fasted (cHF, 0.89 ± 0.05 vs. cHF+F+CR, 1.13 ± 0.04 mmol/l) to fed (cHF; 0.59 ± 0.09 vs. cHF+F+CR, 0.43 ± 0.04; $p<0.001$ cHF vs. cHF+F+CR mmol/l) transition, while the other treatments were less effective.

Conclusion: Metabolic inflexibility to carbohydrates could be demonstrated using intragastric glucose gavage and INCA in dietary obese mice. Combination treatment using n-3 PUFA and 10% CR preserved metabolic flexibility better than any of these treatments applied separately.

Cross-linked dairy protein attenuates postprandial glucose and insulin levels and increases fullness in healthy young men

K.-H. Herzig[1], K.R. Juvonen[2], L.J. Karhunen[2], E. Vuori[1], M. Lille[3], T. Karhu[1], A. Jurado Acosta[1], D. Laaksonen[4], H. Mykkanen[2], L.K. Niskanen[4], K. Poutanen[3];
[1]Dept of Physiology, Medical School, Institute of Biomedicine, University of Oulu, [2]Department of Clinical Nutrition, Food and Health Research Centre, University of Eastern Finland, [3]VTT, Technical Research Centre of Finland, [4]Department of Medicine, Kuopio University Hospital, Finland.

Background and aims: Food induces many signals in the gastrointestinal tract, important for digestion, satiety and further systemic responses. The properties of foods are determined by their chemical composition and physical properties. Protein has the highest satiety value of among the different macronutrients. Furthermore, the textural properties of a single protein can be tailored by cross-linking enzymes e.g. transglutaminase (Tg). However, little is known about the effects of modified protein structures on these responses. Our aim was to examine the effects of intact and transglutaminase (TG) cross-linked dairy protein on postprandial hormonal, metabolic and appetitive responses.

Materials and methods: The study had a randomized repeated-measures crossover design. All participants tested each test product with a minimum of 2 d separating the individual test days. Eight healthy males (24.0±0.82 y, 23.3±0.5 BMI kg/m^2) consumed with 400 ml water isocaloric (850 kJ) and isovolumic (400 ml) test product containing either 50 g whey (Wh), casein (Cas) or casein protein cross-linked with transglutaminase (Cas-TG) in a randomized order. Blood samples were drawn for plasma glucose, insulin, CCK, GLP-1 and PYY analysis for 240 min. Appetite ratings were assessed at concomitant time points using visual analogue scales.

Results: Glucose levels significantly decreased in the first hour and returned close to baseline at the end of sampling at 240 min. Cas and Wh were more potent in lowering glucose levels than Cas-Tg. Release of insulin, GLP-1, PYY and CCK differed significantly in response to the three protein meals, with the highest insulin release 30 min after Wh. The insulin response to Cas-Tg was attenuated and peaked at 60 min. GLP-1 peaked at 15 - 30 min after Wh and 60 min after Cas, whereas the response to Cas-Tg was attenuated. PYY peaked after 30 - 60min, with the highest levels after Cas and the lowest after Cas-Tg. CCK increased similarly in the first 15 min after the Wh or Cas meal, while the release after Cas-Tg was lower, but more sustained. The feeling of fullness was the strongest after the Cas-TG compared to Cas and Wh.

Conclusion: Cross-linked milk protein attenuates the release of the GI hormones affecting plasma glucose and insulin levels and enhances fullness. The modification of protein texture could thus offer a tool for optimizing the postprandial glucose and insulin metabolism and postprandial appetite and thereby promote weight management and glycaemic control in obese and DM 2 patients.

Effects of different types of meal on the expression on oxidative mitochondrial genes in skeletal muscle of healthy subjects

A.A. Turco[1], M. Guescini[2], V. Valtucci[1], C. Colosimo[1], V. Stocchi[2], G. Riccardi[1], B. Capaldo[1];
[1]Department of Clinical and Experimental Medicine, Federico II, University, Naples, [2]Institute of Biological Chemistry, University of Urbino "Carlo Bo", Urbino, Italy.

Background and aims: Recent studies have shown an impaired mitochondrial oxidative capacity in skeletal muscle of individuals with insulin resistance, suggesting that mitochondrial dysfunction may be a primary, genetically determined defect. There is also evidence that mitochondrial dysfunction may be a consequence of adverse environmental factors, such as sedentary lifestyle and over nutrition. To evaluate the impact of acute administration of different dietary fat on the expression of muscle mitochondrial genes regulating replication and function in healthy subjects.

Material and methods: Six healthy subjects (3F/3M; age 29±3 years; BMI 25.0±3 Kg/m^2) received in a random order a test meal with the same energy content (970 Kcal) but different composition in macronutrients and quality of fat: Mediterranean meal (M) (Lipid 30% of which 6% saturated), SAFA meal (Lipid 67% of which 36% saturated) and MUFA meal (Lipid 63% of which 37% monounsaturated). At fast and after 180 min, a fine needle aspiration (FNA) was performed from the vastus lateralis muscle for determination of mithocondrial gene expression by quantitative PCR.

Results: M meal was associated with a significant increase ($p<0.05$) of transcription factor PPARs expression levels, whereas expression of regulator genes PGG1α and PGG1β remained substantially unchanged. No change was detected in the expression of COX5b, COX2 and GLUT 4 genes. After MUFA meal, no modification was observed in the expression of PPARs, but a significant increase of PGC1α (p=0.07) and PGC1β ($p<0.001$) gene expression was observed. COX5b e COX2 gene expression remained unchanged whereas GLUT4 gene expression increased significantly ($p<0.05$). After SAFA meal, PGG1α, PGG1β, and PPARs gene expression were unchanged whereas COX2 expression decreased by 38 % ($p<0.02$), COX5b decreased by 31% (p=0.07), and GLUT4 decreased by 11% ($p<0.05$).

Conclusion: The present data indicate that mitochondrial gene expression in skeletal muscle of healthy subjects can be modulated by acute changes of nutrient intake. Dietary fat have a differential impact on the gene transcriptional profile since saturated fat, but not monounsaturated, downregulate the expression of genes involved in glucose transport and substrate oxidation.

948

Dose-dependent anti-obesity and anti-diabetic effects of synbiotics in high-fat fed C57BL/6J mice

K. Berger, U. Andersson, C. Holm;
Experimental Medical Science, Lund University, Lund, Sweden.

Background and aims: We have recently shown that plants rich in polyphenols (with antioxidants and prebiotic effects) administered alone or together with the probiotic dietary bacteria Lactobacillus plantarum (Lp) exerts anti-obesity and anti-diabetic effects in HFD-fed C57BL/6J mice, a model of human obesity and insulin resistance. For instance, we observed an almost complete prevention of body weight gain, as an effect of decreased adiposity, in groups receiving the supplemented diets. In addition, we observed an inhibited inflammatory activity in mice receiving the combination of supplement. Based on these results where the dramatic effects were attained with relatively high polyphenol concentration, we here aim to evaluate the dose-response relationship for the studied plant-associated polyphenol, both in absence and presence of probiotic bacteria.

Materials and methods: C57BL/6J mice were fed high fat diet supplemented with different concentrations of plant-associated polyphenols (pph 0, 0.4, 2 and 4%) without or with Lactobacillus plantarum (Lp 3 x 10^9 cfu/ml drinking water) for 12 weeks. Body weight, body fat and metabolic blood parameters were registered throughout the study. Oral glucose tolerance (OGTT) was performed in the end of the study. At the time of sacrifice, plasma and tissues were collected.
Results: Supplement of the plant-associated polyphenol, without or with probiotics, decreased body weight gain (pph: 0%:10.2±0.4, 0.4%:9.7±0.7, 2%:7.8±0.5, 4%:5.8±0.4g, pph+Lp: 0%:10.5±1.5, 0.4%:10.0±0.8, 2%:9.4±1.2, 4%:5.7±0.5g) and adiposity (pph: 29.2±1.3, 28.7±1.5, 25.7±1.6, 20.4±0.8%, pph+Lp: 31.2±3.3, 31.3±2.2, 26.1±2.6, 17.7±0.7%) in a dose-dependent manner. Dose-dependent decrease was also observed in the liver weights (pph: 1.2±0.0.4, 1.2±0.05, 1.1±0.0.5, 0.9±0.03g, pph+Lp: 1.2±0.13, 1.0±0.06, 1.2±0.07, 0.8±0.04g), and more pronounced in mice receiving the combination of polyphenols and probiotics than in mice receiving polyphenols alone, indicating a synbiotic beneficial effect. Also, mice fed the combination of supplements showed decreased fasting plasma glucose (pph+Lp: 6.9±0.7, 5.9±0.4, 6.2±0.0.6, 4.6±0.2 mM) with increasing concentration of polyphenols, although only the highest concentration (4%) of polyphenols was significantly decreased compared to ctrl.
Conclusion: High-fat diet supplemented with different concentrations of a polyphenol-rich plant powder, without or with addition of probiotics, gives dose-dependent beneficial effects on body weight, adiposity and glucose control. The observed advantageous effects are more pronounced in the presence of Lactobacillus plantarum, indicating a synbiotic effect.

Effects of supplementation with red wine polyphenols on inflammation, mitochondrial function and oxidative stress muscle
K. Lambert, M. Coisy-Quivy, P. Sirvent, A. Sultan, C. Bisbal, J. Mercier, A. Avignon;
INSERM ERI 25, Montpellier, France.

Background and aims: The mechanisms responsible for skeletal muscle insulin resistance (IR) remain incompletely understood. However, chronic low-grade inflammation, oxidative stress and mitochondrial alterations have been suggested to take part in the development of IR. Recent studies have found that polyphenolic compounds found in red grape have interesting properties against IR. Thus, the aim of this study was to investigate the impact of a supplementation with phenolic compounds from red grape marc in a genetically modified mouse (CD4dnTGFbRII; TGF) presenting a chronic inflammation compared to C57BL/66 (CTL).
Materials and methods: 14 TGF mice and 16 CTL mice were randomized between a control group (placebo, PL) and a group supplemented with polyphenols (PP) administered in drinking water (50mg/kg/jour) for a period of 4 weeks. The mice were sacrificed and their muscles taken for the study of muscle inflammation (RT-PCR), oxidative stress (mitochondrial carbonylated proteins) and fiber size (atrophy marker). The mitochondrial respiration was measured on mitochondria isolated from skeletal muscle.
Results: In TGF mice, the PP decreased muscle atrophy by 20% (p<0,0001) without reducing the expression of mRNA of inflammation markers (TNFalpha, OAS1, OAS2). In CTL mice, the PP increased the amount of TNFalpha mRNA by 700% (p=0,001) and decreased fiber size by 12% (p<0,0001). In CTL and TGF mice, the PP supplementation decreased mitochondrial respiration (TGF mice: 387 ± 35 vs 276 ± 33 nmol O / min / mg prot; CTL mice 277 ± 38 vs 178 ± 41 nmol O/min / mg prot, comparison PL vs PP by Anova p=0,009) without changing the amount of ATP synthesized. We also observed a decrease in the level of carbonylated mitochondrial proteins with PP supplementation in both strains of mice (comparison PL vs PP by Anova p=0,03).
Conclusion: The PP supplementation decreased mitochondrial oxidative stress and improved mitochondrial function in muscle of inflammatory and control mice. They also reduced muscle atrophy in inflammatory mice. Paradoxally, the PP increased the markers of inflammation and decreased fiber size in CTL mice. Further research should be persued to evaluate the effects of PP on muscle mass preservation in inflammatory states.

Reduction of glycaemic index enhances levels of midregional-pro-atrial-natriuretic peptide: evidences for gut-heart-axis?
A.F.H. Pfeiffer[1,2], A. Ernst[3], M.O. Weickert[1,4], O. Pivovarova[1,2], A.M. Arafat[2,1], N.G. Morgenthaler[3], A. Bergmann[3], N.N. Rudovich[1,2];
[1]Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, Germany, [2]Endocrinology, Diabetes and Nutrition, Charité University Medicine Berlin, Germany, [3]B.R.A.H.M.S AG, Biotechnology Centre Berlin-Hennigsdorf, Germany, [4]Warwickshire Institute for the Study of Diabetes, Endocrinology and Metabolism, Coventry, United Kingdom.

Background and aims: Reduction of glycemic index is an effective strategy for prevention of hypertension and CVD events in the subjects with metabolic syndrome and T2DM. Atrial natriuretic peptide (ANP) is a potent natriuretic and vasorelaxant hormone that is secreted mainly by cardiomyocytes and plays contributory roles in cardiovascular homeostasis. In the subjects with Metabolic Syndrome (MS) circulating level of N-terminal natriuretic peptides are decreased for unknown reason. The midregional-pro-atrial-natriuretic peptide (MR-proANP) is a stabile fragment of the ANP precursor proANP, which is co-secreted with mature ANP from cardiomyocytes. We hypothesized that reduction of glycemic index by alpha-glucosidase inhibitor acarbose may modulate MR-proANP levels.
Materials and methods: Subjects with MS (n=28) were studied in the double blind, placebo controlled, crossover intervention study. Interventions with acarbose (3x100 mg/d) or placebo for 12 weeks (with a respective 12-week washout period) were performed. Changes in MR-proANP, postprandial glucose/insulin responses during liquid meal challenge test, body weight, and insulin sensitivity in the euglycemic clamp were assessed. Furthermore, in a cohort of normotensive non-diabetic subjects (n=46), the effect of insulin application on MR-proANP was analyzed during a hyperinsulinemic-euglycemic clamp.
Results: Fasting MR-proANP increased after 12 weeks of acarbose treatment (p=0.001). Acarbose decreased postprandial insulin and glucose concentrations (p=0.0001 and p = 0.024, respectively). Changes in MR-proANP levels correlated negatively with changes in postprandial insulin (r= -0.53, p<0.0001). No effects on body weight and insulin sensitivity were observed. Exogenous insulin suppresses plasma levels of MR-proANP (p<0.001).
Conclusion: Reduction of glycemic index by acarbose increases MR-proANP levels in subjects with MS. Moreover modulation of insulin levels has a strong effect on circulating MR-proANP. These observations provide a novel link between postprandial metabolism and hormonal heart action.

Rose hip exerts anti-diabetic effects via a mechanism involving downregulation of the hepatic lipogenic program
U. Andersson[1], E. Henriksson[1], K. Ström[1], J. Alenfall[2], O. Göransson[1], C. Holm[1];
[1]Experimental Medical Science, [2]Probi AB, Lund, Sweden.

Background and aims: In the recent decades there has been a dramatic increase in the prevalence of obesity and type 2 diabetes worldwide. Both type 2 diabetes and obesity are strongly associated with non-alcoholic fatty liver disease, the most common liver disease worldwide. Rose hips are a rich source of antioxidants such as ascorbic acid, phenolic compounds and carotenoids. Recently it was shown that administration of an acetone extract from fruit and seeds from *Rosa canina* prevented body weight gain in mice fed a normal chow diet. The aim of this study was to explore the beneficial metabolic effects of rose hip in greater detail and to elucidate some of the mechanisms underlying the observed anti-diabetic effects. We used the high-fat fed C57BL/6J mouse which is a model for obesity, impaired glucose tolerance and early type 2 diabetes.
Materials and methods: Long-term metabolic effects were investigated in this mouse model following administration of powdered rose hip together with high-fat diet to lean mice. Parameters related to obesity and glucose tolerance were monitored, and livers were examined for lipids and expression of genes and proteins related to lipid metabolism and gluconeogenesis.
Results: A supplement of rose hip was capable of preventing the increase in body weight imposed by a high-fat diet in the C57BL/6J mouse (7.1±0.4 vs. 17.1±1.1g, p<0.001). The decreased body weight gain mirrored a lower body fat content, measured by dexa-scan technique. Lower basal levels of in-

sulin (91±15 vs. 351±99 pM, p<0.001) and glucose (5.5±0.3 vs. 9.4±0.5 mM, p<0.001) together with a reduced insulin response (AUC; 132531±19516 vs. 40427±7143, p<0.001) following an OGTT showed improved glucose tolerance in mice fed a supplement of rose hip compared to control mice. Hepatic triacylglycerol accumulation was reduced in mice fed rose hip compared to control (26±3 vs. 66±5 mg/g liver, p<0.001) and the expression of several lipogenic proteins was downregulated, whereas AMPK and other proteins involved in fatty acid oxidation were unaltered. Further, rose hip intake lowered plasma cholesterol (4.9±0.1 vs. 6.6±0.3, p<0.001) via a mechanism not involving altered gene expression of sterol regulatory element binding protein 2 and HMG-CoA reductase.
Conclusion: Taken together, these data show that a dietary supplement with rose hip prevents the development of a diabetic state in the C57BL/6J mouse. Downregulation of the hepatic lipogenic program appears to be at least one mechanism underlying the anti-diabetic effect of rose hip.

Vegetarian diet improves plasma concentrations of adipokines and oxidative stress markers more than conventional diabetic diet in subjects with type 2 diabetes
H. Kahleova[1], M. Matoulek[2], H. Malinska[1], O. Oliyarnik[1], L. Kazdovā[1], T. Pelikánová[1];
[1]Diabetes Centre, Institute for Clinical and Experimental Medicine, [2]3rd Internal Clinic of Endocrinology and Metabolism, General University Hospital, Prague, Czech Republic.

Background and aims: Trials using vegetarian diet in subjects with type 2 diabetes (T2D) have shown greater improvement in HbA1c compared to conventional diabetic. We sought to investigate the effect of vegetarian diet on plasma concentrations of adipokines and oxidative stress markers.
Materials and methods: Subjects with T2D (n=74) were randomly assigned to experimental group (EG, n=37) following vegetarian diet or control group (CG, n=37) following conventional diabetic diet with the same caloric restriction. Participants were examined at baseline, 12 weeks of diet intervention and 24 weeks (second 12 weeks of diet were combined with aerobic exercise). Plasma concentrations of chosen adipokines and oxidative stress markers were measured using commercial kits.
Results: 43% of EG and 5% of CG participants reduced diabetes medication. Body weight decreased by 6.2 kg in EG and by 3.2 kg in CG (interaction between group and time p=0.001). Plasma concentrations of vitamin C increased in EG by 22% (p=0.002; group x time p=0.002). Superoxide dismutase increased in EG by 49% (p<0.001), whereas in CG it decreased by 30% (p<0.001; group x time p<0.001). Catalase increased in both groups (p<0.001 for EG and p=0.01 for CG). TBARS decreased in both groups (p<0.001 for both groups). Reduced glutathione increased in EG by 27% (p=0.02), whereas in CG it decreased by 11% (p=0.05; group x time p<0.001). Glutathione reductase decreased in EG by 42% (p<0.001) while glutathione peroxidase increased in CG by 20% (p<0.001) and glutathione transferase increased in both groups, more in CG (by 59% vs. 14% in EG; group x time p=0.003). Plasma concentrations of total adiponectin increased in EG by 19% (p=0.05; group x time p=0.02). HMW adiponectin increased in EG by 15% (p=0.02; group x time p=0.05). Resistin increased by 24% in CG (p=0.01; group x time p=0.005). Leptin decreased by 35% in EG (p=0.02; group x time p=0.05).
Conclusion: Vegetarian diet led to greater weight loss and reduction of diabetes medication and to greater improvement in plasma levels of adipokines and oxidative stress markers. Vegetarian diet could be a more convenient alternative in treatment of T2D.

PS 88 Initiating and intensifying insulin therapy

953

Negative attitudes towards insulin treatment in type 2 diabetes seems to be a rather temporal and benign phenomenon: Results of an observational longitudinal study
N. Hermanns[1], B. Kulzer[1], M. Mahr[1], S. Skovlund[2], T. Haak[1];
[1]Research Institute of Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, Germany, [2]Novo Nordisk AS, Bagsværd, Denmark.

Background and aims: Cross sectional findings indicate that negative attitudes towards insulin therapy are rather frequent in type 2 diabetes. These attitudes may be based on beliefs that the need for insulin therapy indicates a higher severity of diabetes and proves a failure of successful diabetes self-management. Worries about painful injections and the risk of hypoglycaemia or weight gain are also common. These negative attitudes may be one reason for the delay of insulin treatment initiation. In this observational longitudinal study with a three month follow-up the course of negative attitudes towards insulin treatment was analysed in three different groups of type 2 diabetic patients facing an intensification of diabetes treatment.
Materials and methods: The first subgroup was on insulin therapy at baseline (n = 57; age 56.0 ±8.9, disease duration 12.7 ±7.2 yrs, HbA1c 8.5 ±1.6%) and remained on insulin at follow-up. Of an initial 73 insulin-naïve patients, 44 were switched to insulin therapy (group 2: age 58.1 ±6.8, disease duration 7.7 ±5.0 yrs, HbA1c 9.1 ±1.7%) and 29 patients remained on an oral regimen (group 3: age 52.7 ±10.7 yrs, disease duration 5.3 ±4.6 yrs, HbA1c 8.3 ±1.4%). Barriers towards insulin therapy were measured using the Insulin Treatment Appraisal Scale (ITAS). As generic instruments of health related quality of life patients completed also the Problem Areas of Diabetes Questionnaire (PAID), the WHO-5 Well-Being Scale (WHO-5), the Centre for Epidemiologic Studies Depression Scale (CES-D) and the Trait Version of the State Trait Anxiety Inventory (STAI) at baseline and at a three month follow-up.
Results: In the three month follow-up HbA1c improved in all three groups (7.7 ±1.2% vs. 7.1 ±1.1% vs. 6.7 ±1.7%). The course of negative appraisal of insulin therapy was significantly different in the 3 groups (p=-003): It increased in patients remaining on an oral regimen (51.2 ±12.2 to 53.6 ±12.3), whereas the ITAS score decreased in patients who switched to insulin (:49.2 ±9.8 to 46.2 ±9.9) and patients who remained on insulin (45.8 ±8.3 to 44.5 ±8.0). More generic psychological variables like diabetes related distress, trait-anxiety or well-being showed an improvement in all three groups, but no significant differences between the groups. In patients who switched to insulin therapy the depression score improved significantly (16.1±10.2 to 11.9±9.8) compared to the groups who remained on oral medication (11.7 ±8.2 to 10.8 ±7.9) respectively who remained on insulin therapy (CES-D: 17.8 ±10.9 to 16.4 ±9.8 p=,045).
Conclusion: In type 2 diabetic patients who switched to insulin therapy negative appraisal of insulin therapy was reduced to the level of type 2 diabetic patients already treated with insulin. Patients remaining on an oral regimen increased negative appraisal towards insulin therapy. In summary this study shows that negative appraisal of insulin treatment is modifiable by the initiation of insulin therapy, indicating that features of "psychological insulin resistance" are a benign, temporary phenomenon. More meth-odological robust randomized studies are needed to corroborate this result further.

Beginning insulin in people with type 2 diabetes mellitus in real life practice – 1-year results of the 4-year CREDIT Study
P. Home[1], B.J. Balkau[2], N. Danchin[3], E. Genestin[4], M. Marre[5], G. Vespasiani[6], R. Kawamori[7], N. Freemantle[8];
[1]Institute of Cellular Medicine – Diabetes, Newcastle University, United Kingdom, [2]INSERM CESP U1018, Villejuif, France, [3]Division of Coronary Artery Disease and Intensive Cardiac Care, Paris, France, [4]sanofi-aventis, Paris, France, [5]Université Paris, INSERM U695, France, [6]Diabetology and Metabolic Disorders Centre, San Benedetto Del Tronto (AP), Italy, [7]Department of Medicine, Juntendo University, Tokyo, Japan, [8]Department of Primary Care and General Practice, University of Birmingham, Edgbaston, United Kingdom.

Background and aims: CREDIT, a 314-centre, non-interventional study, investigates the effects of long-term glycaemic control with insulin treatment

on the risk reduction of cardiovascular events associated with type 2 diabetes mellitus (T2DM). Here, we present the 1-year findings of the CREDIT study in patients who initiated insulin at baseline.
Materials and methods: People with T2DM (n=3031) who had recently started insulin (basal, short-acting or premix insulin at the physician's discretion) were eligible for evaluation. Changes in therapy, metabolic control parameters and lipid profiles of 2734 people at baseline and at 1 year (9–18 months) after insulin initiation are described.
Results: Most people (75%) had the same insulin regimen at baseline and at 1 year (Table). Those starting with short-acting insulin regimen alone were more likely to have changed insulin regimen. Overall, the insulin dose increased from 19.7 ± 14.5 U/day at baseline to 34.4 ± 25.3 U/day at 1 year. Substantial reductions in HbA_{1c} (−1.8 %), fasting plasma glucose (FPG; −3.6 mmol/L) and postprandial PG (PPPG; −4.7 mmol/L) were observed; 32% of patients had HbA_{1c} <7.0 %. Symptomatic hypoglycaemia occurred in 20% of patients (2% experiencing at least one severe episode). Mean weight increased marginally by 1.7 ± 4.8 kg (from 80 ± 19 at baseline to 81 ± 18 at 1 year). LDL cholesterol levels were reduced slightly by −0.2 mmol/L (from 2.9 ± 0.9 to 2.7 ± 0.9 mmol/L) and triglycerides by −0.3 mmol/L (from 2.2 ± 2.4 to 1.8 ± 1.4 mmol/L). Mean HDL cholesterol levels were unchanged.
Conclusion: Although the results of the 1-year analysis of the CREDIT study are encouraging, the majority of patients remain above the HbA_{1c} target level of ≤7.0 % commonly advocated. The high FPG and PPPG levels indicate that there may be suboptimal insulin dose titration over the first year. In contrast to the substantial decrease in HbA_{1c}, the small decrease in LDL levels indicates that physicians focus on glucose control rather than on other aspects of secondary prevention.
Table

	Baseline (n=3031)	1-year follow-up (n=2734)	Change from baseline (n=2734)
Insulin regimen (%)*			
Basal	52	41	
Basal + short-acting	15	21	
Short-acting	7	3	
Premix	23	27	
Other	3	6	
HbA_{1c} (%)	9.5 ± 2.0	7.7 ± 1.4	−1.8 ± 2.1
FPG (mmol/L)	11.6 ± 3.7	7.9 ± 2.5	−3.6 ± 3.9
PPPG (mmol/L)	14.2 ± 4.6	9.6 ± 3.2	−4.7 ± 4.9

Fasting plasma glucose 6 to 12 weeks after starting insulin glargine predicts success in reaching HbA_{1c} ≤7.0% at weeks 24 to 28
D.M. Karl;
The Endocrine Clinic, PC, Portland, USA.

Background and aims: Adding insulin glargine, using a treat-to-target method, restores glycated hemoglobin A1C (A1C) to ≤7.0% for many patients with type 2 diabetes (T2DM) with inadequate glycemic control on oral agents, but some need further therapy to reach this goal. The purpose of this analysis was to assess whether early fasting plasma glucose (FPG) values predict glycemic control at week 24, and to help identify patients who may need prandial insulin after initiation of basal insulin.
Materials and methods: We analyzed patient-level data from 7 prospective, randomized controlled trials of insulin glargine with/without oral antidiabetic drugs in adults with T2DM with 24- or 28-week measurements and lab-measured FPG at week 6 or 8 and at week 12. These studies utilized strict, predefined insulin titration algorithms to achieve FPG concentrations ≤5.55 mmol/L.
Results: A total of 1036 patients (56% men; 81% white) had (mean±SD) age 56±10 y, duration of diabetes 8.4±5.9 y, baseline A1C 8.8%±1.0%. Mean A1C at endpoint was 7.03%±0.86%; mean FPG at endpoint was 6.67±1.9 mmol/L; 56% of patients reached A1C ≤7.0%. Mean FPG was 11.2±3.0 mmol/L at baseline, 7.33±2.2 mmol/L at week 6/8, and 6.77±1.9 mmol/L at week 12. Lower FPG at baseline was associated with lower A1C at week 24 (r=0.169, P<0.0001), but this correlation was stronger at week 6/8 (r=0.319, P<0.0001) and week 12 (r=0.317, P<0.0001). The figure shows percentage of patients reaching A1C ≤7.0% after having FPG in various ranges at baseline, week 6/8, and week 12. Patients with FPG ≥8.88 mmol/L at baseline had a likelihood of reaching A1C ≤7.0% similar to that of the whole population (55% vs 56%), but just 37% of those in this range at week 6/8 and 35% at week 12 did so. However, patients with FPG <8.88 mmol/L vs ≥8.88 mmol/L at week 12 had greater rates of symptomatic hypoglycemia (64.9% vs 51.8%). Laboratory FPG measurements correlated strongly with values self-measured at home (r=0.778, P<0.0001).
Conclusion: 1) Even a single FPG measurement (by laboratory or at home) can help identify persons starting insulin glargine who may need prandial therapy as well; 2) a value ≥8.88 mmol/L between weeks 6 and 12 indicates reaching target A1C ≤7.0% is unlikely and calls for individualized attention.

956

Basal supported oral therapy (BOT) and risk of transition to intensified regimens: a retrospective cohort study
R. Quinzler[1], F.-W. Dippel[2], M. Ude[3], A. Franzmann[1], K. Schuessel[1], S. Feldt[1], K. Leuner[3], W.E. Mueller[3], M. Schulz[1,3];
[1]GIDE - German Institute for Drug Use Evaluation (DAPI), Eschborn, [2]Sanofi-Aventis Deutschland GmbH, Berlin, [3]Department of Pharmacology, Goethe-University, Frankfurt at Main, Germany.

Background and aims: After failure of oral antidiabetic drugs (OAD), treatment with long acting insulin plus oral antihyperglycaemic agents (basal supported oral therapy, BOT) is preferably recommended in type 2 diabetic (T2D) patients according to the consensus statement of the American Diabetes Association (ADA) and the European Association for the Study of Diabetes (EASD). We aimed to assess the persistence of T2D patients starting a BOT with either insulin glargine (GLA) or NPH insulin (NPH) until modification of insulin therapy.
Materials and methods: A retrospective cohort study was performed using claims data for ambulatory prescriptions within the German statutory health-insurance scheme, based on a representative sample of more than 80 % of community pharmacies. Patients on BOT with either GLA or NPH between 01/2003 and 12/2006 were included and followed up until 12/2007. Persistence was defined as the duration of time from initiation of BOT with GLA or NPH until modification of insulin therapy, with either premixed insulin (CT), bolus insulin alone (SIT) or bolus insulin added to basal insulin (ICT). Univariate and multivariate proportional hazards models were used to compare both cohorts.
Results: In total, 97,976 patients (61,053 GLA and 36,923 NPH) were included. Altogether, 44.1 % of GLA patients and 48.7 % of NPH patients modified initial BOT. On average, these patients stayed 373 days on BOT with GLA and 305 days on BOT with NPH (incidence rate per 100 person-years: 25.8 vs. 33.4). During the observation period 23.7 % of the patients switched to ICT, 17.6 % to CT, and 4.5 % to SIT. The risk of switching from BOT to one of these intensified insulin regimens was significantly higher for NPH compared to GLA patients (HR 1.25, 99 % CI 1.22-1.28). After adjustment for predefined covariables i.e., type of physician, region, insurance status, health insurance company, comedication, number of OADs, dose of basal insulin, the risk for NPH patients remained significantly higher (HR 1.17, 99 % CI 1.14-1.20).
Conclusion: T2D patients under BOT with GLA remain significantly longer compared to NPH before they have to be switched to more intensified regimens. This might also be of economic importance, since BOT causes less resource consumption than CT, SIT or ICT regimens as has been shown by other investigators.

The STEPwise™ randomised, controlled, 48-week trial: intensifying treatment with stepwise addition of prandial insulin aspart, based on largest prandial glucose increment or largest meal, to once-daily basal insulin detemir in subjects with type 2 diabetes
K. Hermansen[1], S. Kumar[2], H. Mersebach[3], A.L. Svendsen[3], L. Meneghini[4];
[1]Aarhus University Hospital, Denmark, [2]Warwick University, United Kingdom, [3]Novo Nordisk A/S, Copenhagen, Denmark, [4]University of Miami Miller School of Medicine, United States.

Background and aims: Adding bolus insulin doses step by step is one approach for intensifying treatment in patients on basal insulin when glycaemic

control is no longer maintained. The aim of this randomised, controlled, parallel-group, open-label, 48-week trial (STEPwise™) was to compare the effect on glycaemic control and safety endpoints of sequential addition of prandial insulin aspart (IAsp) to: (a) largest perceived meal (SimpleSTEP); or (b) meal with the largest post-prandial glucose increment (ExtraSTEP).
Materials and methods: 296 subjects with type 2 diabetes inadequately controlled on basal insulin+OADs (mean age 58.3 yrs; mean HbA_{1c} 8.8%; mean diabetes duration 12.3 yrs) underwent a 12-week run-in and were transferred to once-daily bedtime insulin detemir with continuation of their previous stable pre-trial OAD regimen and optimisation of basal insulin doses. Subjects with HbA_{1c} ≥7% after run-in were randomised to one of the two groups, and sulphonylureas were discontinued. Bolus insulin titration was based on pre-meal glucose values for SimpleSTEP and post-meal glucose values for ExtraSTEP. After 12 weeks' treatment with the 1-IAsp regimen (Period 1), subjects not at HbA_{1c}<7% received a second IAsp titrated bolus at the next largest meal or uncovered meal with largest post-prandial glucose increment for an additional 12 weeks (Period 2); subjects with HbA_{1c} <7% continued with one IAsp injection. At 24 weeks, subjects with HbA_{1c} ≥7% received IAsp at a second/third meal and subjects with HbA_{1c} <7% continued on the 1- or 2-IAsp regimens for 12 more weeks (Period 3).

	SimpleSTEP (*n*=150)			ExtraSTEP (*n*=146)			End of trial estimated difference, 95% CI, *p*-value
Efficacy [mean (SE)]	Period 1	Period 2	Period 3	Period 1	Period 2	Period 3	
HbA_{1c} (%)	8.3 (0.06) (End of run-in: 8.7%)	7.8 (0.08)	7.6 (0.08)	8.4 (0.07) (End of run-in: 8.9%)	7.9 (0.08)	7.9 (0.08)	0.06 [-0.17, 0.29], *p*=0.606
FPG (mmol/L)	8.2 (0.26)	7.7 (0.25)	7.8 (0.26)	7.9 (0.25)	7.6 (0.25)	7.5 (0.26)	-0.27 [-0.99, 0.44], *p*=0.456
Weight change trial end (kg) [mean (SD)]	2.7 (3.9)			2.0 (3.8)			-0.67 [-1.60, 0.27], *p*=0.162

Results: At study end, both groups showed significant improvements in HbA_{1c} (~1.2%) with no difference between regimens. HbA_{1c} decreased by ~0.5% in Period 1, by a further ~0.5% in Period 2, and by ~0.2% in Period 3 in both groups. The overall rate of hypoglycaemia was low.
Conclusion: Improvement in glycaemic control with a low risk of hypoglycaemia can be achieved by the stepwise addition of insulin aspart to insulin detemir based on perceived meal size or measured post-prandial glucose increments.

Stepwise intensification of prandial insulin versus basal–bolus insulin therapy in patients with type 2 diabetes mellitus
D. Raccah[1], T. Haak[2], D. Huet[3], L. Monnier[4], J.S. Ramon[5], D. Robertson[6], P. Labard[7], A. Penfornis[8], OSIRIS Study Group;
[1]Hôpital Sainte Marguerite, Marseille, France, [2]Diabetes Zentrum, Bad Mergentheim, Germany, [3]Centre Hospitalier Saint Joseph, Paris, France, [4]Hôpital Lapeyronie, Montpellier, France, [5]Ciutat Sanitaria i Universitaria de Bellvitge, Barcelona, Spain, [6]Sandwell Medical Research, West Bromwich, United Kingdom, [7]sanofi-aventis, Paris, France, [8]CHU Hôpital Jean Minjoz, Besançon, France.

Background and aims: Insulin therapy intensification is important for patients with poorly controlled type 2 diabetes mellitus (T2DM). This international, randomized, parallel-group, non-inferiority study compared stepwise addition of prandial insulin with a basal–bolus regimen.
Materials and methods: A total of 811 patients (mean ± standard deviation [SD] age: 58.6 ± 8.9 years) with T2DM poorly controlled on basal insulin (HbA_{1c} 9.1 ± 1.4%; fasting plasma glucose [FPG] 9.7 ± 3.3 mmol/L [174 ± 59 mg/dL]) were switched to insulin glargine (GLAR) for 6 months, and continued oral therapy. At 6 months, mean GLAR dose was 36 U/day and mean HbA_{1c} was 8.3%. Patients with HbA_{1c} >7% and FPG <6.7 mmol/L (<120 mg/dL) (n=476) were then randomized to: Group 1) GLAR + metformin (MET) + 3× insulin glulisine (GLU); Group 2) GLAR + MET + 1–3× GLU; or Group 3) GLAR + MET + sulfonylurea + 1–3× GLU for 12 months. Patients in Group 1 received GLU at each meal; patients in Groups 2 and 3 injected GLU at the meal with the highest postprandial plasma glucose (PPPG), with two further doses added at Months 4 and 8 if HbA_{1c} was >7% (target PPPG 6.1–8.9 mmol/L [110–160 mg/dL]). Initial GLU dose was half the meal PPPG and titrated according to an algorithm based on the PPPG. Non-inferiority of Group 2 to Group 1 was concluded if the 95% confidence interval (CI) upper limit for the HbA_{1c} difference was ≤0.4%.
Results: The adjusted difference of Group 2 versus Group 1 for the per-protocol population (PP; primary analysis) crossed the non-inferiority margin (0.228 [95% CI: −0.018, 0.473]) but did not for the intent-to-treat population (ITT; secondary analysis; 0.122 [95% CI: −0.114, 0.358]). In both the PP and ITT, Group 1 was not superior to Groups 2 or 3 (Table). At endpoint, the GLAR dose was similar in all three groups with mean doses of 37, 40 and 40 U/day for Groups 1, 2 and 3, respectively. The mean GLU dose at endpoint was 29, 20 and 17 U/day, respectively; 33 and 40% of patients remained on one GLU injection in Groups 2 and 3, respectively. The incidence of symptomatic hypoglycaemia was highest in Group 3 and lowest in Group 2, although between-group differences were not significant (Table). Mean change in body weight was slightly increased in all three groups but the increase was significantly lower in Group 2 compared with Group 1 (Table).
Conclusion: Stepwise intensification of GLU added to GLAR showed efficacy similar to a basal–bolus approach with less symptomatic hypoglycaemia and significantly less weight gain, although non-inferiority was not achieved.

Premeal injection of rapid-acting insulin reduces postprandial glycaemic excursions, a randomised controlled trial
Y.M. Luijf, A.C. van Bon, J.B.L. Hoekstra, J.H. DeVries;
Internal Medicine, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: To assess the effect of three premeal timings of rapid-acting insulin on postprandial glucose excursions in patients with CSII treated type 1 diabetes.
Materials and methods: 10 subjects (3 females and 7 males) with T1DM participated. Mean (± SD) age was 45.5 ± 12.09 years, HbA1c 8.55 ± 1.50%, duration of diabetes 23.8 ± 7.81 years and duration of CSII therapy 8.5 ± 6.10 years. Patients were served an identical breakfast on three study days. Insulin aspart was randomly administered at 30, 15 or 0 minutes before the meal. All patients started the study with admission blood glucose between 3.5 and 7.8 mmol/L. Blood was sampled for glucose determination from one hour before the meal until four hours after.
Results: The area under the curve was significantly lower in the -15 group (0.41 ± 0.51 mmol/L/min) compared to the -30 group (1.89 ± 0.72 mmol/L/min, P = 0.029) and 0 group (2.11 ± 0.655 mmol/L/min, P = 0.030). The maximum blood glucose excursion was also lower in the -15 group (4.77 ± 0.52 mmol/L) compared to the -30 (6.48 ± 0.76 mmol/L, P = 0.025) and 0 group (6.93 ± 0.76 mmol/L, P = 0.022). The peak blood glucose level was significantly lower in the -15 group (9.26 ± 0.72 mmol/L) compared to the -30 group (11.74 ± 0.80 mmol/L, P = 0.007) and the 0 group (12.29 ± 0.93, P=0.009). Time spent in the 3.5 to 10 mmol/L range was highest in the -15 group (224.5 ± 25.0 min) and this difference was significant in comparison with the 0 group (90.5 ± 23.2 min, P=0.001) but not when compared to the -30 group (182.5 ± 28.2 min, P=0.212). There was no significant difference between the occurrences of glucose levels <3.5mmol/L between groups (P=0.901).
Conclusion: Administration of rapid acting insulin analogues at 15 minutes before mealtime results in lower postprandial glucose excursions and more time spent in the 3.5-10.0 mmol/L glucose range, without increased risk of hypoglycaemia.

Clinical outcomes after basal insulin initiation correlate with baseline oral antidiabetic drug therapy: a pooled analysis of clinical trial data

J. Leahy[1], J. Gill[2], R. Zhou[3], V.A. Fonseca[4];
[1]University of Vermont College of Medicine, Burlington, [2]sanofi-aventis US, Bridgewater, [3]Medpace, Cincinnati, [4]Tulane University Medical Center, New Orleans, USA.

Background and aims: This analysis evaluated the association between baseline oral antidiabetic drug (OAD) therapy and clinical outcomes after insulin initiation.
Materials and methods: The analysis included data from 11 prospective randomized controlled trials of insulin glargine (without prandial insulin) with/without OADs in adults with type 2 diabetes; 2171 patients received insulin glargine. These studies used strict, predefined insulin titration algorithms to achieve fasting glucose concentrations ≤5.55 mmol/L. Study duration varied from 24 to 48 weeks; outcomes for the pooled analysis were assessed at week 24. Statistical analysis compared patients taking 0 or 1 OAD at baseline (low use; 1.8% and 45.2% of patients, respectively) with those taking 2 OADs (52.2%), and patients on metformin (MET) only (8.5%) with those on sulfonylurea (SU) only (36.5%) or MET + SU (49.9%).
Results: Mean age was 58.6 years, 55.6% were male, and 88.3% were white. At week 24, patients with low baseline OAD use and those taking only MET had significantly greater A1C reductions (Table). Weight gain from baseline to week 24 was not significantly different based on the number or type of baseline OADs. However, patients with low baseline OAD use had significantly lower rates of symptomatic hypoglycemia vs those taking 2 OADs (P=0.0009), and those taking only MET had lower rates than those taking SU or MET + SU (P<0.0001) despite higher insulin doses (53 vs 37.5 vs 38.8 U).
Conclusion: Patients adding insulin to 0 or 1 baseline OAD, who may be in earlier stages of diabetes, showed a greater reduction in A1C with lower risk of hypoglycemia than those taking 2 OADs. The more favorable results of adding insulin to baseline MET vs SU or combined therapy support the Tier 1 recommendations of the current algorithm of the American Diabetes Association/European Association for the Study of Diabetes.

Table: A1C and Baseline (BL) OAD Use

BL OAD	BL A1C, %[a]	Week 24 A1C, %[a]	Δ in A1C From BL to Week 24, %[b]	Week 24 A1C ≤7.0%, n (%)

The DURABLE Trial: comparing durability of lispro mix 25 vs glargine

B.H.R. Wolffenbuttel[1], J.B. Buse[2], W.H. Herman[3], S.E. Hippler[4], S.A. Martin[5], H.H. Jiang[5], J.L. Scism-Bacon[5], J.L. Fahrbach[5];
[1]Endocrinology, University Medical Center Groningen, Netherlands, [2]UNC School of Medicine, Chapel Hill, [3]Internal Medicine and Epidemiology, U of Michigan, Ann Arbor, [4]OSFMG Clinical Research Center, OSFMG Center for Health Internal Medicine, Peoria, [5]Eli Lilly and Company, Indianapolis, USA.

Background and aims: To evaluate if adding twice-daily (bid) insulin lispro mix 25 (LM25: 25% lispro/75% insulin lispro protamine suspension) to oral antihyperglycaemic medications (OAMs) results in longer durability of glycaemic control than adding once daily (qd) insulin glargine (G). Durability was defined as duration of time patients (pts) maintained hemoglobin A1c (HbA_{1c}) goal (HbA_{1c} ≤7.0% or HbA_{1c} >7.0% but an increase of <0.4% from the last HbA_{1c} ≤7.0%).
Materials and methods: A total of 2091 pts with type 2 diabetes (T2D) aged 30-80 yrs, HbA_{1c} >7.0% on at least 2 OAMs were randomised to either LM25 bid or G qd. OAMs were continued. Insulin was titrated to fasting plasma glucose (FPG) and pre-evening meal plasma glucose <6.1 mmol/L for LM25, and FPG ≤5.5 mmol/L for G. All pts had up to 6 months (initiation phase) to achieve HbA_{1c} ≤7.0%, after which, pts with HbA_{1c} ≤7.0% advanced into the maintenance phase for up to an additional 2 years (total = 30 month study). Pts were discontinued from maintenance phase if HbA_{1c} was >7.5%. The primary objective was duration of time at HbA_{1c} goal, from when pts first attained HbA_{1c} goal.
Results: Of the 900 pts on LM25 and 918 pts on G who completed the initiation phase, 473 and 419, respectively, had an HbA_{1c} ≤7.0% at 6 months and continued into the maintenance phase. Baseline characteristics were similar across therapies except for age (LM25: 59±9 yrs; G: 57±9 yrs). The median time at HbA_{1c} goal was 16.8 months (95% CI, 14.0-19.7) for LM25 and 14.4 months (95% CI, 13.4-16.8) for G (p=0.040, log-rank test). At endpoint, HbA_{1c} goal was maintained for 202 (43%) pts on LM25 and 147 (35%) pts on G (p=0.006). Compared to pts unable to maintain HbA_{1c} goal, pts on LM25 who maintained HbA_{1c} goal throughout the study had lower baseline HbA_{1c} (p=0.043). Pts on G who maintained goal had: shorter duration of diabetes; lower baseline HbA_{1c}, mean post-meal plasma glucose (PG), and mean PG; and higher 1,5-anhydroglucitol (p<0.05 for all). There was no difference in the rate (episodes/patient/year) of overall (LM25 19; G 18), nocturnal (LM25 6; G 9), or severe (LM25 0.02; G 0.02) hypoglycaemia. Incidence of serious adverse events was not different.
Conclusion: LM25 therapy resulted in statistically longer durability than treatment with G, though the clinical relevance of this difference is unclear. Patients with a lower baseline HbA_{1c} were more likely to maintain HbA_{1c} goal, which supports the concept of early introduction of insulin therapy in T2D. In both groups, the median time to starter insulin failure illustrates the progressive nature of T2D, necessitating continued diligence and advancement of therapy.

Switching from premixed insulin to basal–bolus insulin glargine plus rapid-acting insulin: results of the ATLANTIC study

G. Storms[1], I. Colin[2], T. Veneman[3], C. Mathieu[4];
[1]St. Antonius Hospital, Utrecht, Netherlands, [2]CHR Clinique Saint-Joseph, Mons, Belgium, [3]Twenteborg Hospital, Almelo, Netherlands, [4]Katholieke Universiteit, Leuven, Belgium.

Background and aims: This study evaluated the efficacy and safety of switching from twice-daily premixed insulin to basal–bolus glargine (GLAR) plus rapid-acting insulin in a 'real-world' clinical practice setting in Belgium and The Netherlands.
Materials and methods: This was a prospective, 6-month, multicentre, non-interventional, observational study. Adults with Type 2 diabetes mellitus (T2DM) could be enrolled if they were being switched from twice-daily premixed insulin to basal–bolus GLAR plus insulin glulisine (GLU; The Netherlands) or any rapid-acting insulin (Belgium) due to poor glycaemic control. The primary objective was the proportion of patients with HbA_{1c} <7% at Month 6. Secondary objectives included changes in mean HbA_{1c}, fasting plasma glucose (FPG), self-monitored blood glucose (SMBG), weight, insulin dose, fasting blood lipid profile (FBLP), safety (including the incidence of symptomatic nocturnal and severe hypoglycaemia) and treatment satisfaction (DTSQs and DTSQc).
Results: A total of 214 patients were included: mean ± standard deviation age 64.4 ± 9.8 years, diabetes duration 12.1 ± 7.8 years, weight 89.5 ± 17.2 kg. GLAR was initiated with GLU, regular human insulin or insulin aspart in 81.7, 8.9 and 8.5% of patients, respectively. At baseline, 3.3% had HbA_{1c} <7%, which increased significantly at Months 3 and 6 to 20.1 and 24.9%, respectively (Table). Significant reductions over 6 months were observed in mean HbA_{1c}, FPG and SMBG. The mean total premixed insulin dose prior to switching was 65.2 U/day and the starting doses of GLAR and rapid-acting insulin were 28.1 and 35.7 U/day, respectively. Mean GLAR and rapid-acting insulin doses were significantly higher at Month 6. Mean weight increased by 0.67 ± 4.8 kg at Month 6 (not significant). No statistically significant changes in FBLP were observed at Month 6, although there was a trend toward a reduction in triglycerides (−14 mg/dL; p=0.063). At Month 6, 33.9 and 27.8% of patients reported a reduction in the incidence of nocturnal and severe hypoglycaemia, respectively, compared to the initial visit (both p<0.0001). Increases in these events were reported by 1.8 and 2.5%, with the remaining patients reporting no change. Overall, 22 adverse events were reported by 19 patients, including nine episodes of hypoglycaemia, which were considered non-serious. Treatment satisfaction improved significantly at Month 6 (DTSQs +5.9 and DTSQc +10.4; both p<0.0001).
Conclusion: In a Belgian and Dutch clinical practice setting, patients with T2DM poorly controlled on premixed insulin experienced significant improvements in glycaemic control and treatment satisfaction, without a concomitant increase in hypoglycaemic events or weight, when switched to basal–bolus GLAR plus rapid-acting insulin.

Pharmacokinetics of novel formulations of insulin analogues that provide a more rapid onset of action in diabetic miniature swine

R. Pohl, Y. Zhang-Benoit, N. Kashyap, S.S. Steiner;
Biodel Inc., Danbury, USA.

Background and aims: Commercial prandial insulin analog formulations have a more rapid onset of action than traditional regular human insulin preparations. A faster absorption profile is desirable to improve the timing of insulin release and reduce hypoglycemic events between meals. In this pre-clinical study, Insulin lispro (ILV), insulin aspart (IAV) and insulin glulisine (IGV) were re-formulated with safe excipients to improve their rate of subcutaneous absorption. The aim of this study was to evaluate the pharmacokinetic (PK) timing of these new rapid acting insulin analog formulations.
Materials and methods: ILV, IAV and IGV were formulated in a similar manner to VIAject (containing EDTA and citrate) and were compared to their commercial preparations (insulin lispro (IL), insulin aspart (IA), and insulin glulisine (IG)) in diabetic miniature swine (DMS). DMS were given a dose of 0.25 U/kg in lieu of their daily porcine insulin injection. Immediately following dosing, the swine were fed 500 g of their normal swine diet. Blood glucose and plasma insulin were sampled at -30, -20, -10, 0, 5, 10, 15, 20, 30, 45, 60, 75, 90, 120, 150, 240, 300, 360, 420, and 480 min. post dose. Insulin analog plasma levels were measured by ELISA technique.
Results: Results of timing related PK parameters Tmax and 1/2Tmax are shown in table below. In all cases, the new formulations ILV, IAV and IGV had significantly faster insulin absorption than their commercial counterparts, IL, IA and IG. Pharmacodynamics were consistent with the PK.
Conclusion: Viaject, a formulation of RHI combined with these exipients has completed phase III trials as an improved prandial insulin and is currently being reviewed by the FDA. The phase III clinical trials showed that not only was insulin absorption more rapid than RHI and analog insulins, but there was also a significant beneficial decrease in weight gain and reduction in hypoglycemia compared to RHI. This information, coupled with results of the present study, suggest existing rapid acting analogs could be reformulated with these safe excipients and result in a safe and efficacious improvement of these prandial insulins.

Comparative pharmacokinetics and pharmacodynamics of high-dose human regular U-500 insulin versus human regular U-100 insulin in healthy obese subjects

H. Linnebjerg[1], A. de la Pena[2], L. Morrow[3], H.H. Jiang[2], K. Win[3], L.L. Wolka[2], M. Hompesch[3], M. Riddle[4], J.A. Jackson[5];
[1]Lilly Research Laboratories, Eli Lilly and Company, UK, Surrey, United Kingdom, [2]Eli Lilly and Company, Indianapolis, USA, [3]Profil Institute for Clinical Research, Inc., Chula Vista, USA, [4]Oregon Health and Science University, Portland, USA, [5]Lilly USA, LLC, Indianapolis, USA.

Background and aims: Human regular U-500 (U-500R) insulin is used in the US and UK in high-dose insulin-treated diabetes patients with the advantages of smaller injection volumes and fewer injections as compared to U-100 insulins/analogues. However, only a few pharmacokinetic (PK) and pharmacodynamic (PD) studies of U-500R have been conducted since its introduction in 1997. The primary aim of this study was to evaluate the relative exposure after 2 clinically relevant doses of U-500R vs U-100 human regular insulin (U-100R) in healthy obese subjects. Other comparative PK/PD responses were evaluated.
Materials and methods: Twenty-four healthy obese subjects (male/female 14/10; age [mean±SD] 39.6±12.1 years; body weight 98.1±12.9 kg; BMI 34.4±2.6 kg/m^2) participated in a single-centre, 4-period, 4-sequence, cross-over, randomised, double-blinded, euglycaemic clamp study. Following administration of 50-IU and 100-IU doses of each formulation, subjects underwent euglycaemic clamps up to 24 hours. Serum immunoreactive insulin

was measured for PK evaluation. Glucose infusion rates were recorded for PD analysis.

Results: Results for the 100-IU dose are shown in the table. While overall exposure (AUC from time zero to return to baseline, $AUC_{0-t'}$) was similar between formulations at both 50-IU and 100-IU doses, the U-500R peak concentration (C_{max}) was significantly lower than that for U-100R at both doses . The time-to-peak concentration (t_{max}) was significantly longer for U-500R at the 100-IU dose only. Overall effect (G_{tot}) for U-500R was similar to U-100R at both doses. Peak effect (R_{max}) was lower for U-500R vs U-100R at both doses. Time-to-peak effect (tR_{max}) was shown to be prolonged for U-500R vs U-100R at the 100-IU dose only. Time variables reflective of duration of action (early and late tR_{max50}, tR_{last}) were prolonged for U-500R vs U-100R at both doses.

Conclusion: While $AUC_{0-t'}$ was similar at both 50-IU and 100-IU, the peak concentration was significantly lower for U-500 at both doses. The PD results are generally consistent with the PK. Both U-500R and U-100R exhibited long time-to-peak effect and duration of effect, with U-500R being significantly longer for these parameters vs U-100R. For T2D patients requiring high-dose U-100R therapy, this may have important clinical implications for bolus/basal insulin calculations. The longer duration of effect of U500R compared to U100R suggests that multiple daily injections of U500R without use of a basal insulin may be a plausible treatment option for obese patients with type 2 diabetes; further study is required to determine the safety and efficacy of such an approach.

100-IU Dose		Human Regular U-500 Insulin	Human Regular U-100 Insulin	Ratio (†) or Difference (‡) of LS Means	90% CI

More rapid onset and shorter duration of insulin exposure and action for 3 rapid insulin analogues coinjected with human hyaluronidase

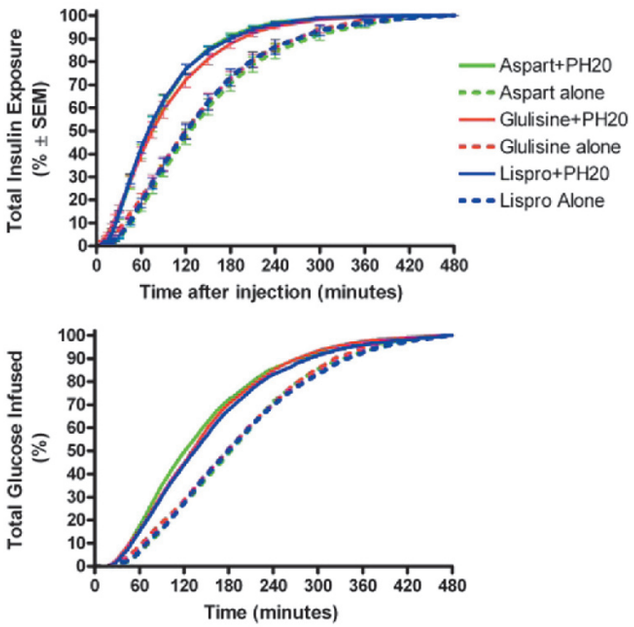
D. Muchmore[1], L. Morrow[2], M. Hompesch[2], E. Ludington[1], D. Vaughn[1];
[1]Halozyme Therapeutics, Inc., San Diego, [2]Profil Institute for Clincal Research, Chula Vista, USA.

Background and aims: This study compared the pharmacokinetic (PK) and glucodynamic (GD) responses to 3 rapid-acting insulin analogs (glulisine, lispro and aspart) ± coinjected recombinant human hyaluronidase (PH20)

Materials and methods: A 6-way crossover glucose clamp study was conducted in 14 healthy volunteers [8 male, 6 female; mean age 34 (23-53); mean BMI 24.7 kg/m2 (21.1-27.0)]. Euglycemic clamps (8h at 90% FBG w/o basal insulin infusion) were performed following 0.15 U/kg doses of each study drug SC in a random order. Specificity and sensitivity of the insulin immunoassay used for PK analysis was slightly different for the three analogs; data are graphed as cumulative values to allow direct comparison of timing differences for exposure and action across the 3 analogs.

Results: The three analogs w/o PH20 had generally comparable insulin time-exposure and time-action profiles [time to 50% of total insulin exposure (AUC) were 124, 123 & 131 min; time to 50% insulin action (Gtot) were 183, 186 & 187 min, for glulisine, lispro and aspart; all P>0.2] although glulisine had modestly more rapid onset (time to 10%) of exposure (40 v. 47 & 48 min; P=.005 & .0004) and action (67 v. 76 & 76 min; P=.025 & .021). PH20 accelerated the absorption of all three rapid-acting analogs, resulting in more physiologic fast-in, fast-out profiles: insulin exposure in the 1st hr increased to 191%, 229%, and 246% control and after 2 hrs decreased by 43%, 54%, and 57%; glucose infused in the 1st 2 hrs increased to 157%, 161%, and 182% control, and after 4 hours decreased by 48%, 44%, and 50% for glulisine, lispro and aspart, respectively (all P<.0001). With PH20, all 3 analogs had comparable profiles (times to 50% of total insulin exposure were 79, 71 & 73 min and time to 50% insulin action were 135, 140 & 127 min, for glulisine, lispro and aspart respectively; all P≥.1 between analogs w/ PH20) and each was notably faster than any marketed products alone (all P<.0001). All injections were well tolerated; all adverse events (mild or moderate) were procedure related. Also shown in the figure are cumulative insulin exposure and action for regular human insulin (RHI) from data collected in a separate but similar study.

Conclusion: Coinjection with PH20 was well tolerated and accelerated the absorption of all 3 insulin analogs to a comparable degree, resulting in more rapid onset and shorter duration of both insulin exposure and action.



966

Dissolving microneedles for percutaneous delivery of insulin

K. Takada, Y. Itoh;
Pharmacokinetics, Kyoto Pharmaceutical University, Japan.

Insulin (Ins) chip having 300 2-layered dissolving microneedle (DM) arrays on 254mm^2 were prepared by microfabrication technology where water-soluble thread-forming polymer, chondroitin sulfate (Chon) was used as the base. The obtained Ins DM chips were evaluated as a new TDDS. The mean lengths of the DM were 473.3±3.7(SE)μm, though the mean length of Ins loaded space was 328.1±3.5μm from the top of DMs. The diameters of the basement were 301.6±1.6μm. One chip contained 5.7±0.04 and 7.1±0.7 IU Ins by HPLC analysis. After administration of Ins chip to the abdominal skin of dogs, plasma glucose levels were measured. Maximum hypoglycemic effect appeared at 1.0±0.0 h. The minimum glucose levels were 46.5±3.9 and 36.1±5.8% as compared to the pre-dose level. By comparing the AAC (area above the plasma glucose level *vs*. time curve) obtained after sc injection of Ins solution, 4.0 IU, relative pharmacological availabilities (RPA) were 54.9±5.9 and 56.3±5.1%. Plasma Ins levels were also measured by ELISA. C_{max}s were 148.2±57.2 and 163.8±44.2 mIU/mL and T_{max}s were 0.75±0.0 and 0.75±0.0h. Relative bioavailabilities (RBA) against sc Ins injection were 72.0±34.4 and 79.7±26.5 %. Fluorescence microscopy experiment using a DM chip containing FITC-insulin (F-ins) showed that DM was dissolved in the inserted epidermal site of the skin within 5 min and thereafter F-ins diffused both horizontal and vertical directions of the skin within 30 min. Histological study on the administered skin showed that there was no damage on the skin. As chip is made of Ins and Chon, safety is established. Ins DM chip is a useful TDDS and we want to proceed to clinical phase I study.

No generation of insulin antibodies in subjects with impaired glucose tolerance treated with buccal spray insulin

A. Palermo, N. Napoli, D. Tuccinardi, S. Manfrini, M. Altomare, S. Leotta, P. Pozzilli;
Campus Bio-Medico di Roma, Italy.

Background and aims: In patients with impaired glucose tolerance (IGT), upon implementation of life style changes and metformin, a third returns to normal glucose tolerance, a third continues with IGT and the rest goes on to develop clinical type 2 diabetes. An increased risk for cardiovascular disease occurs in the latter two groups even though there is no progression to diabetes. The implementation of treatment strategies to lower postprandial hyperglycaemia has been recommended by the IDF guidelines. A previous proof of concept study demonstrated that treatment with buccal spray insulin (Oral-lyn™) can be a valuable tool for managing subjects with IGT. Thus, treatment with 12 puffs was followed by a significant 29.6% decrease in mean plasma glucose at two-hours and a 26.8% decrease at three-hours Considering all time points OGTT, there was a mean reduction of 15.8% in mean plasma glucose following buccal spray insulin. No hypoglycaemia episodes were recorded. The aim of this study was to evaluate the effect of Oral-lyn™ on metabolic and immunological parameters in subjects affected by IGT who were exposed to long term treatment with this insulin formulation.
Material and Methods: We have designed a randomized controlled trial in 36 subjects with IGT comparing buccal spray insulin (12 puffs per meal) plus physical exercise and diet vs. physical exercise and diet only (control group). Primary endpoint is the reduction of HbA1c of 0.3 % at 6 month treatment between the experimental vs control group. Secondary endpoints include the evaluation of production of antibodies against insulin (IA), glucose variability (measured with continuous glucose monitoring), changes in body weight, number of hypoglycemic events after buccal spray insulin treatment. Insuiln antibodies were measured using a DASP recognized assay.
Results: Subjects enrolled in the treatment group did not suffer of hypoglycaemia episodes. IA were negative at entry into the study in IGT subjects and treatment with buccal spray insulin did not induce generation of IA .
Conclusion: Our preliminary data show that subjects treated with buccal spray insulin do not develop autoimmunity vs insulin as usually occurs with subcutaneous or other forms of insulin delivery (pulmonary). This may represent an additional benefit of buccal insulin, considering also the more acceptable route of administration.

Clinical performance of the insulin infusion set InsuPatch that applies local heat to the infusion site

G. Freckmann[1], A. Westhoff[1], S. Pleus[1], N. Jendrike[1], E. Zschornack[1], C. Haug[1], L. Krinelke[2];
[1]Institute for Diabetes-Technology GmbH at the University of Ulm, Germany, [2]Roche Diabetes Care AG, Burgdorf, Switzerland.

Background and aims: The importance of good glycemic control in therapy of people with type 1 diabetes is well known. Using rapid acting insulin analogues, early postprandial hyperglycemias and late postprandial hypoglycemias are still common. In this study, the effect of the local skin heating device InsuPatch on postprandial blood glucose levels after differently composed meals was investigated.
Materials and methods: Twenty-four type 1 diabetic subjects on CSII (10 male, 14 female, age: 43.5±11.3 years, diabetes duration 18.3±10.5 years, HbA1c 7.4±0.8%, daily insulin need 0.58±0.15 U/kg/d, BMI 25.0±3.0 kg/m2 [mean ± SD]) were included in this study. With data from an intensive monitoring phase of five days, the therapy parameters were optimized. During a clinical visit, subjects had standardized meals on four days, with the InsuPatch device heating on two days. Two pairs of breakfast meals (65% carbohydrates, 15% protein, 20% fat) and two pairs of dinner meals (40% carbohydrates, 20% protein, 40% fat) were obtained for evaluation. The impact of local skin heating on insulin absorption was measured using the normalized AUC 0-120 min above baseline blood glucose (BG).
Results: A total of 42 breakfast meal pairs and 38 dinner meal pairs were usable for the analysis. A significant difference between heated and not heated InsuPatch was found for the normalized AUC 0-120 min. The difference for dinner meals ($p<0.005$; AUC 0-120 for BG above baseline not heated 30.8±31.0 mg/dl, heated 18.4±23.9 mg/dl), representing slowly resorbed meals, was stronger than for breakfast meals, representing fast resorbed meals ($p<0.05$, AUC 0-120 for BG above baseline not heated 66.4±32.8 mg/dl, heated 56.8±34.0 mg/dl). The BG level above baseline 90 minutes after the meal was significantly lower with heated InsuPatch device especially after dinner meals ($p<0.001$, BG90 above baseline not heated 41.1±47.9 mg/dl, heated 25.1±37.2 mg/dl). The AUC 0-60 minutes for the venous insulin concentration after breakfast was significantly larger with heated InsuPatch ($p<0.001$, AUC 0-60 for insulin concentration above baseline not heated 42.8±23.4 mU/l, heated 53.1±28.8 mU/l). The number of hypoglycemic events showed no statistically significant difference.
Conclusion: This study shows that local heating of the skin around the infusion site was significantly increasing early insulin levels post delivery as well as significantly reducing post-prandial blood glucose increase without causing more hypoglycemia. The device provides faster insulin action, however it has to be further evaluated to which extent the device is effective in daily life use.

Biocompatibility of the ultra-rapid insulin VIAject® with continuous insulin infusion sets

F. Flacke[1], P.B. Musholt[2], A. Weise[2], C. Schipper[2], A. Krasner[1], T. Forst[2], S.S. Steiner[1], A. Pfützner[2];
[1]Biodel, Inc., Danbury, USA, [2]IKFE-Institute for Clinical Research & Development, Mainz, Germany.

Background and aims: Use of prandial insulins with a more rapid absorption profile would be expected to provide improved postprandial glucose control with lower risk of hypoglycemia during treatment with continuous subcutaneous insulin infusion. Viaject is a formulation of recombinant human insulin that has been shown to be more rapidly absorbed than insulin lispro or regular insulin. The goal of this investigation was to explore the biocompatibility of VIAject with CSII infusion systems from several insulin pump manufacturers.
Materials and methods: Infusion sets used for the following insulin pumps were included into this investigation: (ACCUCHEK® Combo (Roche Diagnostics), Paradigm® 722 (Minimed-Medtronic), Animas® IR2020 (Animas, Johnson&Johnson), and Omnipod® (Insulet®). Three catheters (steel needle and/or Teflon catheter) of each product were tested. The pumps were filled with VIAject and emptied over 96 h at 37°C though the infusion systems. Samples of the delivered insulin product composition were collected after 0, 1, 3 and 4 days. Determinations of insulin, its degradation products and high molecular weight proteins were performed by a USP-conform HPLC-method.
Results: All mean insulin concentrations and by-product concentrations were in the acceptable ranges by USP specifications (insulin: 95-105 %, A21 desamido insulin < 2 %, total contamination excl. A21 desamido insulin < 2 %, high molecular weight products < 1.7 %). The results were similar to those of a reference sample of insulin VIAject stored in a glass vial under the same environmental conditions.
Conclusion: This investigation confirmed that VIAject is pharmacologically stable when delivered though clinically used infusion systems under the conditions of CSII therapy. The pharmacological properties of VIAject appear suitable for pump use which can now be investigated in clinical trials.

A pocket instrument for calculating insulin need in the management of type 1 diabetes

A. Maurizi, A. Palermo, G. Beretta Anguissola, D. Benevento, A. Lauria, E. Cipponeri, D. Tuccinardi, S. Manfrini, P. Pozzilli;
Campus Bio-Medico di Roma, Italy.

Background: Intensive insulin therapy is today the gold standard form of therapy in patients with type 1 diabetes. For achieving optimal metabolic control, adjustments of the insulin dose at meal times must be made before each injection by taking into account several parameters including blood glucose levels, the insulin/carbohydrate ratio, the carbohydrate intake at each meal and the intensity of physical exercise post injection. A new tool recently developed for the establishment of the insulin dose to be administer (Calsulin) takes into account all above parameters in a matter of seconds and

displays the insulin units to be injected. Aim of this randomised trial was to evaluate the efficacy of Calsulin on metabolic control as assessed by HbA1c in patients with type 1 diabetes undergoing intensive insulin therapy.
Material and methods: A total of 40 consecutive patients affected by type 1 diabetes aged 18-65 years with disease duration > 1 year, were included in the study. HbA1c was evaluated at entry into the trial and at 3 and 6 months follow-up. Patients were randomised to Calsulin or standard education for insulin treatment (control group). Paired t test (two tailed) and analysis of variance were used to evaluate differences in HbA1c at different time points.
Results: HbA1c at entry was 7.9% ± 1.0 (SD) in Calsulin treated group and 7,8% ± 1.6 (SD) in control patients (p:NS). Already after 3 months follow-up there was a tendency for an improvement in HbA1c levels in the Calsulin treated group vs. control group (7.3% ± 0.5 vs. 7.7% ± 1.0, respectively, p:NS). Taking into account the 6 months period of observation, a statistically significant reduction in HbA1c levels was observed in the Calsulin treated group vs. control group (-0.85% vs. -0.07% difference, respectively, p<0.05).
Conclusions: The results of this study showed that this simple pocket instrument of the size of a small calculator is an acceptable and practical tool to make the process of calculating the number of insulin units very simple and, most importantly, helps to improve metabolic control as shown by a significant reduction of HbA1c levels compared to standard methods used for calculating the required insulin doses.

PS 90 Long-acting insulin analogues

971

Insulin degludec: less pharmacodynamic variability than insulin glargine under steady state conditions

T. Heise[1], L. Hermanski[1], L. Nosek[1], A. Feldmann[1], S. Rasmussen[2], T.K. Stryhn[2], H. Haahr[2];
[1]Profil Institut für Stoffwechselforschung, Neuss, Germany, [2]Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Insulin degludec (IDeg) is a new generation basal insulin analogue with an ultra-long (>24-hour half-life) duration of action. We compared the pharmacodynamic (PD) variability of IDeg and insulin glargine (IGlar) under steady-state conditions.
Materials and methods: In this randomised, double-blind, parallel-group study, 54 subjects with type 1 diabetes (48 male, 6 female, age 38±10 years (mean±SD), HbA1c 7.7±0.9%, BMI 24.6±2.2 kg/m²) received 0.4 U/kg of either IDeg or IGlar once daily for 12 days. On treatment days 6, 9 and 12 PD-profiles were investigated over 24h with the euglycaemic glucose clamp technique (Biostator, pre-dose blood glucose (BG) stabilisation at the clamp level of 5.5 mmol/l with iv insulin that was stopped post-dose when BG decreased by 0.3 mmol/l and when glucose infusion was initiated). Within-subject variability (expressed as coefficient of variation - CV) was estimated using a linear mixed model on log-transformed PD endpoints. All PD endpoints were derived from the glucose infusion rate (GIR) profiles during the clamps.
Results: IDeg produced significantly less overall PD variability than IGlar between days 6, 9 and 12 on all protocol-specified PD variability parameters including total metabolic effect (AUC-$GIR_{0\text{-}24h}$, CV 20 vs. 82%, p<0.0001), the effect in the last 22 hours (AUC-$GIR_{2\text{-}24h}$ (not influenced by iv insulin during the clamp), CV 22 vs. 92%, p<0.0001) and the maximum effect (GIR_{max}, CV 18 vs. 60%, p<0.0001). Total metabolic effect (AUC-$GIR_{0\text{-}24h}$) tended to be higher with IDeg than with IGlar (geometric mean 2618 vs 1953 mg/kg, ratio 134%). The individual within-subject variability was consistently lower for IDeg compared with IGlar when the individual CVs were compared in a ranked order (figure). IDeg's metabolic effect was exactly evenly distributed between the first and the second twelve hours (ratio of AUC-$GIR_{0\text{-}12h}$/AUC-$GIR_{0\text{-}24h}$ geometric mean: 0.50 vs. 0.57 with IGlar) and this distribution was also less variable than with IGlar (CV 10 vs 17%, p<0.001). Both insulin formulations were well tolerated. No serious adverse events occurred. In total, 166 (20 nocturnal) hypoglycaemic episodes, defined as BG < 2.8 mmol/l with or without hypoglycaemic symptoms, were observed with IDeg compared with 182 (37 nocturnal) episodes with IGlar. There were no severe hypoglycaemic episodes in this study. No injection site reactions occurred with either insulin.
Conclusion: Under steady-state conditions after once daily administration, the effect of the novel basal insulin analogue insulin degludec is evenly distributed over each 24 h period and significantly less variable than that of insulin glargine. The results suggest a less variable and more stable glucose-lowering insulin effect for IDeg compared with IGlar.

Insulin degludec: multi-hexamer formation is the underlying basis for this new generation ultra-long acting basal insulin

I. Jonassen[1], S. Havelund[1], U. Ribel[1], T. Hoeg-Jensen[1], D.B. Steensgaard[1], T. Johansen[2], H. Haahr[2], E. Nishimura[1], P. Kurtzhals[1];
[1]Diabetes Research Unit, Novo Nordisk A/S, Maaleov, [2]Global Development, Novo Nordisk A/S, Soeborg, Denmark.

Background and aims: Insulin degludec is a new generation ultra-long acting basal insulin analogue in clinical development. The insulin degludec molecule retains the human insulin amino acid sequence except for the deletion of ThrB30 and the addition of a 16-carbon fatty diacid attached to LysB29 via a glutamic acid spacer. It is well established that absorption rate from subcutaneous tissue is determined by molecular size. Therefore the aim of this study was to demonstrate that under *in vitro* conditions mimicking the physiological injection site, insulin degludec self-associates to form large multi-hexamer assemblies and that this ultimately results in an ultra-long and peak-less pharmacokinetic profile when administered to people with type 1 diabetes.
Materials and methods: Size exclusion chromatography (SEC) experiments were performed to characterise the molecular size of self-assembled units of insulin degludec, in particular, hexamers, di-hexamers and multi-hexamers. Various pharmaceutical formulations containing zinc ions, phenol and m-cresol were examined by SEC analysis to simulate conditions before and after sub-cutaneous injection. To examine the pharmacokinetic (PK) profile of insulin degludec, a clinical pharmacology study was conducted in subjects (n=12) with type 1 diabetes. The steady state PK profile (24 hour) was determined after 6 consecutive days of once daily dosing with insulin degludec (5.0 nmol/kg).
Results: SEC analysis demonstrated that insulin degludec forms di-hexamers in the presence of phenol and m-cresol. To mimic a subcutaneous injection, further SEC analysis was conducted in the absence of phenol and m-cresol and it was revealed that there occurs a reorganisation from di-hexamers to multi-hexamer assemblies which remain in solution at physiological pH. In the clinical pharmacology study where insulin degludec was administered to subjects with type 1 diabetes, the steady-state PK profile demonstrated a smooth and stable exposure over 24 hours (see figure). Insulin degludec was found to have a t½ longer than 24 hours and was detectable in circulation for at least 96 hours after the final injection.
Conclusion: In summary, insulin degludec is a new generation soluble basal insulin with an ultra-long, peak-less pharmacokinetic profile attributed to multi-hexamer formation and slow release of insulin degludec monomers. Insulin degludec has the potential to address major challenges in diabetes care such as hypoglycaemia as well as compliance by providing more flexible dosing schedules.

Insulin deglucec, a new generation ultra-long acting insulin, in a mealtime + basal regimen in people with type 1 diabetes: comparison to insulin glargine

L. Meneghini[1], P. Home[2], J.H. DeVries[3], J. Jendle[4], L. Endahl[5], K. Lyby[5], T. Johansen[5], A. Roberts[6], R. Ratner[7], U. Wendisch[8], K.I. Birkeland[9];
[1]University of Miami School of Medicine, USA, [2]Newcastle University, United Kingdom, [3]University of Amsterdam, Netherlands, [4]Örebro University Hospital, Sweden, [5]Novo Nordisk A/S, Soeborg, Denmark, [6]Royal Adelaide Hospital, Australia, [7]MedStar Research Institute, Washington, USA, [8]Gemeinschaftspraxis für Innere Medizin und Diabetologie, Hamburg, Germany, [9]Oslo University Hospital, Norway.

Background and aims: Insulin degludec (IDeg) is a novel insulin analogue that forms soluble multi-hexamer assemblies after subcutaneous injection (s.c.), resulting in ultra-long duration of action. This phase 2, 16-week, open-label, randomised, three-arm, parallel-group trial investigated the efficacy and safety of candidate formulations of IDeg in people with type 1 diabetes.
Materials and methods: Participants (mean age 45.8 years, HbA_{1c} 8.4 %, fasting plasma glucose (FPG) 9.9 mmol/l, BMI 26.9 kg/m^2) injected (s.c.) IDeg (n=59), an alternative formulation of IDeg (development discontinued, data not shown; n=60) or insulin glargine (IGlar; n=59) once daily in the evening, combined with meal-time insulin aspart. Basal insulin was titrated to achieve FPG 4.0-6.0 mmol/l.
Results: At 16 weeks, mean HbA_{1c} was comparable (IDeg 7.8%, IGlar 7.6%; estimated treatment difference = 0.1% (SE 0.1%)), as was FPG (IDeg 8.3 mmol/l, IGlar 8.9 mmol/l; estimated treatment difference = -0.6 mmol/l (SE 0.7 mmol/l)). At end-of-trial, mean total daily insulin dose was comparable to baseline (IDeg 60 U/day; IGlar 51 U/day), with minimal increases in mean basal insulin dose for both IDeg (from 29 to 30 U/day) and IGlar (from 23 to 26 U/day). The rate of confirmed hypoglycaemia (plasma glucose < 3.1 mmol/l or requiring assistance) was 28% lower for IDeg compared to IGlar (47.9 vs. 66.2 events/patient year; relative rate = 0.72 (95% CI: 0.52; 1.00)). The overall rate of confirmed nocturnal hypoglycaemia was 58% lower for IDeg compared with IGlar (5.1 vs. 12.3 events/patient year; relative rate = 0.42 (0.25; 0.69)). Very few severe hypoglycaemic events were reported for IDeg and IGlar (7 vs. 6 events). The overall rate of adverse events was similar between basal insulins, with no specific pattern or clustering. No injection site reactions were observed.
Conclusion: In this proof-of-concept trial, IDeg was safe and well-tolerated and provided comparable glycaemic control to IGlar at similar doses, with a reduced rate of confirmed hypoglycaemia.

974

Insulin degludec: a new ultra-long, basal insulin designed to maintain full metabolic effect while minimizing mitogenic potential

E. Nishimura, A.R. Sørensen, B.F. Hansen, C.E. Stidsen, G.S. Olsen, L. Schäffer, C. Bonnesen, A.C. Hegelund, A. Lundby, I. Jonassen;
Diabetes Research Unit, Novo Nordisk A/S, Maaleov, Denmark.

Background and aims: Insulin degludec (IDeg) is a new generation basal insulin analogue in clinical development, designed to allow the formation of soluble multi-hexamer assemblies upon subcutaneous injection to give an ultra-long peak-less pharmacokinetic profile. The aim of the present study was to investigate the metabolic responses and molecular safety (IGF-1 receptor affinity and in vitro mitogenicity) of IDeg.
Materials and methods: Insulin and IGF-1 receptor binding studies were conducted using recombinant human insulin receptors (both isoforms, hIR-A and hIR-B) and human IGF-1 receptors. Scintillation proximity assays using solubilised receptors from transfected BHK cells were conducted in the absence of albumin. Receptor kinetic studies were conducted using intact BHK cells expressing the hIR-A. The mitogenic effect of insulin degludec was determined by measuring ^{3}H-thymidine incorporation into L6 myoblasts expressing HIRs (L6-HIR), primary human mammary epithelial cells (HMEC) as well as COLO-205 and MCF-7cell lines (from human colon and mammary adenocarcinomas, respectively). The metabolic effects of IDeg were determined by: (1) lipogenesis in rat adipocytes (^{3}H-glucose into lipid), (2) glycogen accumulation in rat hepatocytes and (3) glycogen synthesis in rat skeletal muscle cells, L6-HIR and MCF-7 cells (^{14}C-glucose into glycogen).
Results: The affinity of IDeg for both human insulin receptor isoforms (HIR-A and - B) was found to be similar (13% and 15% relative to human insulin,

HI) while the affinity for the human IGF-1 receptor was lower (2% relative to HI). The kinetics of IDeg binding to the hIRA was not significantly different from that of HI. The mitogenic response measured in L6-HIR, HMEC, COLO-205 and MCF-7 cells, in the absence of alubmin, ranged from 4-14% relative to HI. IDeg elicited the same metabolic responses and same maximal effect as HI: lipogenesis in rat adipoctes, glycogen accumulation in rat hepatocytes and glycogen synthesis in rat muscle cells. Furthermore, in cellular assays where no albumin was added (hepatocytes and MCF-7 cells), the *in vitro* metabolic potency was determined to be in the range of 8-20% resulting in a mitogenic/metabolic potency ratio of ≤1.
Conclusion: In summary, insulin degludec is a full agonist at the insulin receptor and maintains the metabolic responses of HI. This is in agreement with phase 2 trial results, where IDeg gave comparable glycaemic control as insulin glargine at similar molar and unit doses in subjects with type 1 or 2 diabetes. The low IGF-1 receptor binding affinity and the low mitogenic/metabolic potency ratio indicate that the modifications made to IDeg do not compromise molecular safety.

Once-daily use of a new generation ultra-long acting basal insulin with a bolus boost in insulin-naïve people with type 2 diabetes: comparison with insulin glargine

R. Cuddihy[1], C.J. Tack[2], T. Heise[3], J. Davidson[4], D. Gouet[5], A. Liebl[6], E. Romero[7], H. Mersebach[8], P. Dykiel[8], R. Jorde[9];
[1]International Diabetes Center, Minneapolis, USA, [2]Radboud University Nijmegen Medical Centre, Netherlands, [3]Profil Institut für Stoffwechselforschung, Neuss, Germany, [4]Southwestern Medical School, Dallas, USA, [5]Hôpital Saint Louis, La Rochelle, France, [6]Center for Diabetes and Metabolism, Bad Heilbrunn, Germany, [7]Instituto de Endocrinologia, UVA, Valladolid, Spain, [8]Novo Nordisk A/S, Soeborg, Denmark, [9]University of Tromsø, Norway.

Background and aims: Insulin degludec (IDeg) is a novel insulin analogue that forms soluble multi-hexamer assemblies after subcutaneous injection, resulting in ultra-long duration of action. IDegAsp is a soluble insulin product comprising IDeg (70%) and insulin aspart (IAsp, 30%). The aim of this phase 2, 16-week, open-label, randomised, parallel-group, treat-to-target trial was to investigate the safety and efficacy of IDegAsp in insulin-naïve people with type 2 diabetes inadequately controlled on oral antidiabetic drugs.
Materials and methods: Subjects (mean: 59.1 yrs, HbA_{1c} 8.5%, fasting plasma glucose (FPG) 11.6 mmol/l, BMI 30.3 kg/m^2) received once-daily IDegAsp (n=59), an alternative formulation of IDegAsp (AF: 55% IDeg and 45% IAsp; n=59) or insulin glargine (IGlar; n=60), all in combination with metformin, for 16 weeks. Insulin was dosed (s.c.) before dinner and titrated to a FPG target of 4.0-6.0 mmol/l. At the end of the 16-week treatment period, patients underwent a 72-h continuous glucose measurement (CGM).
Results: After 16 weeks, mean HbA_{1c} decreased from baseline in all treatment groups (IDegAsp: -1.31%; AF: -1.46%; IGlar: -1.29%) to comparable end-of-trial values (IDegAsp: 7.0%; AF: 7.2%; IGlar: 7.1%; *p*=NS for all pairwise comparisons). A similar proportion of subjects achieved HbA_{1c}<7.0% without confirmed hypoglycaemia in the last 4 weeks of treatment (IDegAsp: 51%; AF: 47%; IGlar: 50%). Mean self-measured 2-h post-dinner PG increment was lower for IDegAsp (0.13 mmol/l) and AF (0.24 mmol/l) than IGlar (1.63 mmol/l). These findings were mirrored by mean 2-h post-dinner interstitial glucose (IG) increments determined by CGM. The mean total time spent in hyperglycaemia (IG>12 mmol/l) per day tended to be lower for IDegAsp (2.2 h) and AF (2.2 h) compared to IGlar (2.7 h). Mean FPG was similar across treatments (IDegAsp: 6.8 mmol/l; AF: 7.4 mmol/l; IGlar: 7.0 mmol/l). At end-of-trial, mean daily insulin doses were lower for IDegAsp (0.38 U/kg) and AF (0.36 U/kg) than IGlar (0.45 U/kg).
No severe hypoglycaemic events were reported. Rates of confirmed hypoglycaemia (PG<3.1 mmol/l) were lower for IDegAsp and IGlar than AF (1.2, 0.7 and 2.4 events/patient year). The proportion of subjects having at least one episode of near-hypoglycaemia (IG<3.5 mmol/l) over the course of a 72-h CGM was similar amongst groups (IDegAsp: 46%; AF: 44%; IGlar: 54%). Very few confirmed nocturnal hypoglycaemic events were reported for IDegAsp (1 subject; 1 event) and IGlar (3 subjects; 3 events) compared to AF (10 subjects; 27 events). Adverse events with a possible or probable relation to insulin were only reported for AF (5 subjects; 5 events).
Conclusion: This proof-of-concept trial showed once-daily IDegAsp to be safe, well tolerated and effective. IDegAsp provided comparable overall glycemic control to IGlar at similar rates of hypoglycaemia, with the additional benefit of post-dinner PG control.

Efficacy and goal attainment with insulin glargine vs comparators

M.A. Banerji[1], M. Baron[2], L. Blonde[3];
[1]SUNY Downstate Medical Center, Brooklyn, [2]sanofi-aventis US, Bridgewater, [3]Ochsner Medical Center, New Orleans, USA.

Background and aims: Clinicians have many type 2 diabetes (T2DM) treatment options. We evaluated patient level data from similar prospective, randomized, controlled studies to assess the likelihood of achieving glycemic control after 24 weeks of insulin glargine (GLAR) vs comparators (C) by baseline glycated hemoglobin A1C (A1C) category (<8.0%, 8.0% to <9.0%, 9.0% to <10.0%, and ≥10.0%).
Materials and methods: Data were pooled from 9 similar studies (N=2938) meeting the following criteria: included insulin-naive patients with T2DM, uncontrolled on oral antidiabetic drugs (OADs), randomized to addition of GLAR (n=1462) or C (OADs, NPH, lispro, or premix; n=1476) and utilized similar insulin titration algorithms.
Results: Groups were comparable at baseline (56% male, 83.5% white, mean age 57 y, diabetes duration 8.6 y, A1C 8.7%, body mass index 31.6 kg/m^2). A1C reductions at week 24 were greater with GLAR vs all C (-1.68 and -1.51%, *P*<0.001); and when evaluated vs specific comparators, reductions were greater with GLAR vs OADs and vs. premixed insulin, but similar to NPH and lispro. Proportions of patients achieving ≥1.0% reduction in A1C and achieving A1C ≤7.0% were greater with GLAR vs all C, and vs OADs (Table). The comparisons vs specific insulins failed to reach significance. When stratified by baseline A1C category, A1C improvements were similar between GLAR and OADs if A1C <8.0% but greater with GLAR if A1C ≥8.0%; similar between GLAR and other insulin C for all categories except a greater reduction if <8.0% vs premixed insulin. Hypoglycemia event rates were significantly lower for GLAR vs NPH, lispro, and premixed insulin, and higher for GLAR vs OADs (Table). Severe hypoglycemia was lower for GLAR than premixed insulin (0.02 vs 0.08 events\patient\year, *P*< 0.05), and not different between GLAR and OADs, NPH, or lispro. Changes in weight were similar between GLAR and any C. Incidence of edema was higher with OADs than GLAR, largely as the result of 2 trials in which the OAD comparator was a thiazolidinedione.
Conclusion: Initiating GLAR in patients uncontrolled on OADs was associated with better efficacy and goal attainment overall, vs C across the A1C continuum, and compared with OADs when baseline A1C was ≥8.0%. Efficacy across A1C categories was similar for insulin comparators; however, hypoglycemia rates were lower with GLAR.

Table. A1C and Hypoglycemia

Treatment	Week 24 A1C ≤7.0% (%)	Hypoglycemia Event Rate (Any), Events/Patient/Year

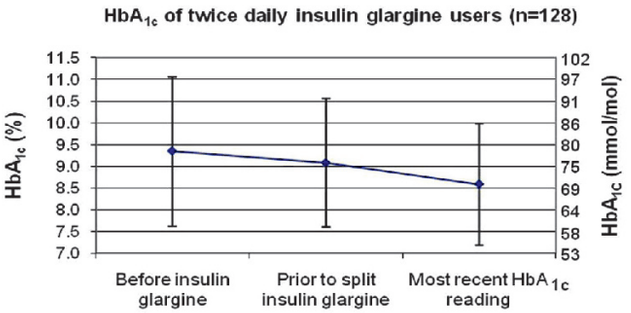
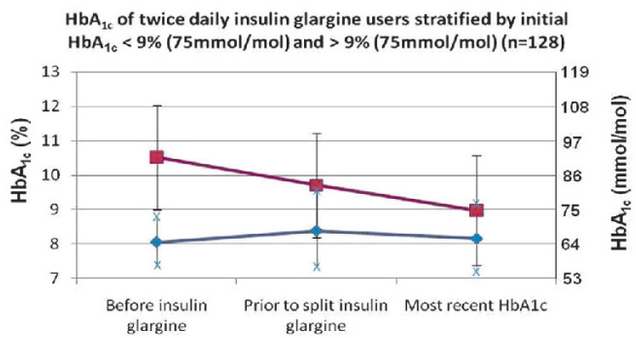
Improved glycaemic controls for patients on twice daily dosing regime of insulin glargine compared to those on a once daily dosing regime

K. Dhatariya[1], J. Yeong[2];
[1]Elsie Bertram Diabetes Centre, Norfolk and Norwich University Hospital NHS Trust, [2]School of Medicine, Health Policy and Practice, Norwich, United Kingdom.

Background and aims: Insulin glargine is a long acting once-daily insulin formulation, which is used to achieve glycemic control in patients with type 1 or type 2 diabetes mellitus. It is unclear whether better glycaemic control, in terms of HbA_{1C}, is achieved with twice daily dosing of insulin glargine compared to once daily adminstration.
Materials and methods: We conducted a retrospective case note analysis to evaluate whether there is any change in HbA_{1C} values among type 1 or type 2 diabetic patients after switching from a once-daily to twice daily insulin glargine regime. Data was collected as a part of a local service evaulation on diabetes care using patient notes and database laboratory results.
Results: A total of 206 patients were included with 38% on once daily insulin glargine (n=78) and 62% on twice daily insulin glargine (n=128). Of the 128 patients using a twice daily insulin glargine dosing regime, we found that switching from previous insulin therapy to once daily insulin glargine was associated with a average decrease in HbA_{1C} of 0.27% (3 mmol.mol) and there was a further decrease of 0.49% (5.4 mmol/mol) when the insulin glargine was changed to a twice daily dosing regime. This decrease was further evident when starting HbA_{1C} was greater than 9%.
Conclusion: Our data suggests that patients on a one daily dosing regime of insulin glargine may benefit from reduction in HbA_{1C} levels by switching to a twice-daily insulin glargine regime.





978

MAGE revisited: Evaluation of glucose variability with once daily glargine vs NPH insulin in type 2 diabetes

G. Silvani, S. Acquati, R. Manini, C. Ragazzini, S. Taroni, F. Donadio, L. Buci, L. Gagliardi, A. Tartaglia, M. Nizzoli;
Endocrinology, G.B. Morgagni - L. Pierantoni Hospital, Forlì, Italy.

Background and aims: Insulin combination regimens, i.e. a single bedtime injection of long-acting insulin added to oral anti-hyperglycaemic agents, are widely used in the secondary failure treatment of type 2 diabetes (t2DM); however most basal insulin formulations do not provide a constant and reliable 24-h insulin supply and are associated with an high risk of nocturnal or early morning hypoglycaemia. Aim of this perspective study was to evaluate the efficacy and safety of once daily glargine vs NPH insulin on glucose control and variability, expressed by Service's MAGE (Mean Amplitude of Glycaemic Excursions), in combination therapy of t2DM.
Materials and methods: In 40 t2DM patients, aged 62.5±8.3, overweight (BMI 29.1±6.0 kg/sq.m)and in a poor glycaemic control (HbA1c 9.1±1.2%)on a combination treatment with once daily bedtime NPH insulin 0.21±0.07 IU/kg/day and oral agents, sulphonylureas and metformin, after a 2-weeks run-in-period NPH was replaced by the same dose of glargine at the same time while oral agents were unchanged. Body weight, HbA1c and fasting C-peptide were evaluated at baseline and after 6 weeks during which, as well as in 2-weeks run-in-period, the patients provided a weekly self-monitored 6-points blood glucose profile (before and 2 h after breakfast, lunch and dinner) and recorded daily any hypoglycarmic episode. The mean glucose values of self-monitored profiles in run-in-period were compared point by point with the glargine treatment last 2 weeks profiles and MAGE was calculated.
Results: After glargine 6-weeks treatment body weight (as BMI) and C-peptide levels were unchanged; a slight but not significant decrease was observed in HbA1c (8.8±1.4 p=0.052); only fasting blood glucose (p=0.042)and 2-h post-breakfast glucose (p=0.028)significantly decreased while MAGE reached a more significant difference (71.4±15.6 vs 92.3±16.5 mg/dl p<0.001); moreover on glargine treatment the percentage of symptomatic hypoglycaemias was significantly lower (- 39.5% p=0.012).
Conclusion: Glargine insulin instead of NPH did not improve the short-term glycaemic control in combination therapy of t2DM patients:only two mean glucose levels significantly decreased in the six-points self-monitored profile while decrease of HbA1c was not significant. On the contrary glargine treatment was effective to reduce glucose variability, according to highly significant decrease of MAGE, and to lower the frequency and seriousness of hypoglycaemic episodes. In a blind post-study interview with DTSQ 29 patients (72.5%) declared an improvement of well-being, likely due to the lesser extent of glycaemic excursions.

979

Efficacy and safety of insulin lispro protamine suspension versus insulin glargine added to oral antihyperglycaemic medications and exenatide in patients with type 2 diabetes

R.F. Arakaki[1], T.C. Blevins[2], D.R. Liljenquist[3], J.K. Wise[4], H.H. Jiang[5], K.K. Schneider[5], J.G. Jacobson[5], S.A. Martin[5], J.A. Jackson[5];
[1]University of Hawaii, Honolulu, [2]Texas Diabetes and Endocrinology, Austin, [3]Rocky Mountain Diabetes and Osteoporosis Center, Idaho Falls, [4]Diabetes and Metabolism Assoc, Metairie, [5]Eli Lilly and Co, Indianapolis, USA.

Background and aims: Patients (pts) with type 2 diabetes (T2D) on oral anti-hyperglycaemic medications (OAMs) and exenatide (Ex) may encounter progressive metabolic deterioration requiring additional treatment. Intensification of therapy with insulin added to OAM(s) plus Ex has not been previously reported. The primary aim of this study was to determine if insulin lispro protamine suspension (ILPS) is noninferior to glargine (G) in change in HbA_{1c} when added to OAMs plus Ex in adults with suboptimally controlled T2D.
Materials and Methods: This open-label, multicenter, randomised, 24-week clinical trial enrolled pts with T2D (BMI ≤45 kg/m^2, HbA_{1c} ≥7.0% and ≤10%) who had been treated ≥3 months with 1 or 2 OAMs (metformin ± sulphonylurea or pioglitazone) and Ex (10 µg twice-daily). Pts were randomly assigned to receive either ILPS (n=171) or G (n=168) at bedtime added to pre-study OAM(s) and Ex. Insulin was titrated from 6 units daily, using dosing algorithms to achieve fasting plasma glucose (FPG) targets 4.4-5.5 mmol/l for ILPS and 4.1-5.5 mmol/l for G. Statistical analysis was performed based on intent-to-treat population using last observation carried forward method. Prespecified noninferiority margin was 0.4%.
Results: Baseline demographics (age 56 years; T2D duration 9.9 years; weight 102 kg; BMI 34.9 kg/m^2) and disease characteristics (table) were similar across treatment groups. At 24-week endpoint (table), least squares mean difference in HbA_{1c} change between treatment groups (ILPS minus G) was 0.22% (95% CI: 0.06 to 0.38), demonstrating noninferiority of ILPS to G. However, mean reduction in HbA_{1c} was statistically less for ILPS-treated patients than G-treated pts. Percentage of pts who achieved HbA_{1c} <7.0% was not significantly different between treatment groups. Endpoint FPG was similar between treatment groups. Insulin dose was lower for ILPS vs G. Overall and severe hypoglycemic rates were similar in both groups but nocturnal hypoglycaemia rate was higher in ILPS- vs G-treated pts. Weight gain, <1 kg, was similar between treatments. Serious adverse events were infrequent and similar between groups.

Conclusion: ILPS is noninferior to G for change in HbA_{1c}. Compared to G, ILPS-treated pts had higher nocturnal hypoglycaemia rates, but similarly low overall and severe hypoglycaemia and minimal weight gain over the 24-week study duration. This is the first study demonstrating that addition of ILPS or G as treat-to-target basal insulin is an effective option for improving glycaemic control in pts with suboptimally controlled T2D treated with OAM(s) and Ex.

	ILPS (n=171)	Glargine (n=168)	p-value
Baseline HbA_{1c} (%)	8.20 ± 0.77	8.23 ± 0.80	0.888
Endpoint HbA_{1c} (%)	7.04 ± 0.81	6.83 ± 0.78	0.008

Basal insulin NPH, glargine and detemir in type 2 diabetes: hepatospecificity, effects on glucose and lipid metabolism, and pancreatic islet alpha and beta cell rest: a PK-PD study

P. Lucidi, P. Rossetti, F. Porcellati, P. Candeloro, P. Cioli, S. Marzotti, A. Marinelli Andreoli, R. Fede, G.B. Bolli, C.G. Fanelli;
Internal Medicine, University of Perugia, Italy.

Background and aims: To compare pharmacokinetics (PK) and pharmacodynamics (PD) of insulins NPH, glargine (Gla) and detemir (Det).
Materials and methods: 18 persons with type 2 diabetes (age 60±7 yrs, known diabetes duration 12.8±7.5 yrs, BMI 29.1±3.2 kg/m^2, A1C 7.5±0.6%, treatment insulin+OHA) (mean±SD) were studied after 1-week treatment with either NPH, Gla or Det 1/day (at 10 pm). Plasma glucose (PG) was clamped at 100 mg/dl for 32 h after s.c. injection of 0.4 U/kg at 10 pm (randomized, single-blind, crossover study). The primary endpoint was the glucose infusion rate (GIR) over 0-32 h (AUC_{0-32h}).
Results: All 18 persons completed the Gla study, but 2 persons on NPH and 3 on Det, interrupted the study because PG >150 mg/dl. The target PG was best achieved by Gla, followed by NPH and Det (102±2, 108±15, 108±14 mg/dl, p<0.05). However, PG increased overnight with NPH to a peak (119±18 mg/dl) at 07.00 h (NPH vs Gla and Det, p<0.05). The GIR AUC_{0-32h} was greater for Gla vs Det and NPH (1538±688, 1081±785, 1170±703 mg/Kg, p<0.05). Plasma insulin peaked with NPH at 05.00h and then decreased (peak 95±46, 32h 44±24 pmol/l), whereas it decreased less with with Gla (peak at 07.00h 108±42, 32h 61±30 pmol/l). Det (bound+free) had a plateau of ~1.800 pmol/l between 6-10 am followed by relatively faster decrease vs Gla. Gla suppressed endogenous glucose production more than NPH and Det (p<0.05), with no effect on glucose utilization. Glucagon was lower with Gla vs Det by 10% (p<0.05) likewise C-peptide with Gla vs Det and NPH (-17% and -12%) (p<0.05). FFA were higher with Det vs Gla by 22% and NPH by 15% (p<0.05) likewise ketones vs Gla (41%) and NPH (20%) (p<0.05).
Conclusion: All 3 basal insulins have similar hepato-specific effects, but there is no unit-to-unit equivalence on glucose-lipid metabolism. NPH is limited by nocturnal peak and decreased PK/PD at dawn. Det and Gla are superior to NPH for overnight-morning PG control, but Det is less potent than Gla and NPH in the afternoon. Each basal insulin should be used according to its PK/PD.

981

Mechanism for the differential effect of the long-acting insulin analog detemir on weight in patients with type 1 diabetes

S. Zachariah[1], B. Sheldon[1], F. Shojaee-Moradie[2], N. Jackson[2], K. Backhouse[2], S. Johnsen[3], M. Umpleby[2], D. Russell-Jones[1];
[1]Diabetes and Endocrinology, Royal Surrey County Hospital, [2]Diabetes and Endocrinology, Postgraduate Medical school, Guildford, [3]Surrey Clinical Research Centre, Guildford, United Kingdom.

Background: The acylated long-acting insulin analog detemir appears to lack the usual propensity for insulin to cause weight gain. Possible mechanisms include insulin detemir's predominant action on liver giving it a more physiological profile as well as a direct and indirect effect on appetite. Elucidation of the mechanism(s) of weight sparing with insulin detemir could provide valuable insights into the cause of insulin induced weight gain.
Research, design and methods: A single-centre, 32 week, open-label randomized crossover design trial was undertaken in 23 subjects (14 men, age 36.8 ±10.6 years, BMI 28.0 ±3.6 kg/m2) (mean±SD) with type 1 diabetes. Patients on a basal-bolus regime (with insulin aspart as bolus insulin) were randomized to receive either insulin detemir or NPH insulin as basal insulin for 16 weeks, followed by a switch to the other basal insulin for 16 weeks. At the end of each 16 week period the following were measured: total energy expenditure (by double labelled water), resting energy expenditure and diet induced thermogenesis (by indirect calorimetry), activity energy expenditure, (with an Actiheart monitor) and energy intake (by a 7 day food diary). Weight change, glycemic control, hypoglycemic episodes and hormones that affect satiety/fuel partitioning were also measured. Following a standard meal (600 kcals), serial measurements of GLP-1, ghrelin, pancreatic polypeptide and peptide YY were undertaken for 180 minutes. Statistical analysis was done using a general linear mixed model, and it was modified to include additionally a repeated measure effect for the times of measurement of the metabolic hormones.
Results: After 16 weeks of treatment, the weight change was -0.69 ± 1.85 kg with insulin detemir and +1.7 ± 2.46 kg with NPH (p=0.0006).Total energy expenditure was not different with insulin detemir compared to NPH insulin (p=0.334) but total energy intake was significantly less with insulin detemir (2016± 501 kcal/day) than NPH insulin (2181± 559 kcal/day) (p=0.026). There was no significant difference in HbA1c or the number of hypoglycemic episodes. Statistical modeling showed there was no relationship between HbA1c or hypoglycemia and weight change. Leptin was significantly lower with insulin detemir (9.45±7.29 ng/ml) compared to NPH insulin (10.83±9.15 ng/ml, p=0.039). Resistin was significantly higher with detemir compared to NPH insulin treatment (12.10±9.43 ng/ml vs. 9.28±4.13 ng/ml, p=0.047). There was no difference in adiponectin and IGF-1. Following the meal, ghrelin (610.9 pg/ml vs. 528.39 pg/ml, p=0.002) and pancreatic polypeptide (813.4 vs. 777.13 pg/ml, p=0.001) were significantly higher with insulin detemir compared to NPH treatment. There was no difference in GLP-1 and PYY levels.
Conclusion: Insulin detemir caused less weight gain in type 1 diabetes patients compared to NPH insulin. This study suggests this is due to reduced energy intake rather than an increase in energy expenditure. This may be mediated by a direct or indirect effect of insulin detemir on hormones that control satiety.

PS 91 Body and soul: the psychological aspects of diabetes

982

Psychological distress predicts the development of the metabolic syndrome: a prospective, population-based study

P.J. Puustinen[1], H. Koponen[1], H. Kautiainen[2,3], P. Mäntyselkä[1], M. Vanhala[1,2];
[1]Institute of Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, [2]Unit of Family Practice, Central Hospital of Middle Finland, Jyväskylä, [3]ORTON, Rehabilitation Unit, Helsinki, Finland.

Background and aims: To prospectively examine the association of psychological distress with the development of metabolic syndrome (MetS) and the role of potential mediators (demographic characteristics, health behaviors and inflammation) in this association.
Materials and methods: A total of 466 (185 male and 281 female) subjects, aged 36 to 56 years and free of MetS at baseline, participated in a population-based study from 1997-1998 and again from 2004-2005. Mean observation time was 6.4 years. Various clinical, biochemical and behavioral factors were measured at baseline, including assessment of psychological distress using the 12-item General Health Questionnaire (GHQ-12). The development of MetS was measured at follow-up based on National Cholesterol Education Program (NCEP) criteria.
Results: Subjects with high psychological distress at baseline (GHQ score 4-12) were more than twice as likely to develop MetS than those with low psychological distress (OR 2.18, 95% CI 1.30 to 3.64). Adjustments for age and gender, health behaviors (smoking, alcohol use and leisure time physical activity) and C-reactive protein (CRP) in the analysis diminished the odds of developing MetS in the distressed group (OR 1.87, 1.82 and 1.80, respectively); however, the association remained statistically significant (p=0.022 - 0.037).
Conclusions: Psychological distress at baseline increases the risk of developing MetS during follow-up. This association remained robust after adjusting for age, gender, baseline health behaviors and CRP. These prospective findings are evidence of a significant association between psychological distress and the development of MetS. Thus, effective treatment of psychological distress may reduce the incidence of MetS.

TABLE 1. Logistic Regression Models for the Metabolic Syndrome across Follow-up (Odds Ratios, 95% Confidence Intervals, p-values). Models Include Psychological Distress, Age, Gender, Health Behaviors and C - reactive Protein.

	Odds ratio (95% CI)	p-value
Psychological distress (GHQ-12)		
Low (0-3)	1 (reference) †	
High (4-12)	1.80 (1.04 to 3.12)	0.037
Age, per year	1.09 (1.05 to 1.14)	<0.001
Gender		
Female	1 (reference) †	
Male	1.02 (0.64 to 1.65)	0.92
Current smoker	1.77 (1.05 to 2.99)	0.032

A matched case-control study of depressive symptoms in type 2 diabetes

W.A. Davis[1], M. Hunter[2], K. Peters[1], T.M.E. Davis[1];
[1]School of Medicine and Pharmacology, University of Western Australia, Fremantle, [2]Busselton Health Study, University of Western Australia, Busselton, Australia.

Background and aims: Diabetes and depression are important co-morbid conditions. Patients with diabetes are 1.5-2 times more likely to have depression compared with people without diabetes, although this risk is attenuated after adjustment for age, sex and cardiovascular disease (CVD). Risk factors for depression include both clinical and personal factors, and there is some evidence that psychiatric conditions including depression are more common in rural vs. urban environments. We conducted an age- and sex-matched case-control study to elucidate the relationship between type 2 diabetes and depression in a rural setting.
Materials and methods: In 2009, residents of Busselton Shire in the south-west of Western Australia who had been diagnosed with diabetes and randomly selected age- and sex-matched normoglycaemic residents were invited for a comprehensive assessment. In addition to medical history, examination and biochemical testing, participants completed the Personal Health Questionnaire Depression Scale (PHQ-9). Paired tests were used to compare potential associates of depression between cases and controls. Multiple logistic regression was used to determine independent associates of prevalent depression.
Results: We assessed 172 adults with type 2 diabetes and 172 controls. Half (51.2%) were male. Cases and controls did not differ significantly in age (70.7±10.4 vs. 71.0±10.0, P=0.80), but cases had significantly higher mean body mass index (BMI) than controls (30.4±5.3 vs. 27.0±4.0, P<0.001) and higher prevalence of self-reported CVD, exertional chest pain, and current smoking habit. Those with diabetes had median duration of 8.9 [5.0-14.3] years; 35.7% were diet-treated, 46.8% were on oral treatment and 17.5% were using insulin. Those with type 2 diabetes were significantly more likely to have a current major or any depressive syndrome compared with those with normoglycaemia (5.9% vs. 0.6%, P=0.012, and 11.8% vs. 4.1%, P=0.019, respectively), but were no more likely to have been prescribed antidepressant therapy (11.6% vs. 12.6%, P=0.86). The majority (22/25 or 88.0%) of normoglycaemic subjects with any depressive syndrome and/or taking antidepressants were being treated for depression compared with less than two-thirds (20/35 or 57.1%) of those with type 2 diabetes. BMI, current smoking habit and exertional chest pain but not diabetes status were independently associated with the presence of a) any depressive syndrome, and b) any depressive syndrome and/or antidepressant medication use. Age, sex, income, marital status, born overseas, education, alcohol intake, and self-reported CVD were also not associated with depression.
Conclusion: Depressive syndromes, especially major depression, were significantly more prevalent in rural-dwelling Australian adults with type 2 diabetes compared with age- and sex-matched normoglycaemic controls, but those with diabetes were less likely to be treated for depression. The higher prevalence of depressive syndrome in adults with type 2 diabetes compared with normoglycaemic adults may be explained largely by their significantly higher BMI.

Depression, glycaemic control, and physical activity in a multi-ethnic population screened for type 2 diabetes

L.V. Murray[1], E.G. Wilmot[1], M.J. Davies[1], T. Yates[1], K. Khunti[2];
[1]Cardiovascular Sciences, [2]Health Sciences, University of Leicester, United Kingdom.

Background and aims: Individuals with type 2 diabetes mellitus (T2DM) suffer from higher levels of diagnosed depression and depressive symptoms compared to healthy controls. Evidence also exists for this relationship in individuals with impaired glucose regulation (IGR), defined as impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT). It is unclear whether this association is related to lifestyle factors such as physical activity (PA) or pathophysiological changes related to insulin resistance. Previous studies have shown an association between depression and PA levels, and individuals with T2DM and IGR are less physically active than healthy controls. We hypothesised that glucose regulation is associated with depression, independent of PA levels.

Materials and methods: Participants were identified from general practices in Leicestershire (UK), using the Leicester Diabetes Risk Score. Individuals attended a baseline screening visit that involved questionnaires, blood samples and clinical assessment. Glucose status was assessed using the Oral Glucose Tolerance Test. Depression status was assessed using the Hospital Anxiety and Depression Scale (HADS). Participants wore a pedometer for a 7 day period to objectively measure PA levels. SPSS v.16 was used to calculate means (± s.d.) and correlation coefficients. ANOVA and chi squared tests assessed differences between groups.
Results: 926 individuals (38.4%female) were screened; 88.6% White European and 11.4% Black and Minority Ethnic. Mean age was 63 years (±8.3); 25.7% had screen-detected IGR and 4.4% had screen-detected T2DM. Mild-severe depression was detected in 9.6% of screened individuals and 17.8% reported a history of depressive illness. Mean steps per day was 6801 (±3202). Mild to severe depressive symptoms were more prevalent in individuals with screen-detected T2DM (19% vs. 12% with IGR vs. 9% with normal glucose tolerance (NGT), $p < 0.05$ for trend). Across the whole sample fasting glucose was weakly correlated with depression score when controlling for age, sex and ethnic origin ($r = 0.087$, $p < 0.05$), which was maintained after further controlling for PA levels ($r = 0.083$, $p < 0.05$). In addition, fasting glucose was higher in those with moderate-severe depressive symptoms, compared to those without depressive symptoms (mean difference = 0.48mmol/l, p = < 0.05). No significant associations were found between depression score and 2-hour glucose or HbA1c. In participants with screen-detected IGR, fasting glucose was more strongly correlated with depression score when controlled for age, sex and ethnic origin ($r = 0.247$, p = < 0.01), which was maintained after further controlling for PA levels ($r = 0.269$, $p < 0.01$). Those with IGR performed significantly less steps/day than individuals with NGT (mean difference = -850 steps, $p < 0.01$).
Conclusion: This study reveals a positive association between depression score and fasting glucose, independent of PA levels, in individuals that are unaware of their glycaemic status. This suggests that the higher levels of depression seen in those with T2DM are not simply due to the impact of living with a chronic illness or to the low levels of PA seen in this group. We did not observe an association between depression score and 2-hour glucose or HbA1c, suggesting that the mechanisms underlying IFG may be more related to depression than those relating to IGT.

Interaction between depressive symptoms and illness representations in predicting self-care behaviours in type 2 diabetic patients
M. Pibernik-Okanovic, D. Ajdukovic, Z. Metelko;
Outpatient Clinic, Vuk Vrhovac Institute, Zagreb, Croatia.

Background and aims: Predictive value of illness representations including seriousness, treatment effectiveness and control, on multiple diabetes outcomes has been well established. This study aimed to determine how depressive symptoms interacted with personal model's domains in predicting eating behaviour, physical activity, blood glucose self-monitoring and foot care in type 2 diabetic patients.
Materials and methods: A randomly selected sample of 172 type 2 outpatients (55% female, aged 63±8, educated for 10.5±4 yrs., with diabetes duration of 10±8 yrs., 29% insulin-treated, with 6.5%±0.9 HbA1C and 30±4 kg/m2 BMI) was interviewed for psychological anamnesis and examined for depressive symptoms and personal model of diabetes. Respondents' mood and illness representations were assessed by The Patient Health Questionnaire-Depression (PhQ-9) and the 8-item Personal Model of Diabetes Questionnaire (PM), and their self-care behaviours were approximated by the Summary of Diabetes Self-Care Activities (SDSCA). Participants were divided into three groups: without depressive symptoms (PhQ<5), with minimal symptoms (PhQ=5-9) and with moderate to severe depressive symptoms (PhQ≥10), which were compared as to personal model, self-reported self-care and disease-related characteristics. Kruskal-Wallis ANOVA was used to compare psychological and disease-related variables in the groups with different depressive symptom levels, and ordinal multinomial regression model to determine to what degree depressive symptoms and personal model of diabetes predicted particular self-care behaviours.
Results: Minimal depressive symptoms were reported by 20% of the patients, and moderate to severe symptoms by another 9%. No differences in age, diabetes duration, type of therapy, HbA1C and BMI were found between the non-depressed group and patients with depressive symptoms (all p>0.05). Self-reported eating behaviour, exercise and foot care were comparable across the groups (all p>0.05). Blood glucose self-monitoring was most frequent in patients with minimal depressive symptoms, followed by the non-depressed and moderately to severely depressed ones (H=5.80 p=0.05). Diabetes impact on daily life as measured by PM was reported greater by both depressed groups as compared to the non-depressed one (H=6.18 p=0.04), while other domains - seriousness, diabetes control and prevention of complications - did not differ across the groups. Non-linear regression model indicated that the control beliefs independently predicted patients' eating behaviour and physical activity as measured by SDSCA (Wald Stat=9.3 p=0.002 and Wald Stat=7.4 p=0.006, respectively). Foot care was predicted by seriousness beliefs (Wald Stat=4.6 p=0.03), while depressive symptoms were the only independent predictor of blood glucose self-monitoring (Wald Stat=7.9 p=0.01).
Conclusion: Even mild depressive symptoms were found to be associated with illness representations in type 2 diabetic patients, implying a more highly perceived impact of diabetes on daily activities. Beliefs that self care controlled diabetes were the best predictors of eating behaviour and exercise, while feelings about diabetes seriousness and worry predicted foot care. Depressive symptoms rather than personal model domains predicted blood glucose self-monitoring, showing a positive effect in mild depressive symptoms and adverse in moderate to severe ones.

Pain self-efficacy and pain catastrophising predict depression in people with painful diabetic neuropathy
B.E. McGuire[1], M. Treacy[1], K. Sarma[1], S. Dinneen[2], T. O'Brien[2], F. Dunne[2];
[1]Psychology, [2]Medicine, National University of Ireland, Galway, Ireland.

Background and aims: Neuropathy is one of the most common and troublesome complications of diabetes and neuropathic pain can result in significant morbidity and reduced quality of life. The objective of the study was to investigate whether pain self-efficacy (belief in one's ability to function, despite pain) and pain catastrophizing (fearful and anxious thoughts about pain) influenced depression levels in those with painful diabetic neuropathy.
Materials and methods: We identified a sample of 138 patients with painful diabetic neuropathy on the basis of database recordings and issued a postal survey pack including a measure on pain (Brief Pain Inventory - BPI), pain self-efficacy (Pain Self-Efficacy Scale - PSE), pain catastrophizing (Pain Catastrophizing Scale - PCS), and depression (Hospital Anxiety and Depression Scale - HADS).
Results: We received responses from 62 patients (45% response) of mean age 54 years; 79% had Type 2 diabetes. Depression "caseness" on the HADS was reported by 55% of respondents. There was a statistically significant negative correlation between Pain Self-Efficacy and Depression (r=-.54, p≤.005) and a significant positive correlation between Pain Catastrophizing and Depression (r=.511, p≤.005). When applied as a predictive model of depression, together Self Efficacy and Catastrophizing were moderately associated with Depression (Multiple R=.56) and predicted 33% of this variable's variance. The standardised regression coefficients suggest that Self Efficacy (β=-.357) is a stronger predictor of Depression than total Pain Catastrophizing score (β=.259).
Conclusion: The results indicate that severity of depression in those with diabetic neuropathic pain is predicted by a lower sense of control over the pain (as indicated by Self Efficacy measure) and is also predicted by a tendency to think about the pain in an unhelpful way (as indicated by the Pain Catastrophizing Scale). The results highlight a role for cognitive-behavioural interventions to assist patients with diabetes in coping with neuropathic pain.

Association of self-reported hypoglycaemia and quality of life and depression among adults with type 2 diabetes mellitus
S. Grandy[1], H.W. Rodbard[2], K.M. Fox[3], J.R. Gavin III[4], E. Hardy[1], SHIELD Study Group;
[1]AstraZeneca Pharmaceuticals LP, Wilmington, [2]Endocrine and Metabolic Consultants, Rockville, [3]Strategic Healthcare Solutions, LLC, Monkton, [4]Emory University, Atlanta, USA.

Background and aims: This study examined the association of hypoglycemia with quality of life and depression among adults with type 2 diabetes mellitus (T2DM) with and without hypoglycemia.

Materials and methods: Respondents to the 2008 U.S. Study to Help Improve Early evaluation and management of risk factors Leading to Diabetes (SHIELD) survey were asked the number of times they experienced hypoglycemia in the past 4 weeks and past 12 months. Respondents also completed the Short Form-12 (SF-12) quality-of-life questionnaire and the Patient Health Questionnaire (PHQ-9) depression questionnaire. T2DM respondents reporting at least 1 hypoglycemia (low blood sugar) episode were compared with T2DM respondents who did not report hypoglycemia in the previous 12 months.
Results: There were 3,000 respondents with T2DM, and 2,718 (91%) completed the SF-12 and PHQ-9; 23% reported experiencing hypoglycemia in the past 12 months. Respondents reporting at least 1 hypoglycemic episode (n = 627) had significantly lower (p<0.001) SF-12 scores for both physical health (PCS) (mean ± SD: 37.4 ± 12.7 vs. 40.9 ± 12.7) and mental health (MCS) (50.1 ± 11.7 vs. 52.4 ± 10.1) compared with those without hypoglycemia (n = 2,091). Mean PCS scores decreased as the number of hypoglycemia episodes increased: PCS 39.0± 14.4 for 1 episode, 38.3 ± 12.0 for 2-3 episodes, 38.1 ± 13.3 for 4-5 episodes, and 35.1 ± 12.6 for ≥6 episodes (p = 0.03). Mean MCS scores did not differ by across these same groupings (p = 0.09). Mean PHQ-9 scores were significantly higher (p <0.001) among respondents reporting hypoglycemia (5.2 ± 5.8), compared with respondents who did not report hypoglycemia (3.9 ± 5.0), indicating greater depression burden. Significantly more respondents experiencing hypoglycemia (10.1% ± 3.8%) reported moderately severe to severe depression (PHQ-9 scores ≥15), compared with respondents without hypoglycemia (5.1% ± 2.1%). Mean PHQ-9 scores increased as the number of hypoglycemia episodes increased: score 4.1 ± 4.9 for 1 episode, 4.9 ± 5.7 for 2-3 episodes, 5.7 ± 6.3 for 4-5 episodes, and 6.0 ± 6.0 for ≥ 6 episodes (p = 0.01).
Conclusion: T2DM respondents experiencing hypoglycemia report a lower quality of life, in the domains of both physical and mental health, and greater burden of depression than respondents without hypoglycemia. These findings suggest that hypoglycemia and depression need to be considered together in routine clinical practice settings.

Can affects and self image affect diabetes mellitus?
E.O.M. Melin[1], M. Landin-Olsson[1], H.O. Thulesius[2];
[1]Department of Clinical Sciences. Lund University, Lund, [2]Division of Family Medicine, Department of Clinical Sciences. Lund University, Malmö, Sweden.

Background and aims: Depression is common in patients with DM and associated with impaired metabolic control and increased risk of all diabetic complications. Other types of psychological and psychosomatic factors involved in DM morbidity are not so well investigated. Our aims in this study were to explore depression, anxiety, alexithymia and self image and their correlations with HbA1c among young and middle aged patients with DM. Alexithymia was here defined by three factors: Difficulties Identifying Feelings (DIF), Difficulties Describing Feelings (DDF) and Externally Oriented Thinking (EOT). Self image was in this study composed of three positive factors: "self-affirm", "active self-love", "self-protect"; three negative factors: "self-blame", "self-attack", "self-neglect"; and two neutral factors reflecting autonomy: "self-emancipate" and "self-control".
Materials and methods: At a Swedish specialist outpatient clinic, 353 DM patients 18-59 years old (median age 42 years; 56% men, 44% women) participated in this study. Depression and anxiety were assessed by the Hospital Anxiety and Depression Scale (HAD), Alexithymia by the Toronto Alexithymia Scale-20 (TAS-20), and Structural Analysis of Social Behaviour (SASB) was used for assessing the eight factors of self image described above. We also measured waist circumference and determined Body Mass Index (BMI) for the 353 DM patients. We did bivariate correlation, linear regression, and combined variable correlations analyses with HbA1c as dependant variable.
Results: Mean HbA1C was 7.13 % (SD=1.37, N=353) and mean waist circumference 0.87 m (SD 0.13, N=339). An elevated anxiety score was found in 35% (111/320), a negative self image in 22% (69/309), alexithymia in 16% (51/318), and an elevated depression score in 12% (37/320) of the 353 DM patients. We found that 45% (N=144) of DM patients did not have any signs of depression, anxiety or alexithymia and had a normal self image score. Their mean HbA1c was 6.96 % (SD=1.18). Alexithymia had the greatest impact (p=0.037) and the combination with negative self image (p=0.035) was particularly severe. For 17 patients with a high alexithymia score, a negative self image, but with a normal depression score HbA1c was 7.82 % (SD=1.57). For 12 patients with a combination of a high alexithymia score, a negative self image and a high depression score HbA1c was 8.57 % (SD=1.78). For 46 women with a waist circumference of > 0.88 m the HbA1c was 7.92 %, and for 21 men with >1.02 it was 7.35%. Bivariate correlation between HbA1c and 17 variables showed a significant r below the 5% p-level for the following 8 variables: anxiety, depression, DIF, "self-control", "self-attack", "self-neglect", BMI, and waist circumference. Age, DDF, EOT, "self-emancipate", "self-affirm", "active self-love", "self- protect", "self-blame" and duration of DM showed no correlation with HbA1c. In linear regression analyses, including the 8 variables above, DIF (p<0.0001) and waist circumference (p<0.001) remained significantly associated with HbA1c.
Conclusion: In this study we show that alexithymia and negative self image had a greater impact on HbA1c levels than depression in patients with DM. Particularly, the alexithymia sub factor DIF (difficulties identifying feelings) correlated with HbA1c, and the waist circumference in a linear regression model.

Longitudinal motivational predictors of dietary self-care, life satisfaction and diabetes control in adults with newly diagnosed type 2 diabetes mellitus
A. Nouwen[1], T. Ford[2], A. Balan[1], J.W.R. Twisk[3], D.G. White[2];
[1]School of Psychology, University of Birmingham, United Kingdom, [2]School of Psychology, Staffordshire University, Stoke-on-Trent, United Kingdom, [3]Faculty of Earth and Life Sciences, Vrije Universiteit, Amsterdam, Netherlands.

Background and aims: Changing dietary habits is considered the most difficult part of diabetes self-management after being diagnosed with type 2 diabetes (T2DM). The tendency to overeat at diagnosis has been associated with weight gain and intake of energy four years after diagnosis. Therefore, better understanding of the motivational factors involved in adopting and maintaining dietary self-care activities during the critical period following the diagnosis of T2DM is needed. This study aimed to examine whether motivational factors from Social-Cognitive Theory (self-efficacy, positive and negative outcome expectancies and self-evaluation) and Self-Determination Theory (autonomous self-regulation and autonomy support) are associated with the course of dietary self-care, life satisfaction and diabetes control in a sample of people newly diagnosed with type 2 diabetes.
Materials and methods: Participants, 237 people (65% male) newly diagnosed with type 2 diabetes, completed questionnaires assessing perceptions of support from health care professionals fostering autonomy, autonomous motivation, dietary self-efficacy, positive and negative outcome expectancies, self-evaluation, dietary self-care, life-satisfaction and diabetes knowledge at five occasions, each three months apart. BMI and HbA1c were also assessed on each occasion.
Results: Multivariate analyses, using Generalised Estimating Equations (GEE), showed that autonomous motivation ($\beta = 0.06$, $p < 0.05$), dietary self-efficacy ($\beta = 0.006$, $p < 0.001$), and self evaluation ($\beta = 0.23$, $p < 0.001$) were significantly associated with the course of dietary self-care, even when adjusted for demographic and illness-related variables. The course of life satisfaction over the 18-month period was significantly associated with self-efficacy ($\beta = 0.008$, $p < 0.01$), and positive ($\beta = 0.005$, $p < 0.01$) and negative outcome expectancies ($\beta = -0.002$, $p < 0.01$), while changes in HbA1c were significantly associated with self-efficacy ($\beta = -0.007$, $p < 0.05$), and negative outcome expectancies ($\beta = -0.005$, $p < 0.01$). However, for the latter two analyses, self-efficacy was no longer a significant predictor after controlling for a number of demographic and illness-related variables.
Conclusion: Together with self-efficacy and autonomous motivation, self-evaluation is an important motivational construct associated with dietary self-care over the first 18 months after diagnosis of T2DM. Whether people newly diagnosed with T2DM remain satisfied with their lives over that period depends on their positive and negative perceptions they have about their diabetes. Because HbA1c reflects diabetes control over the past 2-3 months, the significant longitudinal association with negative outcome expectancies is likely to indicate poorer control of diabetes leading to more negative perceptions of diabetes. In teaching how to cope with newly diagnosed T2DM, health care professionals may want to include specific interventions targeting these motivational constructs.

990

The association of screening anxiety with fasting and 2-hour plasma glucose, and HbA_{1c}

N. Aujla[1], M.J. Davies[2], T.C. Skinner[3], D.R. Webb[1], B. Srinivasan[1], K. Khunti[1]; [1]Health Sciences, University of Leicester, United Kingdom, [2]Cardiovascular Sciences, University of Leicester, United Kingdom, [3]Combined Universities Centre for Rural Health, Geraldton, Australia.

Background and aims: Previous work has identified that feelings of stress can result in hyperglycaemia, which may become problematic during diabetes screening involving Oral Glucose Tolerance Tests (OGTTs). OGTTs are currently the 'gold standard' approach for screening for diabetes, and involve collection of both fasting and 2-hour plasma samples. Some research has identified that for diabetes screening, anxiety may be intensified in people with negative perceptions about the condition being life-threatening and resulting in complications. Importantly, research has not yet explored the extent to which raised anxiety levels can affect glucose results obtained from OGTTs. HbA1C has recently been suggested for use as a diagnostic test for diabetes. The aim of this study was to investigate associations between anxiety and fasting and 2-hour plasma glucose levels collected from OGTTs, and HbA1C.
Materials and methods: In a community screening study, 4688 White-European (WE, 40-75 years) and 1353 South-Asian participants (SA, 25-75 years) without a previous diagnosis of Type 2 Diabetes Mellitus (T2DM) underwent an OGTT, HbA1C, full lipid profile, detailed history, anthropometric measurements and completed the short-form Spielberger State Trait Anxiety Inventory. Data was analysed with means and standard deviations (for continuous variables) and percentages (for categorical variables). Pearson's correlation coefficient was computed to identify relationships. Linear modelling was conducted to further explore associations, with adjustment for confounding factors.
Results: Overall prevalence of T2DM and Impaired Glucose Regulation (IGR) was 3% and 16%, respectively. Anxiety levels were significantly higher in SA (mean 34.1; SD 0.37) compared to WE participants (mean 29.8; SD 0.13). Fasting glucose levels (mean 5.3mmol/l; SD 0.9, p=0.001) and HbA1C (mean 5.9%; SD 0.62, p<0.001) were also significantly higher among SA participants. Significant correlations were not identified between fasting (r -0.005, p=0.75) or 2-hour glucose levels (r -0.10, p=0.24) and HbA1C (r 0.01, p=0.40). Statistically non-significant associations of anxiety with fasting glucose and HbA1C remained following adjustment for age, gender or ethnicity.
Conclusion: This study found that anxiety levels at screening were heightened among people of SA ethnicity. In addition, the study found that fasting and 2-hour plasma glucose levels and HbA1C are not affected by anxiety during screening tests for diabetes. Therefore, current and proposed screening methods are not affected by anxiety at screening.

Patient-centered outcomes and glycaemic variability in type 1 and type 2 diabetes: a cross-over trial of insulin glargine + glulisine vs premix analogue insulin

M.A. Testa[1], L. Blonde[2], J. Gill[3], R.R. Turner[4], D.C. Simonson[5]; [1]Biostatistics, Harvard School of Public Health, Boston, [2]Endocrinology, Ochsner Medical Center, New Orleans, [3]sanofi-aventis, Bridgewater, [4]Phase V Technologies, Wellesley, [5]Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital, Boston, USA.

Background and aims: Intensive insulin therapy with multiple daily injections (MDI) offers superior glycemic control; however, regimen burden and hypoglycemia remain barriers to acceptance. The primary objective of this study was to test for superiority in improvements from baseline in patient-centered outcomes of patient satisfaction (PS) and quality of life (QoL) in subjects with type 1 or type 2 diabetes when treated with insulin glargine plus premeal rapid acting insulin glulisine versus treatment with premix analogue insulin. The secondary objectives were to compare glycemic control and variability between the two insulin regimens.
Materials and methods: We studied 388 insulin-treated patients (82 T1DM, 306 T2DM, 47% male, age 54±11 yrs, HbA1c 7.8±0.7%) who were randomized to either open-label daily insulin glargine plus premeal glulisine (GG; n=192) or BID premix 75/25 or 70/30 (PM; n=196) for 12 wks (P1), and then crossed over to the alternate treatment arm for an additional 12 wks of treatment (P2). Patients followed an insulin titration algorithm with a target HbA1c < 7.0% with the aid of an electronic diary transmitting data daily to a web-based remote monitoring system. Clinic personnel reviewed daily 4-point glucose readings, insulin dosages, hypoglycemia, other symptoms, and adverse events, and called the patient weekly to provide insulin dosing recommendations. Patients completed clinic-based PS and QoL questionnaires at Wks 0, 8, 12, 20 and 24, and underwent continuous glucose monitoring (CGM) for three-day periods at Wks 0, 12 and 24.
Results: Mean±SE HbA1c change for GG vs PM was -0.53±0.10% vs -0.20±0.10% for P1, and -0.25±0.10% vs +0.10±0.10% for P2 (both p<0.0001). At P1 Wk 12, 55% of GG reached HbA1c <7.0% vs 31% for PM (p<0.0001), with no differences in serious adverse events (5.4 vs 4.9%, p=0.7) or daytime or nocturnal hypoglycemia. Combined linear, mixed model P1 and P2 baseline-adjusted Wk 12 mean±SE estimates are reported for PS, QoL and CGM. The PS Net Benefit scale (0-100) improved from 51.1 to 60.5±1.2 for GG, but worsened to 45.4±1.2 for PM (p<0.0001). Overall QoL favored GG by 0.13±0.04 Z-score units (p<0.001). All 4 Net Benefit subscales favored GG (p<0.0001). The PS Regimen Acceptance scale was comparable (67.3±0.5 for GG vs 66.5.±0.5 for PM, p=0.33) with 3 lifestyle and side effects subscales favoring GG (p<0.001) and 3 convenience subscales favoring PM (p<0.02). QoL scales favoring GG vs PM were perceived health, symptom distress (both p<0.0001), general health perceptions (p<0.01) and psychosocial (p<0.02). Emotional and cognitive scales were comparable. CGMS daily mean, daily SD and % time > 7.8 mmol/l were lower for GG than PM by 0.7±0.1 mmol/l, 0.3±0.07 mmol/l and 7.3±1.6% respectively (all p< 0.0001), with no difference in CGM % time < 3.9 mmol/l (p=0.10).
Conclusion: Patient perception of net benefit and treatment satisfaction was more heavily weighted by the beneficial changes in health status and quality of life associated with improvements in glycemic control and reduced variability with insulin glargine plus premeal insulin glulisine than by the burden of additional daily insulin injections.

PS 92 The heterogeneity of diabetes

992

Clinical heterogeneity of type 1 diabetes mellitus at onset

Z. Huang[1], Y. Chen[2], F. Li[3], Y. Li[1];
[1]Department of Endocrinology and Diabetes Center, The First Affiliated Hospital of Sun yat-sen University, Guangzhou, [2]Department of Endocrinology, Guangzhou No.458 Hospital, [3]Department of Internal Medicine, Traditional Chinese Medical Hospital of Gaoming County, Foshan, China.

Background and aims: Retrospective analysis was performed in 489 consecutive patients with discharge diagnosis of type 1 diabetes (T1DM) between 1999 and 2009 in our hospital to examine the clinical heterogeneity of the disease.
Materials and methods: A total of 205 out of 489 patients were newly onset T1DM. In these patients, clinical characteristics and laboratory data at onset were compared among fulminant type 1 diabetes (FT1DM, diagnostic criteria according to Imagawa et al.) and those with duration of symptoms before diagnosis shorter (acute-onset) or longer (slow-onset) than 3 months. One-way ANOVA and multivariate chi square were employed to compare the differences among groups.
Results: The proportions of FT1DM (n=18), acute-onset (n=137) and slow-onset (n=50) T1DM were 8.8%, 66.8%, 24.4% respectively. The onset of FT-1DM was so abrupt that the concentration of plasma glucose was prominently elevated, whereas $HbA1_C$ was disproportionately near normal, and the duration of symptoms before diagnosis was extremely shorter than the other two groups. More female patients tended to develop FT1DM, and flu-like symptoms (44.4% vs 22.6%, 18%) were more frequently observed in this group, but the differences failed to reach significance. Two patients who developed T1DM during or after pregnancy belonged to the FT1DM group. Ketoacidosis was almost inevitable phenomenon at diagnosis and the accompanied metabolic derangement (hyponatremia, acidosis, dysfunction of kidney and liver etc) was more severe in FT1DM group. The acute-onset T1DM constituted the maximum ratio of the disease, and patients were with the youngest age at onset and with the leanest somalotype before diagnosis. Patients with slow-onset type were relatively older and had greater body mass index but lost more weight at diagnosis. The fasting as well as post-load C-peptides in this group were relatively higher, and ketoacidosis at onset was less likely.
Conclusion: Clinical heterogeneity in the three groups was apparent, which might indicate different trigger mechanisms, especially the impacts of virus infection, feminine hormones or state of pregnancy on the extent of β cell damage as well as the development of T1DM, more so the fulminant type.
Table 1 Comparisons of clinical features of FT1DM, acute-onset and slow-onset T1DM.

Table 1 Clinical features of FT1DM, acute-onset and slow-onset T1DM.

Items	Fulminant	Acute-onset	Slow-onset	P value

Ketosis prone diabetes in south London - are we discontinuing insulin appropriately?

M.S.B. Huda, R. Maitland, S.R. Henderson, O. Poole-Wilson, J. Miell, S.R. Kottegoda;
Department of Diabetes & Endocrinology, University Hospital Lewisham, London, United Kingdom.

Background and aims: Ketosis prone diabetes is a common, but frequently unrecognised presentation of diabetes in an African/Caribbean population. An ideal approach to insulin discontinuation in these patients is unclear. We examined rates of insulin discontinuation, initial management and subsequent follow up in a large cohort of patients from a south London population.
Materials and methods: Patients that presented with diabetic ketoacidosis (DKA) or unprovoked ketosis (defined as ≥2+ ketones on urine dipstick) between 2003 and 2009 to University Hospital Lewisham, London were identified from hospital notes and a clinic database. Those with known or a clear clinical new diagnosis of type 1 diabetes were excluded.
Results: 53 patients were identified; 28 with DKA and 27 with unprovoked ketosis. 36 (68%) were male. The median age was 41 (range 17-71). Mean±SEM body mass index was 30.1±1.3. The majority were African-Caribbean in origin (76%), with 8(15%) Caucasian patients and 5(9%) from the Indian subcontinent. Thirty-seven (70%) patients presented as a new diagnosis of diabetes. Forty-six (86%) patients were discharged on subcutaneous insulin. Twenty-eight (53%) had islet cell and GAD antibodies measured; only 2 patients had positive antibodies. Sixteen (30%) patients had fasting c-peptides measured; only 1 patient had a value <330pmol/l (value used to define adequate insulin secretory capacity in a previous large cohort). The mean follow up was 31±8.4 months (range 3- 120) and 39 (74%) were still on insulin. Five patients taking insulin experienced hypoglycaemia in the first three months, leading to insulin discontinuation in 2 cases. The mean time to insulin discontinuation was 13.1±3.0 months. Only one patient had a relapse of DKA seven years after discontinuing insulin. Mean HbA1c on admission was 12.3±0.6, decreasing significantly to 8.1±0.4 at follow-up (p<0.01). Body weight did not significantly increase over follow up (90.1±3.1 admission to 91.8±3.2 follow up p=0.66).
Conclusion: This is the first large cohort of ketosis prone diabetic patients described in a UK population. Our data show that the majority of patients are discharged on insulin and continue with insulin at follow up, which may explain the extremely low incidence of relapse in DKA .Patients have a significant decrease in HbA1c with minimal weight gain, suggesting a conservative approach to insulin withdrawal may be appropriate in this population.

994

Post-transplant diabetes mellitus and its impact on survival of liver transplant patients

X.Y. Chen[1], M.X. Yu[1], J. Zhou[2], J. Gao[3], X. Gao[1];
[1]Department of Endocrinology, [2]Department of Liver Surgery, [3]Department of Nutrition, Zhongshan Hospital, Fudan University, Shanghai, China.

Background and aims: Post-transplant diabetes mellitus (PTDM) has great effects on complications in relation to cardiovascular system, infections, neuropsychiatric system et al, resulting in greater morbidity and affecting graft survival and patients' long-term outcome. The aim of our study was to discuss the impact of PTDM on patient survival and long-term complications.
Materials and methods: Retrospective analysis 438 patients who performed orthotopic liver transplantation (OLT) in our center between April, 2001 and December 2008, patients with previous history of using steroids, or data not completed or died within 3 months after OLT were excluded. All patients were divided to PTDM (n=140) and non-PTDM (n=298) group according to fasting plasma glucose (FPG) after operation. We compared two groups on survival rate and complications after OLT, including sepsis, chronic renal insufficiency, fungal infection, biliary complication, CMV infection, fatty liver. Cox regression analysis was used to analyze those factors affecting patient survival. We used Chi-square test to compare qualitative variables and Kaplan-Meier method and log-rank test to analyze survival rate. P value less than 0.05 was considered statistically significant. Statistic analysis was done by SPSS 16.0.
Results: Cox regression analysis indicated that FPG before or after operation, tumor relapse or metastasis and renal insufficiency after OLT were independent risk factors for patients' death, while the hazard ratio of each factor was

1.57 (P=0.02), 1.84 (P<0.0001), 2.08 (P=0.0001) in PTDM group towards non-PTDM group. The mean survival time in PTDM group was 4.216±0.260 years, while non-PTDM group was 6.133±0.198 years, which showed statistic meaning between each group (P<0.01). Compared with non-PTDM group, PTDM group had higher rate in sepsis (151/298:87/140) (P=0.025) and chronic renal insufficiency (65/298:51/140) (P=0.001), and showed statistic meaning, while no difference were found in fungal infection, biliary complication, CMV infection and fatty liver (All P>0.05).
Conclusion: PTDM has great effect on patient's survival and complication after OLT, reduces patient's survival and raises the odds of sepsis and chronic renal insufficiency.

Patients with long-standing type 2 diabetes can develop absolute insulin deficiency

S.V. Hope[1,2], M. Shepherd[2], B.M. Shields[2], T. McDonald[2,3], B.A. Knight[2], A.T. Hattersley[2];
[1]Geriatrics, Royal Devon & Exeter NHS Foundation Trust, [2]Peninsula NIHR Clinical Research Facility, [3]Clinical Biochemistry, Royal Devon & Exeter NHS Foundation Trust, Exeter, United Kingdom.

Background and aims: Insulin treatment is increasing in Type 2 diabetes, reflecting the aim for tight glycaemic control, progressive beta-cell failure, and prolonged life expectancy. It is unclear whether the progressive beta-cell failure found in T2D can result in absolute insulin deficiency, with the resulting risk of increased fluctuations in glucose, including severe hypoglycaemia and diabetic ketoacidosis. This may need different treatment from the majority of patients with T2D who have endogenous insulin production. Recent work has developed Urinary C-Peptide Creatinine Ratio (UCPCR) as a non-invasive, stable measure of endogenous insulin production utilising a single urine sample. This has been shown to correlate well with the gold-standard Mixed Meal Tolerance Test in insulin-treated patients. We aimed to assess if absolute insulin deficiency, measured by UCPCR, occurs in T2D.
Materials and methods: We studied 171 insulin-treated subjects who clinically met criteria for type 2 diabetes (diagnosed ≥ 45 years (median age 73, IQR 67-78), and who started insulin ≥12 months post-diagnosis). They provided a spot 2hr post-prandial urine sample, on which UCPCR was measured. Absolute insulin deficiency is defined by UCPCR ≤0.2nmol/mmol.
Results: 23/171 (13.5%) had absolute insulin deficiency (UCPCR≤0.2). Duration of diabetes was significantly longer in those with insulin deficiency (18vs12yrs, p=0.02), and insulin dose in units/kg/24hrs was higher (0.77vs0.5, p=0.01). There was no difference between those with insulin deficiency versus those with endogenous insulin production (UCPCR>0.2) for age of diagnosis (median 58vs58yrs, p= 0.27), BMI (29vs29, p=0.87), HbA1c (8vs7.8, p=0.76), time to insulin from diagnosis (6vs5.5yrs, p=0.31), or number taking oral hypoglycaemic agents (OHA) (12/23 vs 92/148, p=0.36). Of those with absolute insulin deficiency, only 4/23 (17%) were on a basal bolus treatment regime, and 8/23 (34.8%) were on long-acting insulin alone.
Conclusion: UCPCR suggested 13.5% of elderly diabetic patients who met clinical criteria for type 2 diabetes had absolute insulin deficiency. Those who were insulin deficient had had a diagnosis of diabetes for significantly longer than those who retained endogenous insulin secretion, and were on higher doses of insulin. The insulin treatment regimes in the majority of these patients suggested insulin deficiency had not been recognised. Identifying insulin deficiency in long-standing patients with diabetes is important as their management will differ, and UCPCR may have a valuable role in detecting these patients.

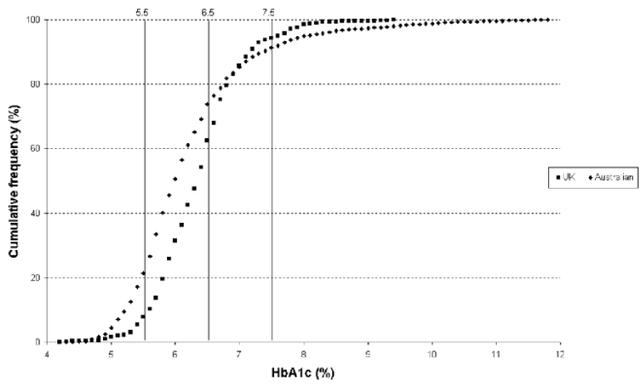
PS 93 Tools for diagnosing and monitoring of diabetes

996

How should HbA_{1c} be incorporated into the diagnostic pathway for diabetes mellitus?

S.E. Manley[1], P.G. Nightingale[2], K.A. Sikaris[3], I.M. Stratton[4], R. Cramb[1], S.C.L. Gough[5];
[1]Clinical Biochemistry, University Hospital Birmingham NHS Foundation Trust, United Kingdom, [2]Wellcome Trust Clinical Research Facility, University Hospital Birmingham NHS Foundation Trust, United Kingdom, [3]Melbourne Pathology, Australia, [4]English National Screening Programme for Diabetic Retinopathy, Gloucestershire Hospitals NHS Foundation Trust, Cheltenham, United Kingdom, [5]Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom.

Background and aims: Alternative strategies have been suggested for using HbA_{1c} to diagnose diabetes mellitus. An HbA_{1c} cut-point of ≥6.5% has been included by the American Diabetes Association (ADA) in their guidelines for 2010. Other approaches involve limits for HbA_{1c} to 'rule diabetes out/in' and a combination of HbA_{1c} and glucose to reduce oral glucose tolerance testing (OGTT). These strategies are examined in patients referred for OGTT in the UK with impaired fasting glucose (IFG) and patients at risk of diabetes in Australia, 26% with IFG at OGTT.
Materials and methods: OGTT were performed in 500 UK patients by capillary sampling with HbA_{1c} measured by Tosoh G7 & G8 IE HPLC (ion exchange high performance liquid chromatography) analysers and in 1175 Australian patients using venous samples with HbA_{1c} from Bio-Rad Variant II Turbo analysers.
Results: The prevalence of diabetes by WHO criteria was 49% in UK patients, age, median IQ range, 62(53-72) years/52% male, and 35% for Australian patients, age 59(49-68) years/54% male. Those identified with diabetes by WHO in UK cohort were aged 62(53-73) years/52% male and by ADA 64(54-73) years/50% male, p = 0.12 for age & p = 0.54 for gender, and for Australian patients, 61(51-71) years/55% and 59(50-70) years/57%, p = 0.004 & p = 0.056. When limits of <5.5% HbA_{1c} (***N*HbA$_{1c}$** *not diabetic*) and ≥7.5% (***D*HbA$_{1c}$** *diabetic*) are applied to 'rule out/in diabetes', 12% (6%/6% respectively) of UK and 27% (17%/10%) of Australian patients would be identified. Those with ***N*HbA$_{1c}$** in the UK cohort were aged 56(46-65) years/63% male, ***I*HbA$_{1c}$** (*intermediate* 5.5% to 7.4%) 62(53-72) years/51% male and ***D*HbA$_{1c}$** 68(53-74) years/52% male, p=0.26 for age and p=0.42 for gender. For Australian patients, values were 50(39-60) years/53%, 60(52-69) years/54% and 55(47-69) years/57%, p <0.001 & p=0.48. An algorithm combining FPG <7.0mmol/l and HbA_{1c} <6.0% could provide additional benefit by reducing OGTT further as 20% of UK and 28% of Australian patients had HbA_{1c} between 5.5% and 5.9%.
Conclusion: Further studies are required to establish the sensitivity and specificity of HbA_{1c} limits in other populations. The means of referral, age and ethnicity of populations and analyser used for HbA_{1c} may influence limits chosen. In addition, use of a surrogate marker for diagnosis of diabetes will require careful assessment in individual patients of conditions, either clinical or iatrogenic, which could affect haemoglobin or its turnover.



997

Diagnosis of diabetes applying the new and old ADA guidelines - characterisation of patients who do not hit both criteria

L. Bäz, E. Beluchin, N. Müller, T. Heller, C. Kloos, W. Hunger-Battefeld, G. Wolf, U.A. Müller;
Endocrinology, University Hospital Jena, Germany.

Background and aims: For the diagnosis of diabetes the new ADA guidelines for the diagnosis of diabetes recommended the use of the HbA1c test to diagnose diabetes, with a threshold of >=6.5%. Moreover the common criteria for the diagnosis of diabetes, FPG >=7.0mmol/l and 2-h PG >=11,1mmol/l, stay valid. Not in every case the new and the old criterion lead to a diagnosis at the same time. There are patients whose glycaemic status is categorized differently either by the HbA1c or the 2 hour post challenge plasma glucose. These patients have to get characterized, to identify, which criteria is better to use in this situation.
Patients and methods: Data of 729 Patients who had 864 oral glucose tolerance tests and an HbA1c test in proximity of time were analyzed. Patients characteristics: age 40.3 y; HbA1c according to oGTT 5.5%; BMI 29.2 kg/m². HbA1c was DCCT adjusted. The conformity of diabetes-diagnosis of diabetes following the different criteria and potential reasons for non conformance were checked in the digital patient record EMIL.
Results: 28 (3.8%) of 729 patients hit both criteria for the diagnosis of diabetes (HbA1c >=6.5% and 2-h PG >=11.1 mmol/l). 641 patients (87.9%) met none of both criteria and 22 patients (3.0%) met the HbA1c (>=6.5%)- but not the glucose criterion (2-h PG >11.1mmol/l). Lots of these patients, hitting only the HbA1c criteria, had an IFG (n=16), or an IGT (n=16) or both (n=14). Four of these 22 patients had whether IFG nor IGT. In 12 patients (1.6% of all patients) with a follow up the diagnosis could be confirmed by abnormal 2h-PG at a later time. In 4 patients HbA1c dropped below 6.5%, stayed or increased and 6 patients had no or only short follow up. 5.2% (n=38) of all patients had abnormal 2-h PG (>=11.1 mmol/l) at diagnosis but HbA1c below the limit (<6.5%). In 15 patients (2.1% of all patients) with follow up HbA1c rose above 6.5% and they met both criteria for diagnosis of diabetes. Nine patients with follow up (1.9%) stayed below an HbA1c 6.5%. Fourteen 14 patients (1.9%) had no or only short follow up to show changes in HbA1c. Confounder which could interfere with Hba1c were rare (severe illness 3, anaemia 2, hypoglycaemic agents 0, corticoids 0).
Conclusion: Applying the new ADA criteria for diabetes diagnose to an caucasian population we found concordance between HbA1c criterion and 2h post challenge criterion in in 91.7% of the all patients and an additional 3.7% within 12 month after the first test. Thus, HbA1c is a suitable parameter for diagnosis of diabetes mellitus.

Conformity of HbA1c and 2h post challange plasma glucose for diagnosis of diabetes

	2-h PG <11,1mmol/l	2-h PG >=11,1mmol/l
Hba1c < 6.5%	641 patients (87.9%)	38 patients (5.2%)
Hba1c >= 6.5%	22 patients 3.0%)	28 patients (3.8%)

998

Detecting undiagnosed diabetes using HbA_{1c}, an automated screening test in hospitalised patients

N.A. Valentine[1], T.M. Alhawassi[2], G.W. Roberts[3], P.P. Vora[4], S.N. Stranks[4], M.P. Doogue[1];
[1]Discipline of Pharmacology, Flinders University, Bedford Park, Australia, [2]College of Pharmacy, King Saud University, Saudi Arabia, [3]Pharmacy Department, Repatriation General Hospital, Daw Park, Australia, [4]Southern Adelaide Diabetes and Endocrine Services, Bedford Park, Australia.

Background and aims: Diabetes is associated with morbidity, mortality and use of health care resources. The prevalence of diabetes in hospitalised patients is approximately three times community prevalence. HbA1c has been recently recommended as a diagnostic tool for diabetes. The aims of this study were to assess the utility of A1C as an automated screening test for undiagnosed diabetes in hospitalised patients and to estimate the prevalence of undiagnosed diabetes in hospitalised patients.
Materials and methods: A 3 month prospective observational study of all adult patients admitted to a tertiary hospital. An A1C test was automatically undertaken on admission for all patients with random plasma glucose (RPG)

≥5.5mmol/L. Demographic, admission and biochemical data were obtained from hospital databases. A subset of patients were recruited for an oral glucose tolerance test (OGTT) post discharge. Undiagnosed diabetes was defined as A1C ≥6.5% in accordance with International Expert Committee and American Diabetes Association recommendations.

Results: The prevalence of undiagnosed diabetes was 11% (95%CI 9.8-12.4) (262/2360) during the 3 month study (figure 1). A further 312 patients with known diabetes were admitted. The prevalence of undiagnosed diabetes was highest in the 65-74 age group. In this study, the A1C test cost was US$152 per new diagnosis of diabetes. Conservatively assuming an annual incidence of undiagnosed diabetes of 0.8% the ongoing cost of testing hospitalised patients using A1C would be US$1,900 per new diagnosis of diabetes. RPG was not sensitive or specific in diagnosing diabetes. Patients were poorly compliant with OGTT, with a 27% completion rate.

Conclusion: Undiagnosed diabetes is common in hospitalised patients. A1C is a simple, inexpensive screening test that can be automated using existing clinical blood samples. Hospital screening for diabetes needs to be coupled with resources for follow up and management in the community.

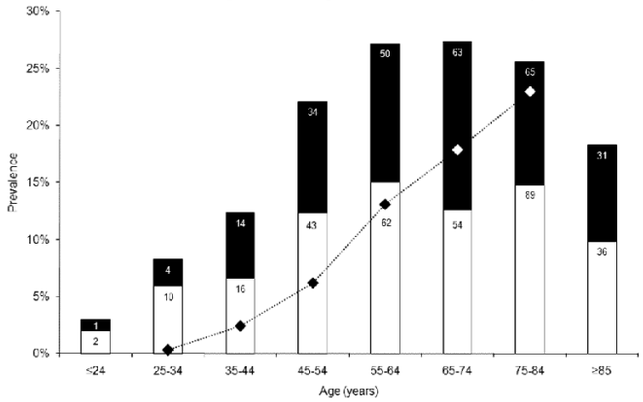


Figure 1: Prevalence (%) of diabetes in hospitalised patients according to age. The number in each group is shown within the columns. White bars indicate patients with previously known diabetes, black bars indicate patients with undiagnosed diabetes. Diamonds indicate the Australian community population prevalence.

999

Challenging the "Monnier Concept": High basal (not postprandial) glucose dominates hyperglycaemic exposure over a wide range of HbA_{1c} on oral therapy and contributes significantly even after addition of basal insulin

M. Riddle[1], G.E. Umpierrez[2], A. DiGenio[3], R. Zhou[4], J. Rosenstock[5];
[1]Oregon Health & Science University, Portland, [2]Emory University, Atlanta, [3]sanofi-aventis, Bridgewater, [4]Medpace, Cincinnati, [5]Dallas Diabetes & Endocrine Center, USA.

Background and aims: Monnier et al reported that there was more contribution to overall hyperglycemia by postprandial hyperglycemia (PPHG) and less from basal hyperglycemia (BHG) at lower vs higher glycated hemoglobin A1C (A1C) levels. That analysis of 4-point profiles, from 290 patients treated with diet ± oral agents without insulin, is often interpreted as supporting the treatment of PPHG rather than BHG, unless the A1C is quite high. The current analysis was designed to study these effects of basal insulin in a larger population with more detailed glucose profiles.

Materials and methods: We evaluated data from a large population of patients with type 2 diabetes and 7-point self-measured plasma-referenced glucose profiles pooled from 6 studies in which basal insulin alone (insulin glargine or NPH insulin) was added to diet ± oral agents and was systematically titrated.

Results: 1699 participants (aged 59 ± 9 y, type 2 diabetes duration 9 ± 6 y) had baseline laboratory-measured fasting plasma glucose (FPG) of 10.7 ± 2.7 mmol/L and A1C of 8.7% ± 0.9%. After 24 to 28 weeks of insulin treatment, FPG was 6.94 ± 2.1 mmol/L, A1C was 7.0% ± 0.9%, and symptomatic hypoglycemia occurred in 60.9% of patients. We computed the contributions of BHG and PPHG to total hyperglycemic exposure above 5.55 mmol/L. Results for ranges of A1C at baseline and after treatment are shown below.

	Baseline					On Basal Insulin				
	<8.0	8.0-8.4	8.5-8.9	9.0-9.4	≥9.5	<6.5	6.5-6.9	7.0-7.4	7.5-7.9	≥8.0
N	422	348	298	245	386	437	449	351	237	225
A1C, %	7.6	8.2	8.7	9.2	10.0	6.0	6.7	7.2	7.7	8.7
BHG, %	76	78	79	79	80	42	41	42	43	48
PPHG, %	24	22	21	21	20	58	59	58	57	52

A1C correlated weakly with hyperglycemic exposure from BHG vs PPHG at baseline (P=0.074) and more significantly after improvements on basal insulin (P=0.0155). Insulin therapy reduced the basal contribution from 76%-80% to 41%-48%.

Conclusion: 1) When oral therapy is unsuccessful, BHG dominates hyperglycemic exposure over a wide range of A1C. 2) Adding basal insulin reduces basal hyperglycemic exposure and A1C, increasing the relative contribution of PPG, independent of A1C ranges. 3) BHG contributes >40% to hyperglycemic exposure, and A1C may be lowered further with basal insulin even when A1C approaches 7.0%.

1, 5-Anhydroglucitol as a marker of short term glucose variability in well-controlled type 2 diabetes mellitus

Y.J. Lee[1], K.S. Suh[2], M.C. Choi[1], Y.C. Hwang[1], S. Chon[3], I.-K. Jeong[3], S. Oh[3], K.J. Ahn[3], H.Y. Chung[3], J.-T. Woo[3], S.-W. Kim[3], J.-W. Kim[3], Y.K. Choi[4], Y.S. Kim[3];
[1]Department of Endocrinology and Metabolism, Kyung Hee University Hospital, Seoul, [2]Department of Endocrinology and Metabolism, Hyundae Hospital, Namyangju Si, Gyeonggi-Do, [3]Department of Endocrinology and Metabolism, Pochon CHA University, Seoul, Republic of Korea.

Background and aims: 1, 5-Anhydroglucitol (AG) is a glucose analogue present in the blood and its levels decrease when there is glycosuric hyperglycemia. The usefulness of 1, 5-AG in reflecting glycemic excursions have been demonstrated in moderately controlled patients to some extent, although some studies reveal controversial results. However, even patients with well-controlled diabetes, demonstrated by HbA1C<7%, may be subject to glycemic excursions and postprandial hyperglycemia. The aim of this study was to evaluate the role of 1,5-AG in patients with well-controlled type 2 diabetes in monitoring short term glycemic control and glucose variability, as assessed by the continuous glucose monitoring system (CGMS), when compared to fructosamine (FA).

Materials and methods: 33 patients with type 2 diabetes with HbA1C <7% with stable glycemic control were recruited. CGMS was applied to the patients for two consecutive 72-h periods. A standardized and objective approach to measure glycemic variability by CGMS_the absolute group of signs (GOS) method, which has a high correlation with the mean amplitude of glucose excursion (MAGE), was calculated. This, along with the mean postmeal maximum glucose (MPMG) and area under the curve for glucose above 180 mg/dL (AUC180), which all reflect the daily glycemic status, were compared with 1,5-AG and FA at baseline, day 4, and day 7.

Results: Baseline characteristics of the enrolled subjects were as follows: age, 56 ± 9.6 yrs; BMI, 25.5 ± 3.6 kg/m^2; DM duration, 4.9±5.0 yrs; HbA1C, 6.3±0.3%; basal 1,5-AG, 15.8±7.6 ug/mL; basal fructosamine, 276.1±23.5 umol/L. Mean 1,5-AG levels were negatively correlated with MPMG (r = -0.287, p < 0.05), AUC180 (r = -0.264, p < 0.05) and absolute GOS (r = -0.253, p < 0.05), whereas FA levels were correlated positively with fasting plasma glucose (r = 0.519, p < 0.01), MPMG (r = 0.498, p< 0.01), AUC180 (r = 0.52, p < 0.01), and absolute GOS (r = 0.285, p < 0.05). When 1,5-AG levels were divided into two groups using 14ug/mL as the cut-off value for well controlled DM, there was a statistically significant difference: 1,5-AG<14ug/mL group, compared to the 1,5-AG>14ug/mL group, had higher fasting plasma glucose (120.84±15.46mg/dL vs 109.24±11.13mg/dL, p=.002), MPMG (201.84±34.75mg/dL vs 173.13±24.41mg/dL, p=.001), AUC180 (5.10±5.49 mg/dL/day vs 1.56±2.27mg/dL/day, p=.003), and absolute GOS values (67.05±25.62 mg/dL vs 54.54 ±20.52mg/dL , p=.035), meaning greater glycemic variability.

Conclusion: 1, 5-AG reflects glycemic variability and postprandial hyperglycemia even in well-controlled DM patients, which suggests the usefulness of this as a complementary marker along with fructosamine.

Defining the phenotype of the fast and slow deglycators by analysis of the glycation gap

B.M. Singh, A.U. Nayak;
Wolverhampton Diabetes Centre, United Kingdom.

Background and aims: Despite the reliability of the Haemoglobin A_{1c} (HbA_{1c}) assays discordance between HbA_{1c} and other measures of glycaemia is often encountered. It is now recognised that there are enzyme dependent processes in the red blood cells that cause deglycation and thus influence the HbA_{1c} independent of the prevailing glycaemia. Thus the HbA_{1c} is the net of the glycation and deglycation. The rates of intracellular deglycation may vary between individuals. Fructosamine is the glycation of albumin which is extracellular and so is not affected by the intracellular deglycating enzymes. Co-analysis of HbA_{1c} and Fructosamine pairs, utilising the Fructosamine to determine a predicted HbA_{1c}, can define the 'glycation gap' (G-gap). Our objective is to determine if the glycation gap in any individual is consistent over time.
Materials and methods: We analysed all HbA_{1c} estimations (n=111205) done over a 4 year period at New Cross Hospital. 4724 people had simultaneous HbA_{1c}-Fructosamine estimations. 2263 people had at least two paired HbA_{1c}-Fructosamine estimations separated by 10±8 months. The G-gap was calculated as the HbA_{1c} minus the standardised Fructosamine derived HbA_{1c} equivalent ($FHbA_{1c}$). A negative G-gap may denote a fast deglycation state with the HbA_{1c} appearing to read lower than predicted, and a positive G-gap denotes a slow deglycation state. To ascertain the consistency of the G-gap, the G-gap for the 2nd HbA_{1c}-Fructosamine pair was calculated expecting a consistency of distribution of negative through positive values. If so, the multiple of G-gap1 and G-gap2 (whether negative or positive) will always be positive if consistent but negative with any discordance.
Results: Of the 2263 people with at least two paired HbA_{1c}-Fructosamine, their characteristics were age 60±14 years, males 55%, HbA_{1c} 8.3±1.7 (4.0-17.7) % (mean±SD (range)) and Fructosamine 308±77 (143-978) µmol/l. The $FHbA_{1c}$ was 8.3±1.7 (4.6 - 23.4) % and the HbA_{1c} minus $FHbA_{1c}$ was 0.0±1.2 (-8.2 to +5.9). Setting G-gap cut offs at <= -1, >-1 to <+1, and >= +1 as Fast, Neutral and Slow deglycators the cohort's distribution was 421 (19%), 1448 (64%) and 394 (17%) respectively. The G-gap multiple (multiple of G-gap1 and G-gap2) was 1.2±2.6 (-6.1 to +40.9). The G-gap consistency was 97% in 421 Fast deglycators (G-gap <= -1) and 99% in 394 Slow deglycators (G-gap >= +1).
Conclusion: The G-gap is consistent over time, thus by inference an individual's rates of deglycation appear to be consistent and thus this may be a method of defining the phenotypic expression of underlying metabolic and genetic processes.

Background and aims: Age-related decline of muscle strength is closely related with a loss of muscle mass and an increase in fat, which are the important features in insulin-resistant states. However, very little data are available on the association of muscle strength with diabetic complications in patients with type 2 diabetes. The aim of this study was to investigate whether grip strength is associated with glycemic control and status of diabetic complication in patients with type 2 diabetes.
Materials and methods: This was an observational study performed in 193 type 2 diabetic patients with duration of diabetes within 3 years and age- and sex-matched 40 healthy individuals. Grip strength was measured by isometric dynamometry. Thigh circumference was measured for each subject. Diabetic complications were ascertained via review of medical records. Chronic kidney disease was defined as estimated glomerular filtration rate < 60 mL/min/1.73 m^2.
Results: Grip strength was correlated with age (r=-0.491, P<0.001), body mass index (r=0.133, P<0.05), and diabetes duration (r=-0.184, P<0.001). Diabetic patients had lower grip strength than healthy individuals. Especially, grip strength of poorly glycemic controlled patients (HbA1c > 7.5%) had lower than that of well controlled patients (HbA1c ≤ 7.5%). And grip strength was lower in diabetic patients with retinopathy, neuropathy, chronic kidney disease, or cardiovascular disease, compared to those without these complications. With the exception of retinopathy, these trends remained significant after adjusting for age, body mass index, waist, diabetes duration, and medications.
Conclusion: Our findings suggest that grip strength is associated with glycemic control and diabetic complications. The potential for grip strength to be used in the clinical practice of diabetic patients needs to be explored.

PS 94 Insulin pumps: a promise of improvement in metabolic control

1003

HbA_{1c} and sensor use in adults during a 1-year randomised controlled trial comparing sensor-augmented pump therapy and multiple daily injection therapy

A. Ahmann[1], J.B. Buse[2], R.M. Berganstal[3], R. Tanenberg[4];
[1]Oregon Health & Science University, Portland, [2]University of North Carolina School of Medicine, Chapel Hill, [3]International Diabetes Center at Park Nicollet, Minneapolis, [4]Diabetes and Obesity Center, Greenville, USA.

Background and aims: Recent studies have shown that continuous glucose monitoring (CGM) can improve glycemic control. The purpose of the STAR 3 study was to evaluate whether CGM combined with insulin pump therapy (sensor augmented pump, SAP) might improve A1C without increasing hypoglycemia.
Materials and methods: STAR 3 was a 1-year multicenter randomized controlled trial comparing SAP therapy to glargine- and aspart-based multiple daily injection (MDI) therapy in 329 adult (age 19-70 years) and 156 pediatric (age 7-18 years) subjects with type 1 diabetes. Preliminary results for the adult cohort of the following outcomes are given for overall A1C, A1C by age group, sensor use, and severe hypoglycemia.
Results: The primary endpoint of change in A1C from baseline to 1 year showed the decline in mean A1C levels was greater with SAP therapy compared to MDI therapy (SAP: from 8.3±0.5% to 7.3±0.7%; MDI: from 8.3±0.5% to 7.9±0.9%; treatment difference -0.6%; 95% CI, -0.77, -0.45; p<0.001). Severe hypoglycemia did not differ between treatment cohorts (p=0.53). There was a decrease in A1C from baseline to 1 year for all SAP adults of -0.9; for those 19-35 years (n=59), the decrease was -0.7; for those 36-50 years (n=58), the decrease was -1.1; and for those 51-70 years (n=49), it was -1.1. Treatment differences between groups in change in A1C significantly favored SAP therapy for all adults (-0.6, p<0.001) and in 2 age cohorts (-0.6 among subjects 19-35 years, p=0.01; -0.8 among subjects 36-50 years, p<0.001; with a favorable downward trend of -0.3 among subjects 51-70 years, p=0.16). Most SAP subjects used the glucose sensor ≥60% of the time (57.6% among subjects 19-35 years of age, 82.8% among subjects 36-50 years of age, and 91.8% among subjects 51-70 years of age). The Figure shows the r value of -.28 between sensor use and change in A1C from baseline to 1 year.
Conclusion: SAP therapy reduces A1C in adults of all ages with type 1 diabetes. Reduction in A1C appears to be related to sensor use, which showed a tendency to increase with age, but was relatively high across all ages.

Improved glucose control with sensor-augmented pump therapy in youth with type 1 diabetes and elevated HbA_{1c} levels on multiple daily injection therapy in the STAR 3 Study

W.V. Tamborlane[1], R. Slover[2], A. Criego[3], M. Daniels[4], C.M. Foster[5], R.C. McEvoy[6], C. Orlowski[7], S. Weinzimer[1], N. White[8], S.M. Willi[9], STAR 3 Study Group;
[1]Pediatrics, Yale School of Medicine, New Haven, [2]Pediatrics, Barbara Davis Center for Childhood Diabetes, Aurora, [3]International Diabetes Center, Minneapolis, [4]CHOC, Orange, [5]University of Utah, Salt Lake City, [6]Children's Hospitals and Clinics of Minnesota, Minneapolis, [7]University of Rochester, Rochester, [8]Washington University, St. Louis, [9]CHOP, Philadelphia, USA.

Background and aims: The effectiveness of continuous glucose monitoring (CGM) in children with type 1 diabetes (T1D) maintained on pre-existing insulin pump or multiple daily injection (MDI) treatment remains unproven. No previous study has examined the effect of initiating both CGM and insulin pump therapy simultaneously in a large pediatric cohort with T1D.
Materials and methods: This 1-year multicenter, randomized controlled trial compared an integrated sensor-augmented pump (SAP) system to MDI therapy in 156 youths with T1D with sub optimal control (A1C =7.4 - 9 .5%). A1C values were measured every 3 months and the primary outcome was the change in A1C from baseline to 12 months in the total cohort. Results were also stratified according to age (82 children, age 7-12 and 74 adolescents, age 13-18) and by the amount of time glucose sensors were worn in the SAP group.
Results: Baseline A1C levels did not differ between the SAP group (8.26±0.55%) and the MDI group (8.30±0.53%). At the end of 12 months, the change in A1C from baseline in the SAP group was -0.39±93% versus +0.16±0.95% in the MDI group, a between-groups difference of -0.49% (95% CI, -0.75 to -0.18; P=.002). The proportion of subjects reaching ISPAD-recommended A1C values (i.e., <7.5%) was 29.5% in the SAP group versus 10.3% in the MDI group (P=0.0075). As shown in the Figure, the change in A1C at 12 months in 7-12 yr old subjects favored the SAP group by -0.44% (95% CI, -0.80 to -0.07; P=0.02 vs MDI subjects) and by -0.62% (95% CI, -1.09 to -0.15, P= 0.01) in 13-18 year olds. In the entire SAP cohort, greater decrements in A1C were associated with increasing sensor wear (r=-0.30, P=0.008). Rates of severe hypoglycemia (<10 events/100 pt yrs) and DKA were low and did not differ between the two treatment groups.
Conclusion: SAP is an effective means of improving metabolic control and in achieving target A1C levels without increasing the frequency of acute complications in youth with T1D who have elevated A1C levels on MDI therapy. Increasing sensor use tends to improve the effectiveness of the SAP system.

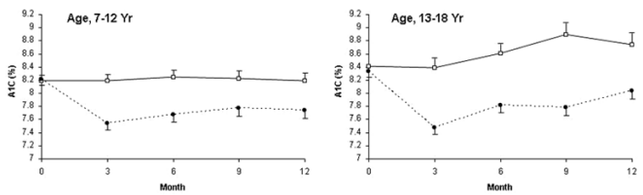

Figure. Quarterly mean (±SEM) A1C levels in pediatric and adolescent subjects. *Open squares*, MDI treatment arm; *filled circles*; SAP treatment arm.

Long term outcomes of intensive treatment with subcutaneous insulin infusion (CSII) in patients with type 1 diabetes mellitus

I. Gonzalez-Molero[1], M.E. Domínguez-López[1], E. Rubio[1], M. Carreira[2], S. Gonzalez-Romero[1], M.S. Ruiz de Adana-Navas[1], F. Soriguer-Escofet[1];
[1]Endocrinology, [2]Psichology, Carlos Haya Hospital, Malaga, Spain.

Introduction: Several studies have shown that treatment with insulin pump is an effective therapy for selected type1diabetes. Nevertheless, most of them analyse results in short period of time. The objective of this study is to evaluate long term effects on quality of life (DQOL) and metabolic control of CSII.
Material and methods: We did a longitudinal study of type 1 diabetic patients previously treated with multiple daily insulin (MDI) therapy who initiated insulin pump and maintained it for longer than three years. Initially we recruited 105 patients and after we excluded pregnant and patients using

combined sensor-pump systems. Finally we analysed in 69 patients: diabetes duration, complications, cause of initiating CSII, total daily insulin requirements, hypoglycaemias, Hba1c, DQOL, physical evaluation, number of controls and number of medical visits.
Results: The criteria for csii initiation were: 21,9% hypoglycaemic events, 37,5% poor metabolic control and 40,6% glycemic lability. After three years, 79,64% continue using insulin pump, 12,2% dropped out and 8,16% withdrawn following medical reasons.

*P<0,05	Basal	6 month	12 month	24 month	36 month
HbA1c	8.11±2,2	7.6±1,3*	7,8±0.9*	7,2±2,6*	8,2 ±0.97
Severe Hypoglycemic events/year	0,43	0,06	0	0	0,03
Hypoglycemic events/ week	4,5±3	3,3±2,8	2,1±1,7*	2,8±2,2*	2,7±1,6

[Long term evaluation of CSII]

Conclusions: CSII achieve a good metabolic control during the first two years and an improvement in DQOL that is maintained during all the evaluated period of time.

1006

Insulin requirements, basal-bolus distribution and basal patterns used by type 1 diabetic patients (T1DM) starting insulin pump therapy (CSII) and after glucose control optimisation

I. Saigi[1], D. Tundidor[1], L. Jordana[1], M.A. María[1], R. Corcoy[2], A. Chico[2];
[1]Endocrinology, [2]Endocrinology, Eduab-HSP, Hospital Sant Pau, Barcelona, Spain.

Introduction: Insulin requirements of insulin at the beginning of CSII therapy is usually calculated from total daily doses (TDD) used with multiple daily injections (MDI). Basal-bolus distribution of 50%-50% with only one basal rate per day is the usual pattern at that time. However, there are only few evidences about the best form to start CSII in MDI treated patients.
Aim: The aim of the study was to assess insulin requirements, basal-bolus distribution and basal rate pattern used by a group of T1DM subjects using CSII after glucose optimization.
Patients and methods: 50 T1DM patients who started CSII therapy at 2008 were included (10 males, 40 women; 39.6±11 years; diabetes duration 19.9±11 years; HbA1c 7.9±0.9%). Indications: suboptimal glucose control (n=31) and pre-gestational optimization (n=19). TDD was calculated reducing around 20% the previous TDD in MDI regimen. TDD was divided into 50% basal (proportionally distributed along the 24 hours) and 50% pre-meal boluses (distributed according to carbohydrates at each meal). Doses and pattern distribution were modified according to glucose profile during the follow-up (1, 2 and 3-5 months after CSII initiation). After glucose profile optimization (4-6 months), TDD, basal-bolus distribution and number of basal rates were recorded and HbA1c was measured.
Results: In comparison to TDD in MDI, TDD at the beginning of CSII was reduced by 18.3%. At the end of the study the reduction of TDD was only 15.8% (non-significant). Basal rate was initially reduced by 17% and at the end by 8.6% ($p<0.05$). Basal rate represented 52.3 ± 11% of TDD at the beginning, however at the end of the study represented 58.5 ± 18% ($p<0.05$). Women needed more proportion of basal rate than males (60.6 ± 18 vs. 49.1 ± 13%; $p<0.05$), and those patients with diabetes duration >15 years, compared to those with <15 years of duration (61.8 ± 20 vs. 51.9 ± 12; $p<0.05$). Final number of basal rates/day were 5 ± 3 and this number was higher in patients with HbA1c<6.5% compared to those with HbA1c >6.5% at the end of the study (7.8 ± 4 vs. 4.1 ± 2; $p<0.05$). Basal rate infusion range was 0.81-1.01 units/hour (maximum 5-8 h AM, minimum 9-12 h AM). No differences were found between reduction in boluses at the beginning or at the end of the study for each meal. The distribution of the doses dedicated to boluses was 37% for lunch, 33% for dinner and 30% for breakfast). HbA1c levels decreased significantly 4-6 months after CSII initiation (HbA1c 7.1±0.9%; $p <0.05$).
Conclusion: In our T1DM patients starting CSII, the reduction of TDD from TDD used in MDI should be around 15%. Basal rate should be >50% of TDD especially in women and patients with longer diabetes duration (around 60%). Basal profile should be divided in > 3 patterns/day, because higher number of basal rates/day was related with better glucose control. HbA1c decreased by 0.8% 4-6 months after CSII initiation.

Good metabolic control with a continuous subcutaneous insulin infusion (CSII) in type 2 diabetic patients uncontrolled by insulin optimisation

J.-P. Donnet[1], J.-P. Courrèges[2], S. Clavel[3], T. Gabreau[4], D. Gouet[5], E. Verlet[6], E. Cosson[7], P. Jan[8], B. Cirette[9], E. Leutenegger[10];
[1]University Hospital Centre, Pointe à Pitre-Guadeloupe, [2]Hospital Centre, Narbonne, [3]Hospital Centre, Le Creusot, [4]Hospital Centre, Auxerre, [5]Hospital Centre, La Rochelle, [6]Hospital Centre, Dunkerque, [7]Hospital Centre, Bondy, [8]Hospital Centre, Bar le Duc, [9]Dinno Santé, Marne la Vallée, [10]ABR Pharma, Paris, France.

Background and aims: Metabolic control in type 2 diabetic patients (T2D) treated with a continuous subcutaneous insulin infusion (CSII) is a real challenge. Moreover, it is a real great difficulty to reach in T2D the classic targets of GMC defined by normalization of Hba1c associated with no weight increasing and no severe hypoglycemia, so what is the efficacy of ambulatory insulin pump in this T2D population?
Materials and methods: A longitudinal observational study is performed since 2009, involving 28 French hospital centres in order to described circumstances of insulin pump initiation and patient management over 3 years. We have selected a population of T2D patients with a poor metabolic control despite optimization of insulin treatment (3 or 4 injections/day).
Results: To date, 161 patients have been included in the study. Follow-up data are available for 60 patients. 5 patients have stopped CSII (patient's wish - n=3, psychological reasons - n=2), and 55 patients were followed since one year: mean age 58±10 years old, 49% male and mean BMI 34±6 kg/m². 27 patients (54%) have lost at least 10% of HbA1c since their inclusion and 19 patients didn't gain over 2 kg per point of HbA1c losing between inclusion and 1 year follow-up. A Good Metabolic Control (GMC) group has been defined *a posteriori* with the following criteria: patient with no hypoglycaemia reported since inclusion who didn't gain over 2 kg per point of HbA1c losing between inclusion and 1 year follow-up and who have lost at least 10% of HbA1c since their inclusion. According to those criteria, 16 patients (30%) in our cohort are in GMC. Despite the low number of patients, comparisons on principal criteria are presented in the table below: significant differences have been logically observed on weight and HbA1c criteria. A significant higher level of HbA1c at inclusion seems to be a predictive factor for targeting GMC criteria at 1 year follow-up (p=0.07).

Comparisons on principal criteria : GMC group versus Others group

	**responding patients*	GMC group	Others group	*Test value*
Age (years)	T0	62±6	57±11	ns
Sex (% women/ % men)	T0	56/44	49/51	ns
Weight (kg)	T0	92±16	96±20	ns
	T12	93±17	99±21	ns
	Δ* T0/T12	+0.37±3.08	+4.36±5.9	0.005
IMC (kg/m²)	T0	33.15±3.77	34.41±6.50	ns
	T12	33.72±3.83	35.51±6.49	ns
	Δ* T0/T12	+0.23±1.27	+1.47±3.84	ns
HbA1c (%)	T0	9,99±2,34	8,78±1,51	0.07
	T12	7.75±1.52	8.04±1.37	ns
	Δ* T0/T12	-2.24±1.65	-0.62±1.58	0.0004
Severe hypoglycaemia (%)	Before T0	6	5	ns
	Since T0	0	0	ns
CSII associated with metformin (%)	T0	63	41	ns
Insulin dose (unit/kg/ day)	T0	0.76±0.3	0.83±0.32	ns
	Δ* Before T0/T0	-0.35±0.55	-0.23±0.37	ns
	Δ* Before T0/T12	-0.34±0.49	-0.10±0.43	ns

Conclusion: After 1 year of CSII, half of our patients obtain a good glucose control, and a third reach the targets of good metabolic control. These preliminary data emphasize the benefit of this treatment for T2D patients with poor metabolic control despite basal bolus optimization. At this stage, it is

difficult to show predictive factors of targeting GMC criteria, but further data on the global cohort could be conclusive.

Insulin pump therapy safely improved glycaemic control and patient reported outcomes in patients with type 2 diabetes suboptimally controlled with multiple daily injections

J.P. Frias[1], S.V. Edelman[2], B.W. Bode[3], T.S. Bailey[4], M.S. Kipnes[5], R.L. Brunelle[6], X. Chen[1];
[1]Clinical Affairs, LifeScan, Inc., Milpitas, [2]Department of Endocrinology and Metabolism, VA San Diego Healthcare Center, [3]Atlanta Diabetes Association, [4]AMCR Institute, Inc., Escondido, [5]Cetero Research, San Antonio, [6]Bowsher Brunelle Smith LLC, Carmel, USA.

Background and aims: Insulin pump therapy is an important treatment option for patients with type 2 diabetes (T2DM) who are suboptimally controlled with multiple daily injections (MDI). Limited data exist about pump therapy in this patient population. The objective of the present sub-analysis of a larger study was to assess the efficacy, safety and patient reported outcomes (PRO) of 16 wks of pump therapy in patients with T2DM suboptimally controlled with MDI therapy.
Materials and methods: In this 16-wk, open-label, multicenter study, 21 insulin pump naïve patients treated with MDI ± oral antidiabetic agents (9 male, 12 female, anti-GAD antibody negative, age 57±13, DM duration 15±6y, A1C 8.4±1.0%, FPG 9.2±3.2mmol/l, body weight 98±20kg, BMI 34±5kg/m^2, total daily insulin dose 99±65U [1.0U/kg], mean±SD) discontinued all diabetes medications except metformin and initiated insulin pump therapy (Animas® 2020 insulin pump with insulin glulisine) with one daily basal rate and bolus doses at each meal. Insulin doses were titrated to safely achieve the best possible glycemic control. The primary outcome was assessment of insulin dose and insulin dosing patterns at Wk 16. Secondary outcomes included change in A1C, fasting and postprandial glucose, body weight, PRO (Insulin Delivery System Rating Questionnaire), and hypoglycemia.
Results: Glycemic control improved significantly after 16 wks of pump therapy: A1C 7.3±1.0% (-1.1±1.2%, p<0.001) and FPG 7.2±2.1mmol/l (-2.0±4.1mmol/l, p<0.001). In patients with baseline A1C >8.5% (n=11, mean baseline A1C 9.1±0.5%), A1C was reduced by 1.9±1.3% (p<0.005). Mild hypoglycemia was experienced by 81% of patients at least once during the 16-wk study with no episodes of severe hypoglycemia. At Wk 16, the mean daily basal, bolus, and total insulin doses were 66±36U, 56±40U, and 122±72U (1.2U/kg), respectively. 90% of patients were treated with ≤2 basal rates per day (1 basal rate 80%; 2 basal rates 10%). Body weight increased by 2.7±2.6kg (p<0.001). PRO measures improved significantly from baseline (Treatment satisfaction: 65±15 vs 81±15, p<0.001; Overall treatment preference: 58±14 vs 93±16, p<0.001; Scale of 0-100, Mean±SD).
Conclusion: Insulin pump therapy using a simple dosing regimen significantly improved glycemic control in patients with T2DM who were suboptimally controlled with MDI therapy. Patients experienced moderate weight gain, no severe hypoglycemia and preferred pump therapy to baseline treatment with insulin injections. Efforts to develop simple, cost-effective insulin pumps for patients with T2DM must continue. Future controlled trials are needed to further assess the benefits of insulin pump therapy in T2DM.

A head-to-head-to-head comparison of three bolus calculators in subjects with type 1 diabetes

H.C. Zisser[1], R. Wagner[2], S. Pleus[3], C. Haug[3], N. Jendrike[3], C. Parkin[4], G. Freckmann[3];
[1]Clinical Research, Sansum Diabetes Research Institute, Santa Barbara, USA, [2]Global Medical Affairs, Roche Diagnostics Operations, Indianapolis, USA, [3]Institute for Diabetes Technology, Ulm, Germany, [4]Health Management Resources, Inc., Carmel, USA.

Background: Insulin pump systems now provide automated bolus calculators (ABCs) that electronically calculate insulin boluses to address carbohydrate (CHO) intake and out-of-range blood glucose (bG) levels. We compared the efficacy of three ABCs (ACCU-CHEK® Combo [Roche IDS] / Animas® 2020 [Animas] / MiniMed Paradigm Bolus Wizard® [MiniMed]) to safely reduce postprandial hyperglycemia (PPH) in type 1 diabetes mellitus (T1DM).
Methods: T1DM subjects (n=24) were recruited at a single center for a prospective, triple cross-over study. ABCs with programmed target range (80-140 mg/dl) were used in random order. PPH was induced by reducing the calculated bolus by 25%. At two hours after test meals, the ABCs were allowed to determine whether a correction bolus was needed. Differences between bG values at six hours after test meals that achieved 2-hour PPH and the mean of the target range (110 mg/dl) were determined.
Results: The mean difference between 6-h bG levels following test meals and the 110 mg/dl bG target with the MiniMed device (47.4 ±31.8 mg/dl) was significantly (P<0.05) higher than the Animas (17.3 ±30.9 mg/dl) and Roche (18.8 ±33.8 mg/dl) devices. The number of meals with 2-hour PPH and the bG levels at 2 hours was similar. Roche and Animas devices recommended correction boluses significantly more frequently than the MiniMed device (P<0.05). Significant hypoglycemia was not associated with ABC use.
Conclusion: In this study, the Roche and Animas devices were more efficacious in controlling PPH than the MiniMed device. Use of ABCs can assist in controlling postprandial glycemia without significant hypoglycemia.

Effects of evening meals with complex nutrient content on the nocturnal blood glucose levels of type 1 diabetes patients

S. Carstensen[1], J.W. Huber[1], M. Schönauer[2], A. Thomas[3];
[1]Life Sciences, Roehampton University, London, United Kingdom, [2]Akademische Lehrpraxis der Universität Leipzig, Germany, [3]Medtronic GmbH, Meerbusch, Germany.

Background and aims: Currently no therapy recommendations are available as to how postprandial blood glucose levels can be improved after meals rich in protein and fat. Recent epidemiological studies reported reduced insulin sensitivity resulting from fat and protein intake. This implies a need for additional insulin in response to fat and protein intake; otherwise glycaemic control will be compromised. The aim of this study was to examine the effectiveness of calculating the insulin dosage required for an evening meal, taking into account the carbohydrate and the fat and protein content, in contrast to the usual concept of pure carbohydrate cover in adults with type 1 (T1) diabetes using insulin pumps. The study focused on pump-treated T1 diabetes patients.
Methods: Postprandial glucose values were examined over 12 hrs by continuous glucose monitoring (CGMS Medtronic), using a cross-over design. Fourteen insulin pump users took part in the study (10 females; age 39 ± 9 years (mean ± SD), diabetes duration 16.4 ± 6.7 years, insulin pump use 7.6 ± 3.3 years, HbA1c 7.3 ± 0.5%, BMI 26.4 ± 1.9 kg/m^2). Patients with comorbidities or diabetes related complications were excluded. Participants received the same test meal (meat, potatoes, salad and vanilla ice-cream) on three successive evenings. The insulin doses were calculated using 5.5 carbohydrate unit (1 carbohydrate unit = 10g carbohydrate) and 5.5 fat protein unit (1 fat protein unit (FPU) = 100kcal fat and protein). The insulin cover for the carbohydrate was a standard bolus (100% fast-acting) and a dual bolus (50% fast, 50% delayed over 8 hrs). As additional cover for fat protein unit the same insulin amount was used as for a carbohydrate unit. The insulin for the carbohydrate was administered immediately before the meal (quick acting) and for

the fat protein unit delayed over 8 hrs (FPU bolus). Compared were the area under the curve (AUC) as a numerical integral from 145 (1 preprandial, 144 postprandial) sensor glucose values, as well as the number of values under (<80 mg/dl), within (80-140 mg/dl) and above (>140 mg/dl) the target area from the sensor glucose values.
Results: The FPU bolus in comparison with the standard bolus led to a significant improvement in the AUC (22.399 ± 5.909 versus 25.419 ± 6.139, p=.02) and highly significant both within (67 ± 51 versus 34 ± 36, p<.01) and above (74 ± 52 vs. 108 ± 40, p=.01) the target area. For carbohydrate only based insulin dosage, no significant difference could be shown between the standard and the dual bolus; this applies to the total area under the curve and all 3 target areas from the sensor glucose values (25.419 ± 6.139 versus 25.292 ± 5.399, under 3 ± 7 versus 1 ± 2; within 34 ± 36 versus 31 ± 26, above target 108 ± 40 versus 108 ± 40; all p-values >.5). Regarding the comparison between FPU bolus and dual bolus, significantly more values lay within (67 ± 51 versus 31 ± 26, p=.04) and significantly fewer values above (74 ± 52 versus 108 ± 40, p=.03). The FPU bolus did not result in a difference for the lower target area (3 ± 6 versus 1 ± 2, p=.62).
Conclusion: The study therefore suggests that the therapy of T1 diabetes patients should consider insulin cover for the fat and protein portion of a meal as well as the carbohydrates, with the aim of optimising postprandial glucose values and glycaemic control. The study should be repeated in a larger group of insulin pump users with T1 diabetes.

Should the amount of fat and protein be taken into consideration to calculate preprandial insulin bolus?
M. Gonzalez-Rodriguez, A. Prieto-Tenreiro, M. Pazos-Couselo, P. Andujar-Plata, R. Villar-Taibo, D. Peteiro-Gonzalez, C. Guillin-Amarelle, F.F. Casanueva-Freijo, J. Garcia-Lopez;
Hospital Universitario de Santiago de Compostela, Spain.

Background and aims: Continuous subcutaneous insulin infusion (CSII) provides the most physiological way of insulin administration as we can program different basal rates and deliver different types of insulin boluses. Traditionally theses boluses are calculated according to the amount of carbohydrate (CH) eaten. However, there are very few data published related to changes in glycemic response according to meal composition(only carbohydrates (CH) or CH with protein and fat). Our aim is to determine whether the presence of protein and fat could involve a different postprandial glycemic response than that obtained with only CH.
Materials and methods: Observational prospective study. 19 type 1 diabetic patients (for at least 2 years) on CSII (for at least 3 months) wore a blind continuous glucose monitoring system sensor (Minilink real time, Medtronic) for three days. They ingested on different days two meals with the same CH content but different fat and protein content. Mean A1c was 7.7% (range 6.5-8.4%) and mean age was 34 years old (range 30-52).Exclusion criteria: celiac disease or any gastrointestinal disease, any diabetes complication and any medication that could modify gastric emptying. Our protocol was next:
- First day: The sensor was inserted and calibrated
- Second day: Patients ate meal 1: 60g of pasta + 50ml of tomato sauce (meal composition: 50g CH, 3.3g of protein and 8.9g of fat)
- Third day: Patients ate meal 2: 60g of pasta + 50ml of tomato sauce + 150g of veal chop + 10ml of olive oil (meal composition: 50g of CH, 28.9g of proteins and 37.4g of fat)
- Fourth day: Sensor was removed

During the monitoring, alcohol intake and exercise were not allowed. They performed one self-monitoring capillary blood glucose per hour and remained in rest for a least 3 hours after each meal. They used the standard single-wave insulin bolus based on each subjects´s CH- to- insulin ratio and CH counting. Once downloaded the CGMS we analysed:
- Mean glucose 60 min pre-meal (Gm)
- Glucose Standard desviation (SD)
- Area under the curve described from the beginning of the meal until the glucose returned to levels pre-meal (AUC)
- Time (minutes) until glucose returned to values pre-meal (Tn)
- Maximum glucose peak (P)
- Time (minutes) to reach the maximum glucose peak (Tp)<br

A p value <0.05 was considered statistically significant.
Results: Patients started both meals with similar glucose levels. There were no statistical differences between both meals in Tn, AUC, P and Tp (Table 1). The greatest glucose peak was reached at 60 min and 79 min with meal 1 and 2 respectively.

Conclusion: The presence of protein and fat did not determine a different glycemic response. Although a delayed postprandial glucose peak was found in meal 2, this did not reach statistical significance. According to our results, there is no need in using a different insulin bolus when we ate an equilibrated amount of CH, fat and protein in a meal.

Table 1. Gm, AUC, Tn, P and Tp with meal 1 and 2

	Meal 1	Meal 2	p value
Mean Gm (mg/dl)	125.5	124	0.8
Mean AUC (mg/dl.min)	28.1	32.3	0.7
Mean Tn (minutes)	104.6	114	0.9
Mean P (mg/dl)	50	58.6	0.7
Mean Tp (minutes)	59.6	79	0.6

The PANORAMA pan-European survey: glycaemic control and treatment patterns in patients with type 2 diabetes

P. de Pablos-Velasco[1], C. Bradley[2], E. Eschwège[3], L.A. Gönder-Frederick[4], K.G. Parhofer[5], H. Vandenberghe[6], D. Simon[7];
[1]Dr Negrin Hospital, Las Palmas University, Spain, [2]Royal Holloway, University of London, United Kingdom, [3]INSERM U-1018, Paris, France, [4]University of Virginia, Health System, USA, [5]Klinikum der Universität, München, Germany, [6]AstraZeneca, Zaventem, Belgium, [7]Hôpital de la Pitié / INSERM U-1018, Paris, France.

Background and aims: The prevalence of type 2 diabetes (T2D) continues to rise across Europe. Despite effective treatments initiated after diet/lifestyle modifications, many patients still do not achieve an HbA_{1c} target of <7%. PANORAMA is a large pan-European cross-sectional survey (NCT00916513) of patients with T2D treated with glucose-lowering therapies, aimed at assessing treatment satisfaction, quality of life and the proportion of patients achieving an HbA_{1c} <7%. This abstract reports recent data from 8 countries on glycaemic control in patients with T2D in relation to treatment patterns.
Materials and methods: Patients with T2D were randomly or consecutively selected from physician practices (mainly in primary care) in 8 countries (Belgium, Germany, Greece, Italy, Netherlands, Spain, Turkey and UK). Eligible patients: aged ≥40 y, with a diagnosis of T2D for >1 y prior to study entry and an available medical record at the clinic of >1 y. All patients received dietary and exercise advice. Most patients were also being treated with either oral hypoglycaemic agents (OHAs) or injectables (insulin and GLP-1 receptor analogues) with or without OHAs. Treatment type was unchanged in the previous 3 months. HbA_{1c} levels were measured using an identical portable diabetes monitoring system (Bayer's A1Cnow®) in each centre.
Results: 5,156 patients were included in the study from June to November 2009: 47.8% women; mean age 65.9 y (SD 10.3). Mean time since diagnosis: 9.0 y (SD 7.4). Patients were treated with advice only (10.9%), advice plus either 1 OHA only (33.3%), 2 OHAs only (26.6%), ≥3 OHAs only (7.6%), or injectables with or without OHAs (21.6%). Treatment patterns varied considerably between countries. Mean HbA_{1c} of the entire group was 6.9% (SD 1.1). However, 36.7% of patients did not achieve an HbA_{1c} <7%. The figure shows the percentage of patients in each treatment category who did not achieve the target HbA_{1c} <7%.
Conclusion: When comparing the PANORAMA survey results with previous data, it appears that the level of glycaemic control in Europe may be improving. However, there is still a gap between current management and optimal treatment of patients with T2D. Furthermore, the percentage of patients not achieving target HbA_{1c} increased as treatment was intensified. Possible explanations are that concern over hypoglycaemia may have delayed treatment intensification, reduced treatment adherence or patients on more intensive treatment may have had more difficult to control T2D perhaps due to a longer duration of T2D. These results suggest that earlier and/or more effective intensification of treatment may be needed to enable patients to achieve target HbA_{1c} as the disorder progresses.

The Mapping Glycaemic Control Across Australia (MGCAA) study: a population based national diabetes surveillance study

C. Michaelides[1], M. Daja[2];
[1]Mater Hill Family Medical Centre, Brisbane, Australia, [2]Novo Nordisk, Sydney, Australia.

Background and aims: There are approximately 1.4 million Australians over the age of 25 with diabetes. More than half experience suboptimal glycaemic control, placing themselves at significant risk of complications and hospitalisation. Benchmarking glycaemic control is the first step in establishing a Diabetes Surveillance System, which allows for the development of targeted interventions to regions with the greatest need, as well as the subsequent monitoring of any intervention success. In Australia, previous studies have provided good quality data benchmarking glycaemic control at a national level. However, none have been able to benchmark, quantitate or qualify glycaemic control geographically at a national, state, Division of Primary Care and postcode level. Furthermore, none have been inclusive of demographic, clinical and biochemical markers. Considering the population diversity in a country as large and geographically diverse as Australia, such information is critical to the optimisation of diabetes resource management. The MGCAA study has achieved this.
Materials and methods: De-identified data including HbA_{1c}, lipids, age and gender were collected from private pathology laboratories. The data were cleaned (duplicates and screening HbA_{1c} values removed) and stratified geographically, providing a community population sample of approximately 250,000 diabetes patients. Demographic data including socioeconomic, lifestyle and cultural data were obtained and incorporated into the sample. The data were reported at a national, state and division of primary care regional level and made available via electronic mapping tools. Data from this first year of collection were regarded as benchmark data. Data were collected the following year and the cohort identified in year 1, were tracked and analysed, establishing a diabetes surveillance system. This is the first of a 5 year follow up period.
Results: Of the original 250,000 patient data collected in 2007, 56% had repeat data available in 2008 for follow-up (~140,000 patient samples), representing 10% of the estimated diabetes population of Australia. Although change in national glycaemic control was marginal (7.7% in 2007 vs 7.6% in 2008), there were clear regional differences in both mean HbA_{1c} as well the proportion of patients achieving HbA_{1c} targets (Fig 1). Regional differences were apparent with the proportion of these patients achieving HbA_{1c} glycaemic targets of <7% increasing in 4 states, remaining the same in 2 states and decreasing in 2 states.
Conclusion: The diabetes surveillance system can be interrogated to identify trends in glycaemic control, regional differences and those Divisions of Primary Care and the associated postcodes with the greatest glycaemic improvement (Fig 1) as well as those with the greatest need. Strategic interventions incorporating processes identified from areas with the greatest success can then be implemented and effectiveness monitored through prospective surveillance.

Development in quality of treatment and changes in treatment regimens in complicated type 2 diabetes

L. Lundby-Christensen, A. Anker-Nielsen, T.P. Almdal;
Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Optimal treatment of Type 2 Diabetes (T2D) relies on a multifactorial approach. Approximately 1800 patients with T2D are con-

trolled at the outpatient clinic at Steno Diabetes Center (SDC), which is a specialized diabetes hospital in Denmark. A high proportion of these suffers from one or more complications, i.e. app. 60% have micro or macro-albuminuria, app. 9% have undergone retinal laser treatment and app. 30% suffers from severe neuropathy. The purpose of this study was to assess to which degree the treatment goals as defined by ADA and documented in the Steno 2 study published 2003 is achieved, before and after the publication of these results.

Materials and methods: Patients treated at SDC have since 2001 all been registered in an electronic patient record system. All patients with T2D who have attended the outpatient clinic for ≥6 month in the years 2002, 2006 and 2009 were identified. The proportion of patients reaching ADA treatment goals with regard to HbA1c, blood pressure (BP) and lipids was identified as shown in the table. Furthermore, the proportion of patients receiving different antidiabetic treatment regimens (oral antidiabetics (OAD) only, insulin only or a combination of OAD and insulin) was identified.

Results: The survey shows that it was possible to achieve the treatment goals in the majority of the patients with regard to lipid levels and diastolic BP, whereas this was not the case with regard to systolic BP and HbA1c. However, it was possible to approximately double the proportion of patients achieving the treatment goal of HbA1c in the years 2002 to 2006. In the same period the proportion of patients receiving a combination of OAD and insulin increased by 13%, whereas the proportion of patients receiving insulin monotherapy decreased by 10%. The proportion of patients treated with either diet (3-4%) or OAD only (19-20%) was unchanged throughout the period. With regard to BP lowering agents the proportion of patients receiving two or more agents increased from 55 to 67% in the period whereas the proportion of patients receiving lipid lowering medication increased from < 40% to >80% (data not shown).

Conclusion: The results suggest that in patients with complicated T2D it is possible to achieve near optimal results with regard to lipid levels and diastolic BP and acceptable control with regard to systolic BP. With regard to glucose control, it is possible to markedly increase the proportion of patients achieving treatment goal, however, even more focus is needed.

Changes in treatment regimens and achievement of clinical goals provided in percentages of patients

Year	Treatment with OAD only	Treatment with insulin only	Treatment with OAD +insulin	HbA1c ≤ 7.0%	Diastolic BP ≤ 80 mmHg	Systolic BP ≤ 130 mmHg	Total cholesterol ≤4.5 mmol/l	LDL cholesterol ≤2.5mmol/l
2002	20	48	28	15	60	27	35	44
2006	19	38	41	28	68	27	70	80
2009	20	39	39	25	66	38	71	79

1015

Socio-economic status, incidence of type 2 diabetes and relative mortality in Scotland 2001-2007

S.H. Wild, Scottish Diabetes Research Network Epidemiology Group; Centre for Population Health Sciences, University of Edinburgh, United Kingdom.

Background and aims: Relative risks of mortality associated with type 2 diabetes (T2DM) have declined in recent years but are higher in women than men in many populations. The role of socio-economic status (SES) in risk of mortality among people with diabetes is not clear.

Materials and methods: We used data from a population-based national diabetes register to investigate the associations between T2DM, socio-economic status (SES) and mortality. SES was categorised with Q5 and Q1 representing the most deprived and most affluent quintiles from an area-based measure. Age-standardised incidence for 2004 and relative risks (RR) for all-cause mortality among people with incident T2DM of 35 to 84 years of age between 2001 and 2007 were estimated using general population data, the European standard population and Poisson regression models.

Results: Complete data were available for 111,441 people who developed type 2 diabetes between 2001 and 2007 and there were 8,775 deaths before the end of 2007. SES had a more marked effect on age-standardised incidence among of T2DM women (717.5 vs 357.2 per 100,000, age-adjusted RR for Q5 vs Q1 (95% confidence interval [CI]) 1.91 (1.62-2.25)) than men (comparable estimates 918.6 vs 568.9 per 100,000, 1.59 (1.38-1.84)). Age and SES adjusted RR (95% CI) for mortality were 0.97 (0.93 to 1.01) for men and 1.11 (1.07 to 1.16) for women. Age and sex adjusted RR for mortality associated with type 2 diabetes was lower for Q5 (0.93 (0.89-0.97)) than for Q1 (1.19 (1.12 to 1.27)).

Conclusion: Relative risks for mortality associated with incident T2DM were lower in this population than reported in previous studies. Incident diabetes was not associated with increased mortality among men but was associated with higher mortality in women compared to women without diabetes. SES modifies the effect of T2DM on mortality but does not explain sex differences in RR. Further work is required to establish whether these findings can be explained by risk factor patterns.

The national inpatient diabetes audit reveals poor levels of inpatient foot care

G. Rayman[1], C.G. Taylor Jr.[1], R. Malik[2], R. Hilson[3];
[1]The Diabetes Centre, Ipswich Hospital, [2]Kings College Hospital, London, [3]The Department of Health, London, United Kingdom.

Background and aims: The standards of expected inpatient foot care have been recently outlined in the document "Putting feet first" however there has been no previous national assessments of the burden or quality of inpatient foot care.

Materials and methods: A national audit of clinical care was undertaken in acute hospitals in the UK on a single day between the 21st and 25th of September to determine diabetes prevalence, quality of care and patient experience. The audit form included key questions related to areas of foot care. The National Diabetes Inpatient Audit Day database was analysed to assess the standard of foot care.

Results: 14,259 patients in 219 hospitals were audited. 11.6% had a past history of foot disease. When diabetes was the primary reason for admission a foot problem was the most frequent diagnosis (24.9%), yet only 79% were referred to the foot team. 26% of hospitals did not have a multidisciplinary foot team. Mean length of stay was 22 days for those admitted with a foot complication compared with 15 days for other diabetes related admissions. Only 34% of patients recalled a visual foot inspection and only 30% a physical foot examination. In-hospital foot complications developed in 3%.

Conclusion: The figures are concerning. The audit confirms the significant inpatient burden of foot disease but also a disturbingly poor level of foot care. The results support the urgent need to implement foot awareness programmes such as "Putting Feet First".

1017

Clinical inertia in patients with type 2 diabetes and poor glycaemic control in a multicentric sample of patients cared for in primary in Catalonia (Spain)

B. Benito-Badorrey[1], M. Mata-Cases[1], P. Roura-Olmeda[1], G. Coll de Tuero[2], J. Pepió-Vilaubí[2], J. Franch-Nadal[1], Gedaps (Primary Care Group for the Study of Diabetes). Catalonian Society Family & Community Medicine; [1]Gedaps, [2]Camfic, Barcelona, Spain.

Background and aims: To assess clinical inertia (the providers' failure to increase therapy when treatment goals are unmet) in patients with type 2 diabetes (DM2) cared for in primary care.

Materials and methods: A multicentric cross-sectional study. Clinical inertia, defined as absence of modification of the treatment in patients with HbA1c> 7 %, was assessed in a random sample of patients with DM2 cared for in 52 primary care centres of Catalonia (Spain) in 2007.

Results: A total of 3130 patients were evaluated of whom 2783 had some HbA1c value. Of these, 997 had an HbA1c>7 %; 51.1 % males; mean age 67.1 years, standard deviation (SD) 12.1; 8.2 years of diabetes evolution-SD 6.3. Some changes were made in 66.8% patients: insulin dose increase in 40.5%, the addition of an oral agent in 45.8% or the start of insulinization in 3.7%. The mean value of HbA1c in patients for whom treatment was changed was 8.4%. Clinical inertia was observed in 33.2% of patients (CI95% 30.31-36.1); decreasing with the complexity of treatment: diet 38,8% (CI95% 20.2-57.4%), a single oral drug 40.3% (CI95% 35.2-45.4), two or more oral agents 34,5% (CI95% 23,3-45,7), insulin in monotherapy 26.1% (CI95% 18,2-34.0) and insulin plus oral agents 21.4% (CI95% 20,9-33,3). Clinical inertia decreased

as HbA1c increased: 37.3% (CI95% 33.2-41.4) between 7.1 and 8%; 29.4% (CI95% 23.5-34.9) between 8.1 and 9% and 27.1% (CI95% 20.9-33.3) if ≥9%. There were no differences in the characteristics of the patients in which the treatment was modified or not. The greatest opportunity for improvement lies in patients treated with diet or oral monotherapy (40.5%)
Conclusion: Clinical inertia affects a third of diabetic patients with poor glycemic control and is more related to a close to objective HbA1c value than to the complexity of the treatment or the patient characteristics. The changes are introduced with a mean HbA1c well above the therapeutic goal.

1018

Poor glycaemic control in secondary care insulin treated patients correlates with bad process indicators

N. Debacker[1], P. Van Crombrugge[2], C. Mathieu[3], F. Nobels[2], V. Van Casteren[1], A.J.L. Scheen[4];
[1]Public Health & Surveillance, Scientific Institute of Public Health, Brussel, [2]Endocrinology, OLV Ziekenhuis, Aalst, [3]Experimental Medicine and Endocrinology, KU Leuven, [4]Division of Diabetes, Nutrition, and Metabolic Disorders, CHU Sart Tilman, Liège, Belgium.

Background and aims: Evidence based medicine and quality control systems drive diabetes care, but room for improvement, not only in glycemic control, but also in follow up of other outcome and process indicators, exists. In the present study we examine how glycemic control is related to other outcome and process indicators.
Materials and methods: We used the 2009 data from a Belgian quality assurance study that has been carried out since 2001 in all hospital-based diabetes centres (n=113) and provides data (demographics, blood glucose control, cardiovascular risk status, diabetes complications, self-monitoring, and drug treatment) on a cross-sectional random 10% sample of the adult type 1 and type 2 diabetes patients on ≥ 2 daily insulin injections. Logistic regression analysis was used to examine the relationship of HbA1c with 5 process and 5 outcome indicators, while adjusting for age, diabetes duration and gender.
Results: In the type 1 diabetes population (n=3407; 57% males) the median age, diabetes duration and HbA1c were 47 years, 17 years and 7.8%, respectively. In the type 2 diabetes population (n=7879; 49% males) the median age, diabetes duration and HbA1c were 69 years, 14 years and 7.5%, respectively. Table 1 shows the performance in terms of process and intermediate outcome by HbA1c and diabetes type (Table legend: (1) $p<0.05$; (2) $p<0.01$; (3) $p<0.001$: Results from logistic regression analysis, after adjustment for age, gender and diabetes duration. HbA1c < 7% is used as reference.). Especially in type 2 and to a minor extent in type 1 diabetes, patients with the worst glycemic control (HbA1c ≥ 9%) were significantly less likely to be screened for complications (except for microalbuminuria screening) than the patients with optimal glycemic control (HbA1c < 7%). In both diabetes types, patients with suboptimal glycemic control (HbA1c ≥ 7%) were significantly less likely to reach blood pressure and blood lipid targets compared to patients with optimal glycemic control. Moreover in type 1 diabetes the proportion of smokers increased significantly with increasing HbA1c. These results were independent of age, diabetes duration and gender.
Conclusion: Quality of care in this population of diabetes patients with advanced disease stage was relatively good in terms of process and intermediate outcome. However suboptimal glycemic control was found to go hand in hand with poorer results for both other outcome and process indicators. The identification of patients characterised by this cluster of poor performance and of the causal factors merits further investigation.

1019

Fifteen years of improvement in process and outcome indicators in the management of type 2 diabetes mellitus in primary care centres in Catalonia, Spain

M. Mata-Cases[1], B. Benito-Badorrey[1], P. Roura-Olmeda[1], G. Coll de Tuero[2], J. Pepió-Vilaubí[2], J. Franch-Nadal[1], Gedaps (Primary Care Group for the Study of Diabetes). Catalonian Family &Community Medicine Society;
[1]GEDAPS, [2]Catalonian Family & Community Medicine Society, Barcelona, Spain.

Background and aims: To assess the evolution of the quality indicators of type 2 diabetes care in Primary Health Care centres in Catalonia over 15 years (1993-2007).
Materials and methods: A multicentric cross sectional study with the same sampling methodology in 7 evaluations. Continuous quality improvement program of GEDAPS (Primary care Group for the study of Diabetes) from the Catalonian Society of Family and Community Medicine. Assessment of the process and outcomes indicators in a randomized sample from each centre. Number of participating centres: 57 in 1993, 75 in 1995, 75 in 1998, 78 in 2000, 96 in 2002 and 52 in 2007. Sample sizes: 2239 in 1993, 3532 in 1995, 4217 in 1998, 45667 in 2000, 5819 in 2002 and 3130 in 2007.
Results: We observed a significant improvement in the following process indicators: foot examination from 49% (CI95% 46.9-51.1) to 64% (CI95% 62.3-65.7); laboratory measurements: HbA1c from 69% (CI95% 67.1-70.9) to 89% (CI95% 87.9-90.1), cholesterol from 76% (CI95% 74.2-77.8) to 91% (CI95% 90.0-92.0) and albuminuria from 34% (CI95% 32.0-35.9) to 59% (CI95% 57.3-60.7). A significant improvement in intermediate outcome indicators was seen in glycemic control (HbA1c <7%) from 39% (CI95% 37.0-41.0) to 65% (CI95% 63.3-66.7) and cholesterol (total cholesterol <200 mg / dl) from 26% (CI95% 24.2-27.8) to 61% (CI95% 59.3-62.7). There was no change in the strict control of blood pressure (BP <130/80 mmHg) 22% vs 21%, but an improvement was seen with a less stringent criteria (BP <140/90 mmHg) 45% (CI95% 42.3-47.1) vs 57% (CI95% 55.3-58.7). We observed a significant reduction in the prevalence of the following final outcome indicators: foot ulcer 7.9% (CI95% 6.8-9.0) vs 2.6% (CI95% 2.0-3.2), amputation 2.1% (CI95% 1.5-2.7) vs 0.6% (CI95% 0.3-0.9) and retinopathy 37% (CI95% 35.0-39.0) vs 15% (CI95% 13.7-16.2).
Conclusion: There were significant improvements in some of the process indicators, the glycemic, blood pressure and lipid control and a decrease in complications like retinopathy and diabetic foot.

PS 96 Monitoring and delivering: practicalities for every day practice

1020

Use of an alcohol-based hand sanitiser did not affect readings of a blood glucose monitoring system

D. Price, J. Mahoney, J. Ellison, C. Chu, S. Nandagopalan, J.P. Frias;
LifeScan, Inc., Milpitas, USA.

Background and aims: People with diabetes mellitus (DM) are instructed to wash their skin with soap and water prior to self-monitoring of blood glucose (BG) to remove any dirt or food residue that might alter the reading. Alcohol-based hand sanitizers have become popular when soap and water are not available. The aim of this study was to determine whether the use of a common hand sanitizer has any effect on BG results from a meter system.
Materials and methods: We enrolled 34 non-fasting subjects (14 male/20 female, mean age 45(SD: 9.4)y, 2 with DM). Laboratory personnel prepared four separate fingers on one hand of each subject by: 1) washing with soap and water and towel drying (control finger); 2) cleaning with hand sanitizer (Purell® Instant Hand Sanitizer with Aloe, active ingredient 65% ethyl alcohol, Johnson & Johnson Consumer Products, Skillman, NJ) per instructions (Purell finger); 3) coating with cola (Coca-cola, Coca-Cola Company, Atlanta, GA) and air drying (cola finger); and 4) coating with cola and cleaning with Purell after cola dried (Purell after cola finger). Fingersticks were performed on each prepared finger and BG was measured with the OneTouch® Ultra® Blood Glucose Monitoring System (LifeScan Inc., Milpitas CA). YSI plasma glucose was also measured using the control finger. BG tests, shown in the table, were completed within 10 minutes.
Results: Mean BG values from the Purell finger and Purell after cola finger did not differ significantly from the Control finger (p=0.07 and 0.08, respectively). Cleaning with Purell resulted in 100% and 99% accurate readings versus YSI based on ISO 15197 and consensus error grid (zone A) analysis, respectively. Cola finger BG was substantially higher than the other skin conditions. In 16 cases, cola residue caused blood samples to smear and produce error messages and in 3 cases, cola residue caused BG values > 600 mg/dL (excluded).
Conclusion: In our study, cleaning with Purell hand sanitizer did not affect fingerstick BG tests performed with the OneTouch® Ultra® System.

Table: Glucose Mean (SD), N, and Finger Condition after Preparation (as described).

Finger Skin Condition	N	Glucose, Mean (SD), mg/dL
Control finger	34	100.6 (16.5)
Purell finger	34	103.6 (17.1)
Cola finger	15	182.9 (102.8)
Purell after Cola finger	34	103.8 (17.4)

1021

Improving the reliability of capillary blood glucose monitoring: using the first or second drop of blood

J. Hortensius[1], R.J. Slingerland[2], M.J. Fokkert[2], N. Kleefstra[1], K.H. Groenier[3], S.T. Houweling[4], R.O.B. Gans[5], H.J.G. Bilo[1];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Clinical Chemistry, Isala Clinics, Zwolle, [3]General practice, University of Groningen, [4]General practice, Sleeuwijk, [5]Internal Medicine, University Medical Center, Groningen, Netherlands.

Background and aims: Self monitoring of blood glucose (SMBG) is an important tool to achieve good glycemic control. Several aspects concerning SMBG need attention. Eg, there is no general agreement regarding the use of the first or second drop of blood for glucose monitoring. Various international studies and recommendations, advise to use the first drop of blood, after washing hands with water and soap. Still, in daily practice patients can not or do not always wash their hands. Our aim was to investigate the influence of having clean or soiled hands on glucose concentration in the first and second drop of blood.
Materials and methods: Eligibility criteria were patients with diabetes mellitus type 1 (T1DM) or type 2 (T2DM), using insulin, age above 18 years. A cross-sectional, 'within subjects' design was used. Wilcoxon Signed Rank Test was used to test for differences in glucose concentrations. Capillary glucose concentrations were measured in two consecutive drops of blood in the following three circumstances. Firstly, without washing hands, secondly, after washing hands with water and soap, and thirdly, after soiling the fingers with apple or banana. Results were compared to a control measurement in each finger used in the study. Results were also assessed, looking at the frequency of differences ≥ 10 % higher glucose concentrations vs control.
Results: Recruitment took place between September 2009 and January 2010. Our study population consisted of 123 patients, 63 (51%) men, 66 (54%) T1DM patients, and 57 (46%) T2DM patients, mean age was 54,4 years (SD 14,2) mean HbA1c was 58 mmol/mol (or 7,5% SD 1,3) and mean BMI was 29 kg/m² (SD 6,2). The table shows glucose concentrations for the three different circumstances. Not washing hands led to more than 10% higher glucose concentrations in the first and in the second drops of blood in 10% of the patients (p<0.001). Fingers soiled with fruit led to more than 10% higher glucose concentrations in the first and in the second drop of blood in 91% and 13% of the patients, respectively (p<0.001 and p=0.002 respectively). After washing the soiled fingers, glucose concentrations were more than 10% higher in 2% and 4% of the patients, respectively. In 2 - 3% of the patients the glucose concentrations in the first drop of blood of clean hands were 10% higher than in the second drop of blood (not significant).
Conclusion: The first drop of blood of unclean hands should not be used to allow a reliable glucose measurement. Although wiping the first drop of blood of unclean hands improves readings considerably, in 10 - 13% of the patients the glucose concentrations are still 10% higher than the control measurement. The first drop of blood can probably only be used when the fingers are clean.

glucose concentrations (mmol/L) and median (interquartile ranges) in different circumstances

	first drop of blood	second drop	control
not washing hands	8.9 (6.4 - 12.6)	8.9 (6.5 - 12.3)	8.7 (5.9 - 12.2)
washing hands	8.5 (6.3 - 12.2)	(is control)	8.7 (5.9 - 12.2)
soiled finger	15.0 (10.5 - 21.7)	8.8 (6.5 - 12.4)	8.9 (6.4 - 12.3)
washing hands after soiling the finger	8.3 (6.3 - 11.9)	8.2 (6.3 - 12.0)	8.6 (6.2 - 12.0)

The effect of haematocrit on the results of measurements using glucose meters based on different techniques

B. Solnica[1], B. Kusnierz-Cabala[1], K. Slowinska-Solnica[1], J. Skupien[2], P. Witek[3], A. Cempa[3], M.T. Malecki[3];
[1]Dept. of Diagnostics, Jagiellonian University Medical College, Krakow, Poland, [2]Joslin Diabetes Center, Harvard Medical School, Boston, USA, [3]Dept. of Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland.

Background and aims: Hematocrit (HT) affects the measurement accuracy of glucose meters. Glucose concentrations measured in samples with high HT values are decreased whereas in samples with low HT are increased as compared to the laboratory method. This effect caused mainly by plasma displacement may vary between different devices. The aim of the study was to evaluate the effect of HT on glucose meter assays based on different measurement techniques.
Materials and methods: We studied glucose meters utilizing the glucose dehydrogenase reaction and four measurement techniques. The HemoCue (HemoCue AB) uses colorimetry, the Accu-Chek Active (Roche Diagnostics) - reflectometry, The Optium Xido (Abbott Diabetes Care) - amperometry and the Optium Omega - coulometry. EDTA venous blood samples with glucose concentrations ranging from 40 to 412 mg/dL were used. We modified the samples HT by adding or removing defined aliquots of plasma. Glucose concentrations measurements were performed using each evaluated meter in 27 batches, each containing 5 blood samples with HT amounting to 20%, 30%, 40%. 50%, and 60%. Altogether, 540 glucose assays (108 batches) were performed.
Results: A significant relationship between HT and glucose reading in all meters was found - the relative decrease in glucose concentration per 1% increase in the HT value amounted from 0.51% for Optium Omega to 1.28% for Optium Xido (p<0.0001). Moreover, for all meters, except Optium Xido, there was a significant modification of this relationship by glucose level. The mixed effects model after logarithmic transformation of glucose concentra-

tions, stratified by glucose level (200 mg/dL) showed a significant (p<0.0001) relative decrease in glucose level per 1% increase in HT for all meters in all strata ranging from 0.30% for Optium Omega in stratum <100 mg/dl to 1.32% for HemoCue in the same stratum. According to the ADA recommendations, the glucose meter error should not exceed 5%. In <100 mg/dL stratum this threshold would be reached after about 3.6% to 4.1% HT change in all meters except of Optium Omega, for which a change of 16.6% would be needed (p<0.0001). In 100-200 mg/dL stratum Optium Xido reached the error threshold after 4.2% change in HT, compared to values in the range of 7.9% to 11.1% for other devices (p200 mg/dL stratum, similarly, Optium Xido reached this threshold after 3.9% change in HT (p<0.0001), while for the other meters it varied from 7.2% to 12.5%.

Conclusion: There is a significant continuous effect of HT on measurement accuracy of glucose meters across the wide range of HT values and glucose concentrations. Amperometric measurements seem to be more sensitive, while the coulometric technique appears to be less sensitive to the HT interference than photometric techniques.

1023

Use of GDH-PQQ glucose meter systems in patients receiving maltose-containing therapies

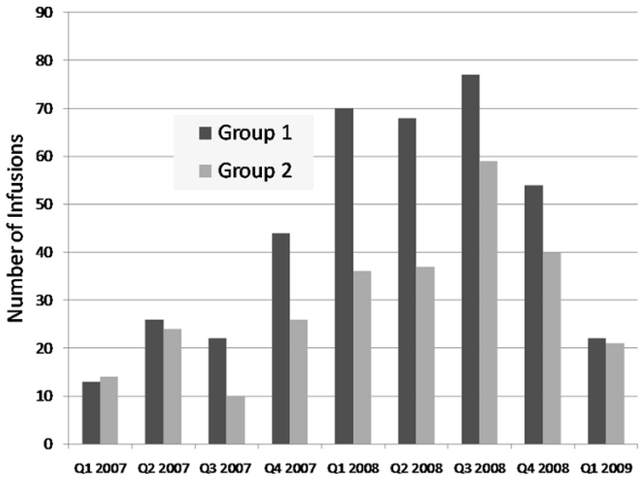
N.S. Virdi[1], D. Price[1], J. Ellison[1], S. Yadalam[2], S. Nigam[2];
[1]LifeScan, Inc, Milpitas, [2]Johnson &Johnson, New Brunswick, USA.

Background and aims: Blood glucose measurement (BGM) systems utilizing the enzyme, glucose dehydrogenase pyrroloquinoline quinone (GDH-PQQ), have lead to falsely elevated "glucose" readings in patients on medications containing maltose or a maltose precursor. Examples include icodextrin (a peritoneal dialysate metabolized to maltose), and OCTAGAM® and abatacept, which contain maltose as excipients. Over the past 10 years FDA's MAUDE Database and the literature have included multiple reports of severe hypoglycemia and death related to overtreatment with insulin or delayed detection of hypoglycemia, because of falsely high readings on GDH-PQQ meters. We reviewed a payor database to assess how frequently patients receiving OCTAGAM or abatacept also use a GDH PQQ meter system . Data were not available for peritoneal dialysis and limited for other maltose-containing therapies.

Materials and methods: The analysis used the Thomson Reuters Marketscan Database (years 2007 through Q1 2009), a large U.S. administrative claims database representing about 35.7 million employed, commercially-insured persons. We queried for persons with diabetes using glucose meters. This population was divided into three groups: Group 1 - Patients using only GDH-PQQ meters, Group 2 - Patients using only non-GDH-PQQ meters, and Group 3 - Patients using both GDH-PQQ and non-GDH-PQQ meters. The query identified patients who had received abatacept or OCTAGAM and ordered BGM test strips during the same quarter. As each quarter in the database is updated over time, the most recent quarters may be incomplete.

Results: The search identified 798,110 patients ordering BGM test strips during the two and one-quarter year period: 40.7% in Group 1, 54.7% in Group 2, and 4.6% in Group 3. Of these patients, 366 had also received abatacept or OCTAGAM infusions: 43.2% in Group 1, 45.6% in Group 2, and 11.2% in Group 3. Including those not using BGM, 5503 patients had received abatacept or OCTAGAM. The chart below compares the number of infusion events per group over the period Q1/2007 - Q1/2009. The majority (60%) of infusions were associated with Group 1 vs. 40% for Group 2. During the time period of observation, no decrease in the proportion of infusions associated with GDH-PQQ meters has occurred.

Conclusion: This study demonstrated that patients with diabetes on therapy with either abatacept or OCTAGAM frequently use GDH-PQQ meters, which are susceptible to maltose interference. Despite labeling (on both BGMs and medications) and FDA safety alerts, there is evidence that health care professionals and patients continue to prescribe and use, respectively, BGM systems susceptible to maltose interference despite patient exposure to therapies containing maltose. While use of abatacept and OCTAGAM is limited, the common usage of GDH-PQQ meters by patients taking these medications puts them at risk for obtaining falsely elevated blood glucose results that may contribute to or delay detection of hypoglycemia.



1024

Comparison of insulin diluent leakage post injection using two different needle lengths and injection volumes in obese patients with type 1 or type 2 diabetes mellitus

K.R. Kelly[1], S. Sarwat[1], M.A. Carey[2], D.A. Ignaut[1];
[1]Eli Lilly and Company, Indianapolis, [2]i3 Statprobe/UHG, Minneapolis, USA.

Background and aims: Although the current market offers several different needle lengths for the injection of insulin, obese patients with diabetes are often advised to use longer needles (≥8-mm). Smaller, shorter needles have been shown to be safe and effective for insulin delivery while reducing patient discomfort. This study compared injections with 5-mm needles to injections with 8-mm needles regarding leakage, blinded pain, bleeding, and bruising at abdominal injection sites in obese patients with diabetes.

Materials and methods: Patients (n=56; 54% male; mean age=56; mean BMI=36 kg/m^2; insulin pen-naïve) with type 1 (n=13) or type 2 (n=43) diabetes participated in a randomised feasibility trial with patients blinded to needle length. Patients were injected by the investigator 3-5 times (to obtain 3 injections without bleeding to accurately measure leakage) in the abdomen with either 20 U equivalent (200 µL) volumes or 60 U equivalent (600 µL) volumes of sterile insulin diluent with both a 5-mm and 8-mm needle using a conventional insulin pen injector, HumaPen® Memoir™. The primary objective was to evaluate leakage at the injection site (by blotting with filter paper and weighing the filter paper using a tared, calibrated analytical balance) following injections (20 U and 60 U equivalent volumes) with 5-mm and 8-mm needles using a 4-step gatekeeping strategy. The success criterion for each gatekeeping step was defined such that the upper limit of the 90% CI for median leakage was <5% of the injected volume. Non-inferiority of 5-mm needle leakage compared to 8-mm leakage was evaluated with similar methodology. Secondary objectives were to compare injections (20 U and 60 U equivalent volumes) with 5-mm and 8-mm needles for blinded pain, bleeding, and bruising at injection sites.

Results: Leakage with the 5-mm needle for both the 20 U and 60 U equivalent volumes was <5% of the total volumes and was non-inferior to the 8-mm needle (see table). Pain scores were numerically similar for both needles (see table). Proportions of injections with bleeding (5-mm/20 U, 10.5%; 5-mm/60 U, 4.9%; 8-mm/20 U, 5.8%; 8-mm/60 U, 6.6%) and proportions of patients with bruising (5-mm/20 U, 8.1%; 8-mm/20 U, 10.8%, p=0.6; 5-mm/60 U, 21.1%; 8-mm/60 U, 26.3%, p=0.7) at injection sites were similar.

Conclusion: The results of this study support the suitability of the 5-mm needle for the injection of insulin in obese patients with diabetes with regard to leakage, pain, bleeding, and bruising at abdominal injection sites.

Needle Length (mm)		5	5 minus 8*	5	5 minus 8*

Safety evaluation of a new reusable insulin pen (ClikSTAR®) in 2526 Canadian patients (pts) with type 1 and type 2 diabetes mellitus (DM) receiving insulin glargine

I. Gottesman[1], P. Perron[2], L. Berard[3], J. Stewart[4], K. Mettimano[5];
[1]University of Toronto, Mississauga, [2]Sherbrooke University, Sherbrooke, [3]Diabetes Research Group, Health Sciences Centre, Winnipeg, [4]Sanofi-aventis, Laval, [5]Signature Medicine Centre Pharmacy, Calgary, Canada.

Background and aims: Insulin pens have increased the convenience, accuracy and flexibility of insulin therapy in comparison with traditional vial and syringe administration. ClikSTAR® is a novel reusable insulin pen developed for use with insulin glargine and insulin glulisine. The aim of the study was to assess the safety profile of ClikSTAR® after 6-12 weeks of use in type 1 & type 2 DM pts receiving insulin glargine.
Materials and methods: In this open-label, multicenter, non-randomized, uncontrolled, observational, prospective study pts with type 1 & type 2 diabetes receiving insulin glargine were eligible to participate. At baseline all pts received the ClikSTAR® pen, instruction leaflet and a free-toll number for Technical Support and had been trained on the pen use with insulin glargine cartridges. Baseline information was collected at the first visit. A follow-up visit assessment was performed by investigators at 6-12 weeks to collect any Product Technical Complaint (PTC). PTCs could be reported throughout the study and investigators used a decision tree guide to handle PTCs. All pens associated with a PTC were tested for Product Technical Failure (PTF) at the pen laboratory in Frankfurt. The risk acceptance criterion was that no validated PTF leading to a Serious Adverse Event (SAE) would occur within 2500 pts during a period of 6 to12 weeks.
Results: 2526 pts were enrolled (56% male and 44% female) in 104 sites across Canada, average age was 56 (SD = 14) years, 31% were type 1 DM and 69 % type 2 DM. 93% of pts were pen users prior to study enrolment. 9% and 8% had visual and dexterity impairment respectively. A total of 84 PTCs, 24 SAEs and 85 non serious adverse events (AEs) were reported. 3 pts with SAEs and 9 with AEs were reported as having a causal relation with a PTC. Investigation results of PTCs associated with an SAEs showed that they were not due to a pen failure. A total of 75 (3%) pts withdrew from the study; 15 for a PTC and 19 for an AE. The most common PTCs were related to the plunger, the dose selector and insulin delivery. No PTF related to an AE or SAE identified throughout the study and most PTCs were due to handling error of the pen and not requesting additional information or assistance from their site personnel or the Call Center.
Conclusion: This first real life observational safety study had been designed to collect complaints and adverse events reported by pts with diabetes using ClikSTAR® pen and insulin glargine. PTCs were infrequent and No PTF related to an AE or SAE reported. Results show that this new reusable pen is safe to be used with insulin glargine.

PS 97 Education: in the right hands - an effective therapy for diabetes

1026

Rapid reductions in insulin requirements in patients with type 1 diabetes participating in the DAFNE (Dose Adjustment for Normal Eating) structured education programme

L. Leelarathna[1], C. Ward[2], F. Finucane[3], K. Davenport[2], A. Housden[2], M.L. Evans[1];
[1]Institute of Metabolic Science, University of Cambridge & Cambridge University Hospitals NHS Foundation Trust, [2]Wolfson Diabetes Clinic, Cambridge University Hospitals NHS Foundation Trust, [3]MRC Epidemiology Unit, Institute of Metabolic Science, Cambridge, United Kingdom.

Background and aims: The Dose Adjustment for Normal Eating (DAFNE) programme consists of 4.5 days of structured education for patients with type 1 diabetes (T1D), to enable them to adjust their own insulin doses as required. This programme has previously been shown to lower HbA1c, reduce the incidence of hypoglycaemia and improve quality of life. There is anecdotal evidence that these improvements are associated with significant reductions in insulin doses, suggesting that some are over-insulinised prior to the programme. However, to date no formal analysis of changes in insulin doses associated with participation in DAFNE training has been conducted. We sought to determine whether DAFNE training is associated with changes in insulin requirements.
Materials and methods: We conducted a retrospective cohort analysis of adults with T1D who attended DAFNE training in our centre between October 06 and December 09. The type and dose of insulin used at the pre-course assessment and on the fourth day of the DAFNE course were recorded. HbA1c at the pre-course assessment and the first measured HbA1c between 3 and 12 months after completion of the course were also recorded, as was the presence of clinically apparent lipohypertrophy(LH). Data are presented as means ± SD. A two-tailed t-test was used to compare pre- and post- DAFNE training variables.
Results: Over the three year study period, 335 patients underwent DAFNE training at our centre. Complete pre-course and follow-up data were available for 259 patients (77%) and these were included in the current analyses. 124(48%) were female, 97% were Caucasian, mean age was 41 ± 14 years (range 18- 74) and mean duration of diabetes was 19 ± 14 years. 43.1 % of patients had documented LH. There were significant reductions in daily total insulin (52 ± 22 to 44 ±16 units), quick acting insulin (28 ±14 to 24 ±9) and basal insulin (24 ±12 to 20 ± 10) on day 4 of DAFNE training compared to the pre-course doses (all $p<0.001$). The dose reduction was greater in patients with LH than in those with no LH (10.1 and 6.5 units, respectively). However, the insulin dose reductions were statistically significant even in those with no LH ($p < 0.001$). Most patients were using insulin analogues (Insulin Aspart 66%, Insulin Lispro 25%, Insulin Glargine 65%, Insulin Detemir 22%). We estimate that the 16% reduction in total daily insulin dose would lead to an annual reduction in insulin cost of approximately 90GBP (100 euro), based on current drug costs. Importantly, insulin dose reduction did not worsen glycaemic control, with a small trend for HBA1c to improve when first checked after DAFNE (8.4 ± 1.3 vs 8.30 ± 1.2 pre vs post-course, $p =0.11$).
Conclusion: We observed significant reductions in the short term in insulin requirements in T1D patients undergoing DAFNE training. Although it is possible that changes in physical activity during the course may have contributed, the changes seen likely reflect more appropriate insulinisation of these patients, which would account for reductions in hypoglycaemia. Our data suggest that patients with T1D who do not have access to structured education may be systematically over treated with insulin.

1027

Lifestyle intervention by group-based rehabilitation versus individual counselling in type 2 diabetes: 1-year follow-up

E.S. Vadstrup[1], A. Frølich[2], H. Perrild[1], E. Borg[3], M. Røder[4];
[1]Dept of Endocrinology and Gastroenterology, Bispebjerg Hospital, Copenhagen NV, Denmark, [2]Department of Integrated Healthcare, Bispebjerg Hospital, Copenhagen, [3]Health Care Centre Oesterbro, Copenhagen, [4]Department of Cardiology and Endocrinology, Hillerød University Hospital, Denmark.

Background and aims: To compare the longer term effectiveness of delivering lifestyle intervention to type 2 diabetes patients as either group-based rehabilitation in primary care or individual counselling in an outpatient setting.
Materials and methods: We randomised 143 patients with type 2 diabetes to a 6-months group-based rehabilitation programme, including patient education, supervised exercise, and diet intervention, or to a 6-months individual counselling programme. Follow-up time was 12 months after baseline. Outcome measures were glycated haemoglobin (HbA_{1c}), cardiovascular risk factors, quality-of-life (SF-36, Medical Outcomes Study Short Form 36-item Health Survey) and self-rated health (DSC-R, Diabetes Symptom Checklist - Revised).
Results: In the rehabilitation group there was a decrease in HbA_{1c} (-0.2%-point, 95%CI [-0.4 to 0.03]), systolic blood pressure (-6 mmHg [-9.3 to -2.5]), diastolic blood pressure (-4 mmHg [-6.3 to -2.4], weight (-2.2 kg [-3.2 to -1.3]), and waist circumference (-2.0 cm [-2.9 to -1.1]). In the individual group there was a decrease in HbA_{1c} (-0.4%-point [-0.6 to -0.1]), systolic blood pressure (-3 mmHg [-6.3 to 0.7]), diastolic blood pressure (-3 mmHg [-4.7 to -0.7]), weight (-1.6 kg [-2.6 to -0.7]), and waist circumference (-1.6 cm [-2.5 to -0.6]). Self-rated vitality, fatigue distress, physical functioning and cardiovascular distress improved over time ($P<0.05$) in the two groups combined. Repeated measurement analysis did not result in significant differences between the groups of *any* outcome.
Conclusion: There were no significant differences between the two groups over time, but improvements in HbA_{1c}, blood pressure, weight, waist circumference, self-rated vitality and fatigue distress in the two groups combined were significant. However, the resource use of the rehabilitation programme was twice as much as the individual programme.

Randomised controlled trial of the DESMOND structured education programme for people newly diagnosed with type 2 diabetes: biomedical outcomes, psychosocial measures and illness beliefs at three years

K. Khunti[1], S. Heller[2], T.C. Skinner[3], L.J. Gray[1], H.M. Dallosso[4], K. Realf[4], M.E. Carey[4], M.J. Davies[5];
[1]Health Sciences, University of Leicester, United Kingdom, [2]University of Sheffield, United Kingdom, [3]Combined Universities Centre for Rural Health, Geraldton, Australia, [4]Diabetes Research, University Hospitals of Leicester, United Kingdom, [5]Cardiovascular Sciences, University of Leicester, United Kingdom.

Background and aims: DESMOND is a structured group self-management education programme (6 hours contact time) for patients newly diagnosed with type 2 diabetes. A multi-site cluster randomised controlled trial showed that DESMOND is associated with benefits in illness beliefs, weight loss, physical activity, smoking and depression. A three year follow-up of the participants has been carried out to see if these benefits are sustained beyond 12 months and the results are reported.
Materials and methods: Participants in the original trial who were eligible for follow-up at 3 years were sent a postal questionnaire (illness beliefs, symptoms of depression, quality of life, physical activity and smoking) and asked to visit their practice for biomedical measures (HbA1c, blood pressure, weight, blood lipids, waist circumference).
Results: Of the 743 people eligible for follow-up, biomedical data were collected on 604 (81.3%) and questionnaire data on 513 (69.0%). No statistically significant differences in biomedical measures were seen at 3 years, although a trend to greater improvement across all biomedical factors, smoking and physical activity was seen in those who received the intervention, for example mean change in HbA1c -1.32 (-1.57,-1.06) versus -0.81 (-1.02,-0.59). The significant benefits in the intervention group across 4 out of 5 health beliefs seen at 12 months were sustained at 3 years. For example, those in the intervention group report higher illness coherence compared to the control group (0.93, 95% confidence interval (CI) 0.20 to 1.65, p=0.01). At 3 years there is a trend to lower depression scores in the intervention group (-0.29, 95% CI -0.74 to 0.15, p=0.19). There are no differences between the groups for the problems areas in diabetes scale or the measures of quality of life at 3 years.
Conclusion: A one-off structured group self-management education programme for patients with newly diagnosed type 2 diabetes showed significant improvements in weight and smoking status at 12 months with sustained positive changes in a range of illness beliefs at 3 years.

Fear of hypoglycaemia: low incidence in educated patients with diabetes mellitus

V. Hartung, K. Reise, C. Kloos, N. Müller, G. Wolf, U.A. Müller;
University Hospital Jena, Department of Internal Medicine III, Germany.

Background and aims: Hypoglycaemia is the most frequent adverse effect of drug treatment of diabetes and can in worst cases cause death, either by itself or, for instance, when driving or operating heavy machinery. Hence fear of hypoglycaemia is a reasonable reaction but in which dimensions concerning ratio and intensity and what are the definite reasons? Novel contraction of diabetes and inability to handle could be the most likely assumption. Suffering from hypoglycaemia frequently in the past could be another reason. To find out exactly we studied the prevalence and intensity of fear in patients with diabetes mellitus type 1 and 2 in a German cohort.
Materials and methods: We assessed fear of hypoglycaemia (FOH) in 719 patients taking any diabetes medication (age 62.2years; time since diagnosis 16.3years; BMI 31.2kg/m²; HbA1c 7.31%) and treated at a university outpatient department using a standardised questionnaire. All patients had at least one structured education in the preceding 20 years. We used a scale from 1-6 to rate FOH (1: no fear at all; 6: extensive fear). The patients were grouped to no fear (score 1, 2) and fear (score 4-6). Score 3 was discounted to exclude indecisive or uncertain decisions. Clinical and laboratory data are drawn from the electronic patient record EMIL (http://www.itc-ms.de). HbA1c was DCCT adjusted.
Results: 118 patients (8.1%) stated to have FOH. 492 patients (68.4%) are unafraid of hypoglycaemia. Patients with FOH were more female (49.2 vs 35.8%; p=0.007), younger (58.6 vs 63.7y; p<0.001), had a higher HbA1c (7.47 vs 7.24%; p=0.026), higher overall lifetime incidence of severe hypoglycaemia (0.69 vs 0.26; p=0.005), more non-severe hypoglycaemia (0.92 vs 0.46 per week; p<0.001), a higher plasma glucose threshold for symptoms of hypoglycaemia (3.8 vs 3.5mmol/l; p=0.01), did more blood glucose self monitoring (26 vs 21 per week; p<0.001), had more insulin injections (3 vs 2 per day; p=0.006) and had predominantly diabetes type 1 (33.1 vs 19.9%; p=0.002). Furthermore patients with FOH had a lower WHO (Five) Well-Being Index (12 vs 16; p<0.001; max. score 25), an increased impairment by hypoglycaemia (4 vs 3; p<0.001; max. score 6) and more difficulties at work caused by hypoglycaemia (3 vs 1; p<0.001; max. score 6) compared to the ones with no FOH. No significant differences were observed regarding time since diagnosis (17.2 vs 16.3years), the kind of therapy differentiated into therapy with insulin and oral hypoglycaemic agents (84.4 vs 76.4%), the daily insulin dose (52.7 vs 47.1U/d), last BMI (30.9 vs 31.5kg/m²), incidence of severe hypoglycaemia during the last 12 months (0.08 vs 0.04), the social status (10 vs 11; max. score 21), when nobody was around while hypoglycaemia (46.2 vs 40.2%) or when it arose at night (46.7 vs 39.7%).
Conclusion: There are proportionally fewer patients with diabetes who suffer from noteworthy fear of hypoglycaemia. General reasons for this fear are more likely its consequences such as impairment or difficulties at work, than the conditions per se. It may also be related to a certain type of personality, based on or interrelated with a poor Well-being Index. Because the patients in this survey were a selection from a university outpatient department, it is unclear to what extent these results can be transferred to the general population in which fear could either be less frequent or even more, when, for example, less participation in educational programmes is considered.

1030

Coaching by a dietician: a cost-effective alternative to diabetes management?

P. Perron, M. Labonté, F. Jean Denis, J. Ménard, G. Houde, J.-L. Ardilouze; Endocrinology, Centre hospitalier universitaire de Sherbrooke, Canada.

Background and aims: World prevalence of diabetes and associated burden of care and complications are rising. Cost-effective management alternatives are badly needed. Cardiovascular risk (CVR) management by dieticians is one alternative worth assessing over a long term. This 3-year randomized trial aimed to show that dietician-led therapy management with an endocrinologist, for purposes of annual follow-up and advice as needed, enables recommended diabetes outcomes and is less costly than regular care.
Materials and methods: Diabetic subjects (n=101, HbA_{1c}>7%) were randomized to a Dietician-Coached Group (DCG) or a Conventional Group (CG) with follow-up as usual by endocrinologists ± general practitioners. DCG met with coach every 3 months (physical and biochemical measures, exercise, diet, smoking cessation, hypoglycaemia recording, capillary glucose monitoring and motivation), had monthly follow-up phone calls with coach and a yearly endocrinologist follow-up. Variables were measured every 3 months for DCG vs. yearly for CG.
Results: At baseline, groups (DCG n=51/CG n=50) were similar in age (60±10/60±11 yrs), duration of diabetes (16±9/16±10 yrs), systolic and diastolic BP (sBP: 131±15/131±24; dBP: 74±9/77±10 mmHg), fasting plasma glucose (FPG: 8.8±3.2/8.4±3.3 mM), HbA_{1c} (8.1±0.9/8.1±1.1%), triglycerides (1.88±1.28/1.78±1.23 mM), LDL (1.94±0.70/2.03±0.64 mM) and total cholesterol/HDL (3.39±1.16/3.50±1.27 mM). DCG subjects were heavier (BMI: 34±8/31±5 kg/m^2; p=0.03, waist circumference (WC): 113±18/106±12 cm; p=0.03). At 2 years (DCG n=39/CG n=42), ANOVA with repeated measures showed evolution between groups differed for HbA_{1c} (DCG: baseline: 8.1±0.9; 1 yr.: 7.3±0.8; 2 yrs.: 7.4±0.9% vs. CG: 8.1±1.1; 8.2±1.5; 7.8±1.1%; p≤0.001), dBP (74±9; 69±10; 69±10 vs. 77±10; 79±10; 76±9 mmHg; p=0.004), and WC (111±18; 110±18; 110±20 vs. 106±13; 108±13; 108±14 cm; p=0.015). At 2 years, DCG had an HbA_{1c} value of 0.4% lower than CG, which is clinically significant. Moreover, in DCG, the greater improvement in HbA_{1c} was observed at 1yr. vs. baseline (p≤0.001) compared to 2yrs. vs. 1yr. (p=0.08). There was no difference for BMI, FPG, microalbuminuria and lipid profile which was already on target at baseline.
Conclusion: After 2 years, diabetic patients coached by a dietician clinically improve HbA_{1c} and dBP. This simpler model of dietician coaching seems to be superior to regular care at improving diabetes outcomes and CVR factors. Should our 3-year analysis confirm our preliminary results? Cost analyses are ongoing.

Including community health workers in an effective model of diabetes self-management education

D. Fillman[1], D. Tomky[2], L. Vukovljak[1], K. Fitzner[1];
[1]American Association of Diabetes Educators, Chicago, [2]ABQ Health Partners, Albuquerque, USA.

Background and aims: 24 million people in the USA have diabetes, a costly chronic disease. Self-management education or training (DSME) is a key step in improving health outcomes and quality of life for these people. A team approach to providing DSME is described by the *Guidelines for the Practice of Diabetes Education* and is being adopted in practice. The aims of our study were to: a) define a model for DSME provided by a multi-level diabetes education team; and b) answer the question, "what are the unique roles and responsibilities of those who deliver diabetes education and care?"
Materials and methods: From 10/09-2/10, we conducted desk audits of 100 applications to the Diabetes Education Accreditation Program and examined 10 additional programs identified as having "best practices" to define the role of community health workers (CHW) in actual DSME practice and identify the education delivery models in which they worked. To be inclusive, the definition of CHWs included community health advocates, lay health advisors, lay health educators, community health representatives, tribal diabetes educators, peer health promoters, community health outreach workers, and promotores de salud. Findings from our review were compared to the National Standards for Diabetes Education and requirements put forth by the U.S. Centers for Medicare and Medicaid Services. These criteria were used to examine the strengths and weaknesses of the different approaches, roles and models identified.
Results: The review found that CHWs are frontline public health workers who are trusted members of and/or have a uniquely close understanding of the community served. CHWs can effectively serve as bridges between ethnic, cultural and geographic communities and the health care providers. There are four scenarios in which CHWs and experienced and/or credentialed diabetes educators can effectively work together. These four distinct DSME models are: 1) Shared Teaching; 2) Top Down; 3) Multi-Class at One Time; and 4) Supportive Role. In these models, the professional educator provides the clinical instruction and serves as supervisor. CHWs, who are non-professional health care providers with little expertise in DSME and/or management, support the DSME services provided to people with diabetes.
Conclusion: A DSME team approach is effective in helping people with diabetes gain the skill and knowledge necessary to change their behaviors and effectively manage their illness. Diabetes education is provided by health care professionals from many disciplines, involving practitioners with varying levels of experience/expertise in diabetes management, diabetes education, and clinical care. Moreover, DSME is most effective and sustainable when it is delivered by individuals who are prepared, competent, and function within the practice level articulated in the *Guidelines for the Practice of Diabetes Education*. Within the context of four models of DSME, and when supervised by a professional and/or credentialed diabetes educator, CHWs can effectively assist, provide important linkages to the local community, and successfully serve as part of the DSME team.

An interactive 1 hour educational programme for junior doctors delivered at their induction improves the quality of inpatient diabetes care

C.G. Taylor Jr.[1], A. Scott[1], R. Herring[2], A. Crown[3], D. Russell-Jones[2], S.R. Kottegoda[4], J. Quin[3], N. Vaughan[3], C. Morris[5], G. Rayman[1];
[1]The Diabetes Centre, Ipswich Hospital, [2]Royal Surrey County Hospital, [3]Royal Sussex County Hospital, Brighton, [4]University Hospital Lewisham, London, [5]University of Bedfordshire, United Kingdom.

Background and aims: The prevalence of diabetes amongst the inpatient population is increasing and more rapidly than that in the general population as this represents a more aged population. This has increased the management decisions having to be made by junior doctors. Unfortunately postgraduate education does not routinely address the skills needed to appropriately manage this patient group and in hospitals in the UK relatively little time is given to teaching junior doctors about diabetes care.
Materials and methods: We designed interactive teaching programmes for medical and surgical junior doctors which can be delivered in 1 hour at their induction or within scheduled teaching. These were centered on adults learning theories. Key aspects of care were covered in a case based format. Reaction to the teaching sessions was evaluated using questionnaires. Learning was evaluated by assessing the change in the rating by trainees of their confident in managing 5 key areas of care assessed before and immediately after sessions. Whether this influenced practice was assessed by auditing aspects of inpatient care in the hospitals before and 3-5 months after completing education.
Results: 174 (85%) of 206 trainees provided feedback using Likert scales of 1-5. Clarity and ease of understanding scored highly (4.5) as did the response to the question of whether the designs of the programmes increase participation (4.5). The programmes were highly recommended (4.5). The most liked aspects were interactivity (21%), the case based format (22%) and teaching design (47%). Confidence in juniors' management in five key areas of care increased significantly [from 17.4 (SD 3.9) to 24.7 (SD 2.6), p < 0.001]. Following the teaching sessions the most common key take home points and planned changes in their clinical practice were related to improved glycaemic management (24 and 25% respectively), improved insulin infusion use (22 and 26%), avoiding prescription errors (20 and 22%) and foot assessment (19 and 13%). There were statistically significant improvements in the frequency of foot assessments, appropriate insulin infusion management and prescription errors (p < 0.05).
Conclusion: We have demonstrated that a well designed teaching programme on inpatient diabetes care can be effectively delivered within 1 hour and hence easily introduced to most hospitals. The interactive design, based on learning theories and using a case based format were likely to be central to the significant changes seen in trainees confidence; more importantly in the quality of inpatient care.

1033

Improving diabetes care through multidisciplinary training: The Christian Medical College-Vellore/WDF diabetes education project

A. Joseph[1], V. Aruldas[2], R. Daniel[3], A.E.I. Pittard[4], A. Kapur[5], N. Thomas[3];
[1]Schieffelin Institute of Health Research & Leprosy Centre, Karigiri, Tamil Nadu, India, [2]Christian Medical Association of India, New Dehli, India, [3]Christian Medical College, Vellore, Tamil Nadu, India, [4]Albert Einstein College of Medicine, Bronx, USA, [5]World Diabetes Foundation, Kongens Lyngby, Denmark.

Background and aims: Diabetes is a major health care issue in India, yet doctors and nurses often have outdated information on standards of care, and foot care is underemphasized despite low rates of footwear use. We sought to improve diabetes care in rural and semi-urban areas by training doctors, nurses, foot care technicians (FCTs), and cobblers through an existing network of mission hospitals.
Materials and methods: A multidisciplinary training program was developed by the Departments of Endocrinology and Biochemistry at Christian Medical College-Vellore (CMC), the Schieffelin Institute of Health Research & Leprosy Centre (SIHRLC) and the Christian Medical Association of India (CMAI). Eligible hospitals were identified by the Dept of Endocrinology and CMAI. Each hospital was invited to send at least 1 doctor, 2 nurses, 1 FCT, and 1 cobbler to receive comprehensive training in diabetes care. Doctors were trained in a 10-day course and nurses in a 14-day course taught by professors and diabetes nurse educators from CMC's Department of Endocrinology, with support from other departments including Biochemistry, Rehabilitation and Ophthalmology. At SIHLRC, FCTs received 2 weeks of training in foot care and treatment of neuropathic foot problems, and cobblers received 1 month of training in orthopedic shoemaking. Key components of the program included emphasis on a team approach to diabetes care and the role of diabetes educators. Baseline data was collected from application forms. Evaluations were gathered for all teaching sessions. Follow-up questionnaires were sent by e-mail to all hospitals 6 months after completion of training. On-site monitoring visits were conducted for 20% of the trained hospitals.
Results: During 2004-2009, multidisciplinary training in diabetes care was provided for 100 mission hospitals in 22 states across India. At least 1 doctor was trained at 100% of hospitals, at least 1 nurse at 100%, at least 1 FCT at 58%, and at least 1 cobbler at 47%. Follow-up questionnaires were received from 36% of hospitals. Among those returning questionnaires, 89% had started diabetes clinics. There was an average of 53 new diabetes outpatients per hospital, an increase of 34% in patient capacity, by 6 months after training. Most hospitals (74%) joined CMC's laboratory quality control program. Other activities by trained hospitals included outreach clinics (25%), diabetes camps (39%), and health education (53%). These successes occurred despite significant attrition at some hospitals: trained doctors left at 17%; trained nurses at 35%; trained FCTs at 47%; and trained cobblers at 36%. Trained sites reported lack of staff as the most significant challenge they faced in providing quality diabetes care (74%), followed by the cost of care (53%) and lack of facilities (31%); difficulty procuring drugs was a relatively unimportant factor (6%).
Conclusion: Comprehensive, multidisciplinary training of doctors and nurses promotes the establishment of diabetes clinics in underserved areas and markedly increases the number of diabetic patients receiving treatment. Trainings should take attrition rates into account, and should emphasize low-cost treatment options.

Physician-patient ethnic concordance improves diabetes care for ethnic minority patients

B.R. Shah[1,2], S. Anand[3], D.G. Manuel[2,4], J.E. Hux[1,2];
[1]Department of Medicine, University of Toronto, [2]Institute for Clinical Evaluative Sciences, Toronto, , [3]McMaster University, Hamilton, [4]Ottawa Hospital Research Institute, Canada.

Background and aims: Non-White patients who receive care from physicians from the same ethnic group have greater satisfaction with care and improved health care utilisation. However, no studies have examined whether physician-patient ethnic concordance influences the quality of diabetes care, where greater cultural understanding may lead to improved dietary, physical activity and medication adherence. This study evaluated whether the quality of diabetes care for minority patients is influenced by the ethnicity of their family physicians.
Methods: Family physicians were randomly recruited from mutually exclusive neighbourhoods in the Toronto area with high concentrations of people with Chinese origins or people with South Asian origins. Recruitment was stratified by physician ethnicity. From each physician's practice, up to 10 diabetic patients with Chinese or South Asian origins were randomly selected. Diabetes quality indicators were collected by chart abstraction. The primary outcome was the last A1c achieved. Other outcomes were the last blood pressure and LDL-cholesterol achieved, and documentation in the chart of a foot examination. Within each ethnic group, outcomes were compared based on whether the physician was ethnically concordant or discordant with the patient. Generalised linear models were used to determine statistical significance, accounting for the clustered nature of the data within physician practices and adjusting for patient age, sex and diabetes duration.
Results: 45 family physicians were recruited and 416 patients were included. Most Chinese diabetic patients had Chinese family physicians. Chinese patients with Chinese family physicians achieved better glycaemic control than those with ethnically discordant family physicians. No difference in glycaemic control was seen among South Asian patients with ethnically concordant versus discordant family physicians, and no differences were seen in either group for other outcomes. There was a strong trend towards differences in foot examination rates, but because this outcome was highly clustered within physician practices, it was not statistically significant in either ethnic group.

Table: Quality of care for ethnic minority patients, stratified by physician ethnicity.

	Chinese diabetic patients			South Asian diabetic patients		
	Chinese physicians	Non-Chinese physicians	Adjusted p-value	South Asian physicians	Non-South Asian physicians	Adjusted p-value
n	148	22		129	117	
A1c	0.070±0.010	0.077±0.013	0.009	0.075±0.012	0.074±0.013	0.4
Systolic BP	129±12	128±14	0.6	130±16	127±16	0.3
Diastolic BP	76±8	78±8	0.2	76±10	79±8	0.2
LDL-cholesterol (mmol/L)	2.2±0.8	2.6±0.9	0.4	2.4±0.9	2.2±0.8	0.3
Foot examination	84%	59%	0.2	46%	57%	0.3

Conclusion: Among diabetes patients with Chinese origins, those whose family physician also had Chinese origins achieved better glycaemic control. These differences persisted even after adjusting for patient age, sex and diabetes duration. The absence of an effect in the South Asian population may be due in part to their greater linguistic and cultural heterogeneity compared to the Chinese population, or because there is greater English-language use among Canadians with South Asian origins than those with Chinese origins. The findings suggest that health care providers with better cultural understanding can influence diabetes care for patients from certain ethnic groups.

Effects of a systematic smoking cessation intervention in diabetic patients

R. Candido[1], E. Tommasi[1], G. Jagodnik[1], R. Alberti[1], B. Baskar[1], M. Stuper[1], N. Daris[1], E. Presti[1], E. Caroli[1], E. Manca[1], A. Petrucco[1], A. Vegliach[2], R. Purich[2], B. Fabris[3], R. Tominz[4];
[1]Diabetes Center, A.S.S. 1 Triestina, [2]Smokers Clinic, A.S.S. 1 Triestina, [3]Department of Clinical Medicine and Neurology, University of Trieste, [4]Department of Prevention, A.S.S. 1 Triestina, Trieste, Italy.

Background and aims: Cigarette smoking is the leading preventable cause of illness and premature death in developed countries. Several clinical studies have reported significant links between smoking and development of diabetes, micro- and macrovascular complications, and impairment of metabolic control. Although several studies have demonstrated the efficacy and cost-effectiveness of smoking cessation counseling in changing smoking behavior among the general population, the role of system-based approaches that make smoking a routine part of office contacts and provide multiple prompts, advice, assistance, and follow-up support in diabetic subjects remains to be clarified. Therefore, the aim of this study was to evaluate the effectiveness of a systematic smoking cessation intervention in diabetic patients as a routine component of diabetes care.
Materials and methods: All the afferent type 1 or type 2 diabetic patients at the Diabetes Center were systematically reviewed to confirm their smoking status. The diabetic subjects who were current smokers were considered

to be candidates for intervention. The intervention protocol consisted of: 1) assessment of dependence and motivation to stop smoking; 2) measurement of carbon monoxide concentration of expired air by smokerlyzer; 3) face-to-face interview with a nurse who was a member of the team; 4) optional nicotine replacement therapy or other smoking cessation medication; 5) follow-up support program which included a telephone call 2 and 4 weeks after the cessation date, a follow-up visit after 3-4 months and a final visit after 12 months.
Results: A total of 95 diabetic smokers were invited to participate to the intervention program and 82 (78%) agreed to take part in the study. After 6 months, 22 patients (27%) reported that they had stopped smoking and this was confirmed by measuring the carbon monoxide concentration of expired air. Among participants who continued smoking, a significant reduction was evident in the average cigarette consumption. Of the 82 patients participating to the intervention program 23% were treated with nicotine replacement therapy or varenicline and 28% were referred to smokers clinic for a more comprehensive evaluation.
Conclusion: The present study shows that a structured intervention that makes smoking a routine part of office contacts seems to be effective in inducing smoking cessation in diabetic patients, thus suggesting that a systematic intervention including smoking cessation counseling and other forms of treatment should be a routine component of diabetes care.

PS 98 Tools for improving diabetes control

1036

Design and development of a computer assisted clinical decision support system to help physicians manage patients with type 2 diabetes mellitus
D. Rodbard[1], R.A. Vigersky[2];
[1]Clinical Research and Medical Informatics, Biomedical Informatics Consultants LLC, Potomac, [2]Diabetes Institute, Walter Reed Army Medical Center, Washington, USA.

Background and aims: The increasing number of options for therapy and the failure of most patients to achieve A1C goals in a timely manner suggest the need for clinical decision support at the point of care. We sought to develop a customizable software system that could provide advice to primary care physicians at the point of care, providing recommendations and explanations.
Materials and methods: We have developed a computer-assisted decision support (CADS) system with customizable modules for patient, provider, and administrator. CADS is based on extensive statistical analysis and graphical displays of uploaded glucose data (SMBG); medication history; individualized glycemic goals; analysis of laboratory data (A1C, renal and hepatic function); and co-morbidities (cardiac, renal, hepatic, gastrointestinal). The software provides a concise report to the clinician regarding overall quality of glycemic control and identifies problems such as hypo- and hyperglycemia, excessive variability, insufficient glucose monitoring, and presence of various patterns. A rule-based expert system then makes recommendations to adjust dosage of current medications, discontinue medications, add new medications, or change the treatment regimen. We have constructed algorithms with recommended sequences for 61 regimens, including therapeutic lifestyle changes, 8 forms of monotherapy, 22 forms of dual therapy, and 30 forms of triple therapy utilizing 8 classes of medications: metformin, DPP-4 inhibitors, GLP-1 analogs, thiazolidenediones, sulfonylureas and glinides, alpha-glucosidase inhibitors, and basal insulins. Treatment pathways can be customized by the individual physician or clinic. The algorithm considers pharmacodynamics as well as relative and absolute contraindications, and offers alternatives and options. The user can override the program's recommendations and can readily access brief or detailed prescribing information, clinical practice guidelines, or the medical literature. The logic of the program can be modified using a series of tables, without the need for reprogramming.
Results: A prototype system has been constructed, tested with real and synthetic data, and found to perform well. The program analyzes SMBG data, identifies problems (hypoglycemia, hyperglycemia, variability, or insufficient glucose data) and recommends adjustment of dosages, addition or discontinuation of medications. The program provides caveats appropriate to each case. Extensive safety testing has been performed. The recommendations of the program are consistent with the judgment of highly experienced endocrinologists in a large series of test cases. The software has been integrated with a Comprehensive Diabetes Management Program that provides reminders and alerts and interfaces with an electronic medical record. The program can also operate in a stand alone mode with manual entry of laboratory data and medication history.
Conclusion: This study demonstrates that computer assisted clinical decision support is feasible. The logic of the program can be custom tailored to the preferences of individual clinics and physicians.

Acceptance and outcome of knowledge-based decision support in routine diabetes care is strongly related to HbA_{1c} at baseline
P. Augstein[1], L. Vogt[2], K.-D. Kohnert[1], P. Heinke[1], E. Salzsieder[1];
[1]Research, Institue of Diabetes, [2]Research, Diabetes Service Center Karlsburg, Karlsburg, Germany.

Background and aims: The Diabetiva© program launched 2006 by the German health insurance fund BBK Gesundheit offers continuous glucose monitoring (CGM) and decision support generated by the Karlsburg diabetes management system KADIS® to their insured diabetics. Diabetiva© is open for diabetics with cardiovascular risk and focuses on improvement of routine out-patient diabetes care according to the guidelines of the German Diabetes Association. We addressed the question, whether acceptance of decision support and metabolic outcome differs between general practitioners (GP) and diabetes specialists (DSP) involved in the Diabetiva© program.

Materials and methods: The Diabetiva© timeline includes an annual CGM followed by decision support for therapy optimization and quarterly medical check-up including HbA_{1c} detection. Patients with two CGM readings (*n*=352) were analyzed retrospectively for acceptance of the KADIS°-based decision support by the GP or DSP using a questionnaire and the outcome of the Diabetiva© program, with HbA_{1c} as primary outcome parameter.
Results: After running Diabetiva° for 36 months 799 insured diabetics (95.9% Type 2 diabetes) were enrolled and had received 1,354 CGMs. Patients were cared for by 299 GPs and 44 DSPs. 352 Patients performed already two or more CGM trails and could therefore be considered for the final outcome evaluation. For these patients approximately 74% of physicians accepted KADIS° as patient-focused support to optimize diabetes therapies; 39% used the therapeutic regimes without changes and 35 % used slight modifications. 26% of physicians did not accept KADIS°-based decision support. Logistic regression revealed that KADIS° acceptance was significantly depended on HbA1c at baseline (p<0.05). GP or DSP and type of therapy had no influence whether on acceptance nor on outcome parameters. Multiple regression analysis revealed that HbA1c and secondary outcome parameters 24 months after enrolment into Diabetiva© depend only from acceptance of KADIS° and from HbA1c at baseline (p<0.001). Again, GP or DSP type of therapy, age, onset of diabetes, BMI, and gender had no significant influence on the outcome parameters. If KADIS° was accepted HbA1c could be decreased overall by -0.38 ± 0.69% (p<0.01), whereas HbA1c at baseline <6.5% HbA1c increased by +0.05 ± 0.39% (p<0.01) abd decreased at 6.5 - 7.0% by -0.22% ± 0.49% (p< 0.01); at 7.0 to 7.5% by -0.42 ± 0.52% (p< 0.01); at 7.5 to 8.0% by -0.52 ± 0.0.44% (p<0.01); and at >8.0% by -1.31 ± 0.79%. But if KADIS°-based decision support was declined the impact of Diabetiva© was completely diminished: overall increase of HbA1c by +0.40 ± 0.77% (p<0.01).
Conclusion: Decision support is highly accepted by GPs as well as DSPs especially for diabetics with elevated HbA1c at baseline. The high acceptance rate of 74% and the significant decrease in HbA1c reveal that KADIS° in combination with CGM is an useful tool to support effectively outpatient management in routine diabetes care.

1038

Self-management support - a comparison of current practices for diabetes care in the Danish Healthcare System and Kaiser Permanente

M.L. Schiøtz[1], M. Strandberg-Larsen[2], A. Frølich[3], A. Krasnik[2], J. Bellows[4], J.K. Kristensen[5], P. Vedsted[5], P. Eskildsen[6], H. Beck-Nielsen[7], J. Hsu[8];
[1]Steno Health Promotion Centre, Steno Diabetes Centre, Gentofte, Denmark, [2]Section of Health Services Research, Institute of Public Health, Copenhagen, Denmark, [3]Copenhagen Hospital Corporation, Bispebjerg Hospital, Copenhagen, Denmark, [4]Care Management Institute, Oakland, USA, [5]Research Unit for General Practice, Aarhus, Denmark, [6]Køge Hospital, Denmark, [7]Odense University Hospital, Denmark, [8]Massachusetts General Hospital Department of Health Care Policy, Clinical Economics and Policy Analysis Program, Boston, USA.

Background and aims: Self-management support is considered an essential part of care for people with diabetes. Despite the availability of internationally-accepted treatment guidelines describing optimal management of patients with diabetes many patients do not receive such level of care and support. The aim of this study was to investigate receipt of self-management support (SMS), and self-management behaviours of patients with diabetes in two healthcare settings: Kaiser Permanente, Northern California (KPNC) and the Danish Healthcare System (DHS).
Materials and methods: Using self-administered questionnaires administered in 2006 and 2007, 1871 diabetic patients (DHS=1548 subjects, 75% response rate; KPNC=323, 61% response rate) reported on the amount of SMS received during the past year. Using logistic regression approaches, we compared the percentages of patients reporting any receipt of each type of SMS and SM behaviours.
Results: Receipt of SMS varied substantially between the two systems. Diabetic patients in KPNC more frequently reported receiving all types of SMS for their disease than did patients in DHS: among KPNC and DHS patients respectively, 85% vs. 72% (p<0.0001) discussed methods to prevent disease deterioration with their doctor; 77% vs. 58% (P<0.0001) received support to set individual disease control goals; 73% vs. 47% (P<0.0001) engaged in making plans for their treatment; 59% vs. 26% (P<0.0001) had adverse effects of the medication prescribed to them explained; and 72% vs. 62% (p<0.005) experienced shared decision making. Substantially fewer patients in both systems used tools and approaches to support SM, though more patients in KPNC reported any use compared to DHS patients: 34% vs. 11% (P<0.0001) used existing patient education programs or support groups; 38% vs. 28% (P<0.0005) used websites with information about health and illness; and 56% vs. 34% (P<0.0001) used written materials about managing their health condition. Less than half of the respondents in both systems reported that they took their diabetes medication as prescribed and followed the national guidelines for exercise.
Conclusion: While patient self-management is associated with better patient outcomes, not all patients receive support from their physicians in these efforts. We found substantial differences in the frequency of SMS received across the two health care systems. For all aspects of SMS KP performed better that the DHS. Patient self-management represents an important but under-supported area of care for those with chronic conditions. Efforts to improve SMS could help address quality concerns in both Denmark and the United States.

1039

Type 2 diabetes treatment information for patients in the Internet. Is it useful for shared decision making?

G. Gimenez-Perez, O. Simó, A. Recasens, I. Castells;
Diabetes, Endocrinology and Nutrition Unit, Hospital General de Granollers, Spain.

Internet is widely used by patients to retrieve updated health information. Consumer oriented treatment information should facilitate shared decision making between patients and health providers. The DISCERN tool has been developed and validated to evaluate quality of information about treatment choices. It scores 15 different items plus a global score from 1 (poor) to 5 (excellent). To facilitate shared decision making, uncertainty topics should be covered, and readability should be adequate.
Objective: To evaluate the quality of the information about treatment choices for type-2 diabetes available in consumer oriented websites using the DISCERN tool. To evaluate readability of consumer oriented web pages about diabetes treatments.
Materials and methods: The first thirty websites obtained from Google, Yahoo and MSN search engines using the terms "type 2 diabetes" and "treatment" were retrieved. Websites were selected by one investigator according to pre-specified inclusion and exclusion criteria. Non-selected websites were additionally reviewed by a second investigator to confirm the appropriateness of its non-selection. Selected websites were evaluated by a third investigator using the DISCERN instrument adapted to type-2 diabetes treatments. Two random samples of websites were evaluated by two additional investigators to evaluate the agreement of the evaluation between investigators using the weighted kappa statistic. Readability was evaluated using the Flesch Reading Ease and the Flesch-Kinkaid Grade Level scores obtained using a Microsoft Word processor. Additionally we evaluated the presence of any reference to the DCCT, UKPDS, ACCORD, ADVANCE and VADT studies.
Results: After the selection process 37 websites were finally evaluated. The main reason for exclusion was being retrieved in various search engines. Sixty-five percent of websites scored 3 or more in the global item indicating a moderate to excellent global information quality. More than 50% of websites scored less than 3 in the items "addressing uncertainty areas" (59%), "sources of information" (54%) and "benefits of treatments" (51%). We could not find any reference to the DCCT or UKPDS studies in 46% of websites and to the ACCORD, ADVANCE or VADT studies in 81% of them. Flesch Reading Ease was 44±13.2 (mean±SD) and Flesch-Kinkaid Grade Level 10.6±1.8 (mean±SD).
Conclusion: Although the global quality of diabetes information in the Internet seems adequate, flaws still exist in items of special interest for shared decision making about type-2 diabetes treatment choices such as uncertainty and benefits of diabetes treatments. The information available shows a tendency to more frequently cite studies with positive results instead of their counterparts. Readability scores of the evaluated websites are below the readability recommended for information addressed to the general population.

Telemedicine support using the DIABEO software on a smartphone improves HbA_{1c} in poorly controlled type 1 diabetic patients: the randomised, 6-month, multicenter TeleDiab-1 trial

P.-Y. Benhamou[1], J.-L. Bosson[2], A. Penfornis[3], D. Dardari[4], S. Franc[4], P. Schaepelynck[5], B. Catargi[6], H. Hanaire[7], L. Chaillous[8], E.M. Renard[9], J.-L. Quesada[2], S. Halimi[1], G. Charpentier[4], TeleDiab Study Group;
[1]Endocrinologie Diabétologie Nutrition, CHU de Grenoble, [2]Centre d'Investigation Clinique - INSERM, CHU de Grenoble, [3]Service de diabétologie Endocrinologie, CHU Jean Minjoz, Besancon, [4]Service diabétologie, Hôpital Sud Francilien, Corbeil Essonnes, [5]Service de Nutrition - Endocrinologie - Maladies Metaboliques, CHU Marseille Hopitaux Sud, [6]Endocrinologie Diabétologie Nutrition, Hopital Haut Leveque, Pessac, [7]Service de Diabétologie, CHU Toulouse (Rangueil), [8]Service d'endocrinologie, CHU Nantes, [9]Service des maladies endocriniennes, CHU Montpellier, France.

Background and aims: Diabeo software uploaded to a smartphone can determine the appropriate prandial insulin dose and basal adjustments for the patient, using personally tailored algorithms. Data transmission then facilitates follow-up through teleconsultations. We assessed the efficacy on HbA1c of the home use of Diabeo by chronically poorly controlled type 1 diabetic (T1D) patients.
Materials and methods: Adult patients (n=180) with T1D (> 1 year), using a basal-bolus insulin regimen (> 6 months), with HbA1c ≥ 8%, were randomized to a continuation of usual quarterly follow-up (G1), the home use of Diabeo on a smartphone suggesting insulin doses with quarterly visits (G2) or the similar use of Diabeo associated with phone calls every 2 weeks but no visit (G3) for 6 months.
Results: Six month HbA1c in G3 (8.41% ± 1.04%) was lower than in G1 (9.10% ± 1.16%; p = 0.0019). G2 displayed intermediate results (8.63 % ± 1.07%). HbA1c decreased from baseline by 0.49% ± 0.89% (p<0.001) in G2 and 0.73% ± 0.84 (p<0.001) in G3; no improvement was seen for G1 (+0.18% ± 0.93%). HbA1c improvement in G3 compared to G1 was 0.91% [0.60; 1.21] (improvement in G2: 0.67% [0.35; 0.99])). There was no difference in the frequency of hypoglycemia or in medical time spent for hospital or telephone consultations. However, patients in G1 and G2 spent nearly five hours more than G3 patients attending hospital visits.
Conclusion: The Diabeo system allows a substantial improvement in HbA1c in poorly controlled T1D patients without requiring more medical time than usual care.

Patient evaluation of education using US Diabetes Conversation Maps™ in the IDEA Study

J.M. Sperl-Hillen[1], S.J. Beaton[2], E. Parker[1], O.D. Fernandes[1], A. Von Worley[2], A.M. Hanson[1], D. Baumer[2], J. Lavin-Tompkins[1], P. Glasrud[2], C. Spain[3];
[1]HealthPartners Research Foundation, Minneapolis, [2]LCF Research, Albuquerque, [3]Merck and Co., Inc., North Wales, USA.

Background and aims: In an effort to improve self-efficacy and clinical outcomes, a new international approach to diabetes education using Conversation Maps™ (CM) has emerged. We are conducting a randomized trial to evaluate the effectiveness of this interactive, group-based learning experience using CM, which we call IDEA (Interactive Dialogue to Educate and Activate). In addition to clinical and behavioural outcomes, it is important to evaluate patient satisfaction with the experience of this novel, group-based learning method in comparison to conventional one-on-one diabetes education. The objective of this analysis is to report the data collected on the experience of patients who participated in the group and individual educational arms of the IDEA study.
Methods: 623 consented subjects with pre-existing type 2 diabetes and an A1c>=7% were randomized to group or individual education or to usual care (no education). Subjects receiving education were asked to complete a standardized evaluation regarding the subject content and the educator after each educational session. Evaluation forms contained no personally identifiable information, and included a sealable return envelope pre-addressed to the study coordinator. They were made up of likert scale questions with responses from 1-5, with 5 being the most affirmative. Overall evaluation scores were the sum of responses scaled to 100 for the content, educator, and group-specific evaluation questions. Means and standard deviations were computed for overall scores. Patient experience in each treatment arm was compared by t-tests. Relationships of demographic, psychosocial and behavioural measures with patient experience were estimated by correlations with overall evaluation scores stratified by treatment arm.
Results: Of the 489 patients attending the educational sessions, with a mean A1c of 8.2 and age 62, evaluations were collected from 87% of GE and 93% of IE participants. Both GE and IE were rated high, but overall educator ratings were slightly higher for IE, mean(SD) for GE 90.3(8.7) and IE 94.6(7.3), (p<0.0001). No significant difference was found between GE and IE for overall content ratings. No associations were found between evaluation scores and completion of the intervention in either education arm. No significant correlations were found between evaluation scores and baseline depression, self-care profiles or quality of life. Extroverted personality was weakly correlated with a more positive group experience. Diabetes empowerment was weakly correlated with favorable content and educator ratings in IE and favorable content and group experience ratings in the GE arm.
Conclusion: Overall, both education arms were perceived quite positively by patients, though IE was rated slightly higher than GE. However, higher evaluations scores were not associated with intervention completion rates. More empowered patients tended to rate both methods of education higher. Not surprisingly, extroversion was positively correlated with more positive group experiences. These findings support the opinions we heard from educators that more outgoing patients particularly liked the group experience. Forthcoming clinical, emotional, and behavioural outcomes of IDEA educational interventions will be very interesting and important.

Carelink, Skype and Facebook improve diabetes control in adolescents on pump therapy

G. Petrovski, C. Dimirovski, M. Bogoev, I. Ahmeti;
University Clinic of endocrinology, Skopje, The Former Yugoslav Republic of Macedonia.

Background and aims: To report results from Carelink, Skype and Facebook as tools to improve diabetes control in diabetic adolescents on Medtronic PRT (insulin pump with glucose sensor).
Materials and methods: A total of 38 adolescents with type 1 diabetes, ages 13-22, were randomized in to groups: Regular visits (Group 1)-as standard medical protocol with regular visits at clinic, where data was downloaded at the clinic and intervention (pump settings-basal bolus insulin, education) were given to the patient and Internet visits (Group 2)- as protocol using Carelink personal program (Medtronic Diabetes), where the data was downloaded by the patient at home and interventions (same as group 1) were given via Skype (sound and video) and Facebook (written reports and chats). A1C was obtained before, three and six months after the study.
Results: Regular visits were 11.2±1.2 patients in group 1 and Internet visits were 12.8±2.4 per patient in group 2 retrospectively. There was significantly improvement in both groups (group 1 and 2 retrospectively, 7.4 ±0.9% and 7.5±1.1% on beginning with 6.2±0.8 % and 6.3±1.0%, p<0.05). Internet visits were more preferable by the patients.
Conclusion: This brief trial suggests that adolescents with type 1 diabetes prefer to make contact with their health care providers via internet, where new technologies using specific software like Carelink, Skype and Facebook can improve diabetes control same as regular clinic visits.

PS 99 Self-monitoring of blood glucose

1043

Structured blood glucose monitoring intervention leads to significant glycaemic improvement in poorly controlled, non-insulin treated type 2 diabetes: results from the STeP study

W. Polonsky[1], L. Fisher[2], C. Schikman[3], D. Hinnen[4], C. Parkin[5], Z. Jelsovsky[6], B. Petersen[7], M. Schweitzer[7], R. Wagner[7];
[1]University of California, San Diego, [2]University of California, San Francisco, [3]NorthShore University Health System, Skokie, [4]Mid America Diabetes Associates, Wichita, [5]Health Management Resources, Inc., Carmel, [6]BioStat International, Tampa, [7]Roche Diagnostics Corporation, Indianapolis, USA.

Background and aims: While blood glucose monitoring (SMBG) is known to be beneficial among insulin users, its value and utility in insulin-naïve type 2 diabetes (T2DM) remains uncertain. The Structured Testing Protocol (STeP) study assessed the effectiveness of structured SMBG use in poorly-controlled, insulin-naïve T2DM subjects.
Materials and methods: This 1-year, prospective, cluster-randomized, multicenter, clinical trial recruited 522 poorly-controlled (HbA1c ≥7.5%), insulin-naïve T2DM subjects from 35 US primary care practices. Subjects were randomized to a structured testing protocol (STG) or active control (ACG). STG subjects used the Accu-Chek® 360° View Blood Glucose Analysis System, an easy-to-use paper tool that facilitates collection and interpretation of 7-point glucose profiles over 3 consecutive days. STG subjects completed the tool on a quarterly basis and brought it to medical visits. All STG subjects received standardized instruction in SMBG, pattern recognition and interpretation. STG physicians received an algorithm for suggested medication strategies in response to observed SMBG patterns. All STG and ACG subjects received free blood glucose meters and test strips.
Results: Intent-to-treat (ITT) analysis revealed that STG subjects evidenced significantly greater mean improvement in HbA1c than ACG subjects over the 12 months (-1.2% vs. -0.9%; Δ=-0.3%; p=0.04). Unlike previous studies, there was a high degree of protocol adherence: 70% of STG subjects who completed the study recorded ≥80% of all SMBG measurements at ≥4 of the 5 quarterly protocol visits. Per protocol analysis revealed an even greater HbA1c reduction in STG vs. ACG subjects than was seen in the ITT analysis (-1.3% vs. -0.8%; Δ=-0.5%; p<0.003). Examination of STG subjects' 7-point profiles revealed significant reductions from baseline in glucose levels at all pre- and postprandial time points (p<0.01) and in MAGE (p=0.005). Subgroup analysis of HbA1c changes over the 12 months indicated that STG subjects who reported no SMBG at baseline profited more from the intervention than those who had been previously using SMBG (-1.6% vs. -0.9%; Δ=-0.7%; p<0.0001). Similar benefits were seen among STG subjects who were taking ≤1 oral hypoglycemic agent (OHA) compared with those taking >1 OHA (-1.5% vs. -0.9%; Δ=-0.6%; p<0.0001).
Conclusion: Structured SMBG promotes significantly better glycemic control over time in non-insulin-treated T2DM when both patients and physicians collaborate in the collection, interpretation and appropriate utilization of SMBG. Approximately two-thirds of patients adhered well to the treatment protocol, suggesting that structured quarterly testing is practical as well as beneficial. Structured SMBG may be of even greater benefit in those patients with little previous history of SMBG use and among those on relatively few OHAs at baseline.

1044

Influence of glucose self-monitoring on glycaemic control in patients with type 2 diabetes mellitus

L.G. Strongin[1], A.V. Petrov[1], A.A. Kalinnikova[1], S.P. Glebov[2];
[1]Endocrinology and internal medicine of FOA, Nizhny Novgorod State Medical Academy, [2]Regional Clinical Hospital, Nizhny Novgorod, Russian Federation.

Background and aims: The aim of study is to assess if glucose monitoring patients with diabetes mellitus type 2 (DM2) is associated with better glucose control in different groups of patients being observed in primary health care settings.
Materials and methods: Data have been collected as part of mobile diabetic center program in patients with DM2 observed in primary health care. Glucose self-monitoring was assessed by questioning the patient about use of glucometer, usual frequency of glucose self-measurement and glucose levels in the week before visit. Patients measuring glucose at least once a week were referred to as performing glucose self-measurement. Glycemic control was determined by HbA1c level. Data are presented in M(SD) format, comparison of groups is done with Mann-Whitney U-criteria.
Results: 235 patients with DM2 have been examined with average age of 59(9.0) years and duration of diabetes of 9(6.7) years. 79% of patients were female. Level of HbA1c was 7.8(1.9)%. Peripheral neuropathy has been detected in 88% of patients, retinopathy in 44% and nephropathy in 53%. Treatment of diabetes included sulfonurea drugs in 52%, metformin in 63% and insulin in 31% of cases (combined use of several drugs possible). 32% of patients performed glucose self-measurement. No statistically significant difference was observed in level of HbA1c between patients with and without glucose self-monitoring (7.6(1.58) vs. 7.9(2.01)% p=0.48) as well as between those who did and did not perform measurement of postprandial glucose levels (7.6(1.63)% vs. 7.5(1.52)% p = 0.47). Among patients who were treated with insulin and with duration of insulin treatment more than 1 year HbA1c was significantly lower if they performed glucose self-measurement (8.3(1.32) vs. 9.3(2.0)% p = 0.035). Also lower HbA1c level (9.1(0.82) vs. 9.8(1.42)% p = 0.007) was present in glucose self-measurement group in patients with HbA1c>8%. Levels of glucose reported by patients correlated with HbA1c level (Spearman R = 0.59 for average glucose level, p < 0.0001).
Conclusion: Glucose self-monitoring improves effectiveness of insulin treatment in patients with DM2 if patients have some experience in using insulin. This confirms necessity of more frequent glucose monitoring in this group and can be explained by maximal flexibility of insulin therapy. Among decompensated patients with DM2 there is better glucose control in people using glucose self-measurement due to lower number of persons with severe decompensation (there were no patients with HbA1c >12% among self-measurement group while such levels were observed in several patients without self-monitoring). Here results of glucose measurement may become warning signs and motivate patients and doctors for change in treatment therefore reducing time and severity of decompensation. At the same time among patients with moderate decompensation glucose measurements may be not so convincing evidence of poor treatment and therefore do not influence level of compensation. Also there can be significant group of patients with DM2 in whom good compensation can be achieved without need for complex changes in treatment and lifestyle and in whom glucose self-measurement will not affect results of treatment. These factors explain absence of difference of HbA1c depending on glucose monitoring in patients with DM2 without marked decompensation.

1045

ACT: Actions with the CONTOUR blood glucose meter and behaviours in frequent testers

B.W. Bode[1], R.M. Bergenstal[2], R. Tamler[3], D.L. Trence[4], J. Fullam[5], P. Stenger[5],
H.C. Schachner[5], S. Pardo[5], T. Brown[3], R. Jackson[1], D. Khakpour[4], A.M. Monk[2], W.A. Fisher[6];
[1]Atlanta Diabetes Associates, Atlanta, USA, [2]International Diabetes Center, Minneapolis, USA, [3]Mount Sinai School of Medicine, New York, USA [4]University of Washington School of Medicine, Seattle, USA, [5]Bayer HealthCare Diabetes Care, Tarrytown, USA, [6]University of Western Ontario, London, Canada.

Background and aims: Self monitoring of blood glucose (SMBG) is a self-management tool for patients with diabetes. Features on blood glucose (BG) meters, such as meal markers for pre- and post-prandial BG levels and reminders for post-prandial testing, may prompt more focused self management, especially around mealtimes. This 6-month randomized, multicenter study evaluated if use of a BG meter (Bayer's CONTOUR) with meal marker + audible reminder and diabetes education maintains or increases the frequency of post-prandial testing in frequent testers compared to diabetes education and standard meter features alone. The impact of the 2 trial conditions on patients' SMBG information, motivation, and behavioral skill, and via changes in these parameters, on SMBG practice and decision-making was evaluated.
Materials and methods: Subjects (n = 211) had type 1 (n = 120) or type 2 (n = 90) diabetes, used meal-time insulin at least 1 meal per day and tested their BG levels at least 3 times per day. Subjects received diabetes education and were randomized to Basic (no meal marker or reminder) or Advanced (meal marker + reminder) and were instructed to record BG levels in their

logbook. Subjects were seen at baseline, 6 weeks, 3 months, and 6 months with no mandated actions between visits. Baseline testing frequency was self-reported, and meters were downloaded at visit 2-4.
Results: For the primary endpoint of frequency of post-prandial testing, the Advanced testing group had significantly more frequent post-prandial tests per week (Table 1) and significantly more paired pre- and post-prandial tests than the Basic group at each follow-up.

Table 1. Post-prandial Weekly Tests

	Visit 2 6 wks	Visit 3 12 wks	Visit 4 24 wks	V3-V2	V4-V3
Basic	9.2	7.9	7.1	P <0.01	P = 0.07
Advanced	13	12	10.2	P = 0.01	P = 0.001
P values (Basic vs Advanced)	<0.001	<0.001	<0.001		

Both groups had significant declines in A1c values (Basic 8.3 to 7.9 and Advanced 8.0 to 7.8). Correlation of changes in SMBG information, motivation, and behavioral skills as they relate to changes in SMBG frequency and understanding of results, as well as markers of glycemic control, including A1c, are seen in both type 1 and type 2 diabetes.
Conclusion: Current findings demonstrate that a meter with a meal marker + audible reminder increases post-prandial and paired testing.

Can glucose meters meet tighter accuracy requirements?
R. Ng[1], J. Lock[2];
[1]Abbott Diabetes Care, Alameda, [2]Internal Medicine and Endocrinology, Worcester, USA.

Background and aims: The ISO Standard (ISO 15197:2003) and various CLSI guidelines are undergoing revisions that are likely to result in tightening the accuracy requirements on blood glucose monitoring systems (BGMS). We evaluated four of the latest generation of BGMS to assess the potential impact of tighter criteria on system accuracy.
Materials and methods: The following 4 BGMS, each with 3 lots of strips, were evaluated for finger blood testing at a clinic: Bayer Contour®, LifeScan OneTouch® Ultra®2 (with the new OneTouch Ultra Blue test strip), Roche Accu-Chek® Aviva and Abbott FreeStyle Freedom Lite® system (with the new GDH-FAD test strip). A total of 150 diabetic subjects were included in the study. A trained operator tested the subject's fingertip blood in duplicate with the 4 systems and 2 YSI glucose analyzers, which served as the reference. The order of testing the 4 systems was rotated after each subject. To ensure sufficient number of finger blood samples with glucose concentrations below 2.8 mmol/L (50 mg/dL) and above 22.2 mmol/L (400 mg/dL) were tested, 8 samples were modified to lower the glucose concentration below 2.8 mmol/L (50 mg/dL) and another eight samples were modified to elevate above 22.2 mmol/L (400 mg/dL). The accuracy of the YSI analyzers was validated by testing the National Institute of Standards and Technology (NIST) Standard Reference Material SRM 965b. All systems and supplies were stored, handled and operated according to the manufacturer's instructions.
Results: The blood glucose concentrations of the 150 subjects and the 16 modified samples ranged from 1.3 - 25.5 mmol/L (23 to 460 mg/dL), with a mean value of 9.7 mmol/L (175 mg/dL) and a median of 8.6 mmol/L (155 mg/dL). The hematocrits of the 150 subjects ranged from 32% to 54% (mean and median, 42%), and were within the product specifications. A total of 331 to 332 tests were performed on each BGMS with 166 blood samples from 150 patients. All 4 BGMS met the minimum acceptable accuracy required by ISO 15197:2003, with ≥95% of the individual glucose results falling within ±20% of the reference, and within ±0.83 mmol/L (15 mg/dL) at glucose concentrations <4.2 mmol/L (<75 mg/dL)**. When the accuracy criterion was tightened to ±15% of the reference, and within ±0.83 mmol/L (15 mg/dL) at glucose concentrations <5.6 mmol/L (<100 mg/dL)*, less than 95% of the Bayer Contour results met criterion. When the accuracy criterion was tightened to ±10% of the reference, and within ±0.56 mmol/L (10 mg/dL) at glucose concentrations <5.6 mmol/L (<100 mg/dL)*, less than 95% of the Bayer Contour, LifeScan OneTouch Ultra2 and Roche Accu-Chek Aviva results met criterion; only the Abbott FreeStyle Freedom Lite system met this criterion.

System	Within ±5% or ±0.28 mmol/L (±5 mg/dL)*	Within ±10% or ±0.56 mmol/L (±10 mg/dL)*	Within ±15% or ±0.83 mmol/L (±15 mg/dL)*	Within ±20% or ±0.83 mmol/L (±15 mg/dL)**
FreeStyle Freedom Lite	72.3%	95.5%	99.7%	100%
Accu-Chek Aviva	60.5%	91.9%	99.1%	100%
OneTouch Ultra2	49.2%	80.4%	95.2%	97.0%
Contour	27.2%	59.5%	85.8%	97.3%

Conclusion: Not all BGMS can meet tighter accuracy criteria. Manufacturers will need to be vigilant in improving the accuracy performance of their BGMS to be ready for the anticipated changes in accuracy standards and guidelines.

1047

Glucose self-measurement results and life quality in patients with type 2 diabetes mellitus
A.V. Petrov[1], L.G. Strongin[1], A.A. Kalinnikova[1], S.P. Glebov[2];
[1]Endocrinology and internal medicine of FOA, Nizhny Novgorod State Medical Academy, [2]Regional clinical hospital, Nizhny Novgorod, Russian Federation.

Background and aims: Health-related quality of life (HRQL) can be differently influenced by self-measurement of glucose in patients with diabetes mellitus type 2 (DM2). Improved HRQL can be expected if it improves glucose control and is associated with reduction in diabetes complication. At the same time results of glucose measurement can become additional stress-factors if patient is decompensated and is not able to improve disease control due to lack of knowledge, training or support. Aim of current study was to assess whether patients performing glucose self-measurement are different in life quality compared to these who are not and to evaluate association between results of glucose measurement and indicators of HRQL.
Materials and methods: HRQL was assessed with use of SF-12 v.2 questionnaire in patients with DM2 referred for examination in mobile diabetic center in local areas of region by internists and endocrinologists in primary healthcare. Patients have been asked about use of glucometers and if present - about usual frequency of glucose measurement and levels of glucose during a week before visit. These who checked glucose levels at least once a week were referred to as performing glucose self-measurement. Maximal, minimal and average glucose levels have been used for further assessment. HbA1c level was measured at the visit for evaluation of glycemic control. Data are presented in M(SD) format unless specified otherwise. Mann-Whitney U-criteria has been used for comparison of groups and Spearman R-criteria to find out correlations.
Results: Data were received about 104 patients whose average age was 56(9.2) years and diabetes duration 8(6.2) years. 84% of patients were female. 39% of patients received insulin with average insulin treatment duration of 5(3.0) years. Patients who did and did not perform glucose self-measurement had statistically significant differences only on role-physical scale of questionnaire (45(24) vs. 55(26) p = 0.025) with patients performing glucose monitoring having poorer life quality. Patients with HbA1c below 7% had better HRQL in physical functioning (51(32) vs. 38(33) p = 0.045), role physical scale (54(25) vs. 44(26) p = 0.044), social functioning (67(25) vs. 56(27) p = 0.048) and role emotional scale of SF-12 questionnaire (61(23) vs. 50(24) p = 0.013). In correlation analysis there was significant although weak negative correlation between glucose levels in self-measurement and physical functioning, role physical and bodily pain scales (R = -0.27 -0.31 and -0.25 with p = 0.02 0.012 and 0.035 correspondingly).
Conclusion: HRQL was significantly lower in patients with decompensated diabetes. This can be a result of hyperglycemia symptoms or development of diabetes complications in this group. Life quality was not convincingly connected with presence of glucose self-measurement. In patients who performed glucose self-measurement it worsened together with increase in glucose levels for aspects of physical health and pain. Symptoms of hyperglycemia and diabetes complications may also play a role here but psychological perception of high glucose levels is not to be forgotten. Many diabetic patients do complain that poor results of glucose by self-measurement worsen their psychological status and this may affect results of HRQL evaluation.

Association between HbA_{1c} and self-monitoring blood glucose values in patients with type 2 diabetes

K. Kyriakopoulos[1], S. Liatis[2], K. Makrilakis[2], A. Papazafeiropoulou[3], C. Fytili[2], I. Tombrou[2], I. Vasileiou[2], A. Sotiropoulos[3], S. Pappas[3], N. Katsilambros[2];
[1]Diabetes outpatient Clinic, Ika Vyronas, Athens, [2]First Department of Propaedeutic Medicine, Athens University Medical School, [3]Diabetes Center, Nikaia General Hospital, Piraeus, Greece.

Background and aims: The role of self-monitoring of blood glucose (SMBG) in Type 2 diabetes (T2D) management is not adequately established. Aim of the present study was to assess the relationship between HbA_{1c} and SMBG values in T2D patients, as well as determine SMBG values that define a satisfactory glycaemic control.
Materials and methods: A total of 1,000 consecutive T2D patients were examined in 3 outpatient Diabetes centers. SMBG values of the previous week were recorded as well as the HbA_{1c} value at the index visit.
Results: A total of 926 patients reported they were performing SMBG at home, of which 872 had pre-prandial values and 774 also post-prandial values in their records. A very strong correlation was found between HbA_{1c} and both pre-prandial and post-prandial SMBG values ($r=0.649$, $p<0.001$ and $r=0.641$, $p<0.001$, respectively). The correlation between HbA_{1c} and the total SMBG values (both pre-prandial and post-prandial) was even stronger ($r=0.706$, $p<0.001$). In a multivariate analysis, pre- and post-prandial SMBG values had an independent association with HbA_{1c}. According to these associations, the target value of HbA_{1c}=7.0% corresponded to a mean pre-prandial SMBG value of 120 mg/dl and to a mean 2-hour post-prandial SMBG value of 151 mg/dl.
Conclusion: In patients with T2D, SMBG values for 1 week satisfactorily define glycaemic control. Post-prandial values offer additional data for assessing diabetic control. Pre-prandial values <120 mg/dl and 2-hour post-prandial values <151 mg/dl correspond to HbA_{1c} values <7.0%.

1049

Structured blood glucose monitoring reduces distress and depression, and enhances well-being in poorly controlled, non-insulin treated type 2 diabetes: results from the STeP Study

L. Fisher[1], W. Polonsky[2], C. Parkin[3], Z. Jelsovsky[4], M. Schweitzer[5], R. Wagner[5];
[1]University of California, San Francisco, [2]University of California, San Diego, [3]Health Management Resources, Inc., Carmel, [4]BioStat International, Tampa, [5]Roche Diagnostics Corporation, Indianapolis, USA.

Background and aims: Recent reports have suggested that the promotion of SMBG among non-insulin treated patients with T2DM is associated with more depressive symptoms. In the Structured Testing Protocol (STeP) study, we investigated the impact of a structured SMBG intervention on diabetes distress, clinical depression and well-being over 12 months.
Materials and methods: In this prospective, cluster-randomized, multi-centered clinical trial with 522 randomly assigned, poorly-controlled (HbA1c ≥7.5%), insulin-naïve T2DM patients, we showed that patients in a structured testing SMBG group (STG) displayed larger reductions in HbA1c over 12 months than patients in an active control group (ACG). STG subjects used the Accu-Chek® 360° View Blood Glucose Analysis System, an easy-to-use paper tool that facilitates collection and interpretation of 7-point glucose profiles over 3 consecutive days. STG subjects completed the tool on a quarterly basis and brought it to medical visits. All STG subjects received standardized instruction in SMBG, pattern recognition and interpretation. STG physicians received an algorithm for suggested medication strategies in response to observed SMBG patterns. All STG and ACG subjects received free blood glucose meters and test strips. At baseline, 3, 6, 9 and 12 months, all subjects completed self-report measures to assess diabetes-specific distress (the Diabetes Distress Scale, DDS), clinical depression (the Patient Health Questionnaire 8, PHQ8), and positive well-being (the WHO5).
Results: Intent-to-treat (ITT) analyses indicated significant reductions from baseline in DDS ($p<0.001$) and PHQ8 ($p<0.001$) scores and significant increases in positive well-being (PWB) scores ($p<0.001$) for subjects in both STG and ACG at 3, 6, 9 and 12 months. STG patients who reached criteria for significant diabetes distress (mean item DDS score ≥3) and STG subjects who reached criteria for clinical depression (total PHQ8 ≥10) at baseline showed a significantly greater reduction in distress and depression over time than ACG subjects at 9 and 12 months ($p<0.03$ in both cases) No between-group differences were found for PWB over time.
Conclusion: Contrary to previous reports and using well-validated measures, we found that both treatment groups experienced significant reductions in diabetes distress and depression and increased PWB over time. Furthermore, among patients with elevated diabetes distress or clinical depression at baseline, the structured SMBG intervention was associated with significantly greater improvement in these conditions over time than for control subjects. In sum, these findings suggest that when both patients and physicians collaborate to gather, interpret and appropriately utilize structured SMBG data, emotional distress is alleviated, not worsened.

1050

An information-motivation-behavioural skills analysis in frequent testers

T. Kohut[1], P. Stenger[2], H.C. Schachner[3], J. Fullam[3], S. Pardo[3], R.M. Bergenstal[4], B.W. Bode[5], R. Tamler[6], D.L. Trence[7], W.A. Fisher[1];
[1]Department of Psychology, University of Western Ontario, London, ON, Canada, [2]Medical Communications, Bayer HealthCare, Diabetes Care, Tarrytown, USA, [3]Medical Affairs, Bayer HealthCare, Diabetes Care, Tarrytown, USA, [4]International Diabetes Center, Minneapolis, USA, [5]Atlanta Diabetes Associates USA, [6]Department of Endocrinology, Diabetes and Metabolism, Mount Sinai Medical Center, New York, USA, [7]Department of Endocrinology and Diabetes, University of Washington Medical Center, Seattle, USA.

Background and aims: Self monitoring of blood glucose (SMBG) is a behavioral tool for patients with diabetes. Features on blood glucose (BG) meters, such as meal markers for pre- and post-prandial BG levels and reminders for post-prandial testing, may better inform self-management decisions, especially around mealtimes. This 6 month randomized, multicenter study evaluated if use of a BG meter with meal marker + audible reminder and diabetes education maintains or increases frequency of postprandial testing in frequent testers compared to diabetes education and standard meter features alone. The impact of the two trial conditions on patients' SMBG information, motivation and behavioral skills on SMBG practice and decision-making, were evaluated from baseline to completion via an IMB survey. Clinical parameters reported previously. IMB correlation to clinical parameters are presented here.
Materials and methods: Subjects (n=211) had type 1 (n=120) or type 2 (n=90) diabetes, used meal time insulin at least 1 meal/day and tested their BG levels at least 3x/day. All subjects received diabetes education and were randomized to *Basic* (no meal marker or reminder) or *Advanced* (meal marker + reminder) and instructed to record BG levels in their logbook. Subjects were seen at baseline, 6 weeks, 3 months, and 6 months with no mandated actions between visits.
Results: Baseline A1c correlated with motivation at baseline and across the study, most strongly in the type 1 population ($r= -0.24$, $p<0.01$ Visit 1; $r= -0.22$, $p<0.05$ Visit 4). In patients with type 2, increased information correlated with increased Glycomark, a reported measure of improved post-prandial glucose control ($r=0.32$, $p<0.007$ Visit 1: $r=0.38$, $p< 0.003$ Visit 4). At completion, the Advanced group had stronger understanding and belief that food and/or exercise have an effect on BG levels and were less anxious about blood sugar testing compared to subjects who did not use this feature. In subjects with type 1 and type 2 diabetes, using the meal marker resulted in significant increase in post-prandial testing (15% Visit 1 to 50% Visit 4) as well as significant improvement in understanding pre- and post-meal results over time (33% at time 1 to 72% at time 4).
Conclusion: SMBG can be an effective self-management tool that may be instrumental in achieving glycemic control among adults with type 1 and type 2 diabetes. Understanding and utilization of particular meter features may improve the value of SMBG. Correlation of changes in SMBG information, motivation, behavioral skills as they relate to changes in SMBG frequency and understanding of results, as well as markers of glycemic control, including A1c, are seen in both type 1 and type 2 diabetes.

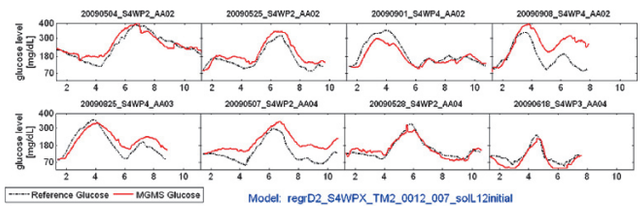
PS 100 Continuous glucose monitoring systems: devices, practice and outcomes

1051

Prospective data evaluation of the application of a multisensor device for non invasive continuous glucose monitoring

M.S. Talary[1], M. Mueller[1], O. De Feo[1], P. Zakharov[1], A. Megej[1], M. Donath[2], J. Klisic[1], W.A. Stahel[3], A. Caduff[1];
[1]R&D, Solianis Monitoring, [2]Division of Endocrinology and Diabetes, University Hospital Zurich, [3]Seminar for Statistics, ETH Zurich, Switzerland.

Background and aims: We have previously reported about the findings in clinical-experimental studies with a novel Multisensor system for non invasive continuous glucose monitoring. The Multisensor measures skin impedance and optical skin characteristics in several frequency bands of the electromagnetic spectrum as well as temperature, acceleration and humidity. In this study a Multisensor version with fully integrated sensors and battery in a miniaturised housing (54 x 65 x 13 mm) was experimentally tested to compare the outcome to previous findings using earlier versions.
Materials and methods: Six T1DM patients (age 44±16 y; BMI 24.1±1.3 kg/m2, duration of diabetes 27±12 y; HbA1c 7.3±1.0%) wore the same Multisensor at the upper arm. In total these patients performed 45 in-clinic study days; each patient performed on average seven study days (min. 5 and max. 10 days). A study day lasted approximately 10 hrs (min. 8 and max. 11 hrs) and glucose changes were induced by the administration of an oral or i.v. glucose solution. Blood glucose was measured for reference using a HemoCue analyser. Several prospective data evaluation routines were applied. The first 22 study day's data spanning all subjects were used to train a linear regression model. The global model derived was then prospectively applied to the data of the remaining 23 study days allowing for external validation. One initial baseline adjustment at the very beginning of each study day was used to adjust the level of the glucose estimate.
Results: Figure 1 shows the time series of all 23 externally validated study days. These profiles were obtained with fully prospective data evaluation using a global model with one initial calibration point. When comparing the estimated glucose to the blood glucose reference values, the model yielded a Mean Absolute Relative Difference (MARD) of 40.8%, a Mean Absolute Difference (MAD) of 51.9 mg/dL, and an R2 of 0.70 on average per study day. The Clarke error grid analyses showed 89.0% of paired glucose values in A+B, 4.5% in C, 4.6% in D and 1.9% in the E region.
Conclusion: This work demonstrates that glucose variations under controlled conditions can be monitored non invasively by a prospectively applied multiple regression statistical model. The findings from this study indicate that further development steps in the Multisensor system should not affect the estimation performance. In this respect, the expected model performance can be more reliably judged at the stage of clinical validation.



1052

Simultaneous non invasive continuous glucose monitoring on the left and right arm using two multisensor devices

A. Caduff[1], M. Mueller[1], O. De Feo[1], P. Zakharov[1], A. Megej[1], M. Donath[2], J. Klisic[1], W.A. Stahel[3], M.S. Talary[1];
[1]R&D, Solianis Monitoring, Zurich, [2]Division of Endocrinology and Diabetes, University Hospital Zurich, [3]Seminar for Statistics, ETH Zurich, Switzerland.

Background and aims: We have previously reported about the findings in clinical-experimental studies with a novel Multisensor system for non invasive continuous glucose monitoring. The Multisensor measures skin impedance and optical skin characteristics in several frequency bands of the electromagnetic spectrum. In this study a Multisensor version with fully integrated sensors and battery in a miniaturised housing (54 x 65 x 13 mm) was experimentally tested, investigating location related measurement characteristics.
Materials and methods: Four T1DM patients (age 43±9 y; BMI 24.5±3.7 kg/m^2, duration of diabetes 22±11 y; HbA1c 7.7±0.5%) performed 4 in-clinic study days with a Multisensor attached to the left and right upper arm. As a result, 32 datasets from 16 study days were obtained. The Multisensors were exchanged between the patients and the left and right arm according to a Graeco-Latin Square. Glycaemia was varied using 4 different glucose profiles. For each study day, one of the four different glucose profiles was induced via oral Carbohydrate loads. Blood glucose was measured for reference using a HemoCue analyser. Different data evaluation routines were applied to the Multisensor data in order to obtain global (identical coefficients) and personal (personal coefficients) models that were used for cross validation.
Results: Figure 1 shows all 32 glucose profiles obtained during the 16 study days, using the global model with a prospective initial baseline calibration (CEG A 44.9, B 48.0, C 3.6, D 3.0, E 0.5%). The following performance metrics was obtained from the different models. In each model an initial baseline calibration was used at the beginning of each study day (IB) as well as a full day baseline calibration (FB), with Average R2 = coefficient of determination on average over the study days, MAD= Mean Absolute Difference [mg/dL], MARD= Mean Absolute Relative Difference [%]. Global IB: 0.76, 47, 32.3; Global FB: 0.75, 29.9, 21.3; Personal IB: 0.85, 43.3, 30.7; Personal FB: 0.84, 24.1, 17.6.
Conclusion: The glucose time courses estimated by the Multisensors from the two arms are repeatably comparable, even with a global model with one initial baseline calibration only. This indicates that the sensor signal characteristics are robust enough to allow changing from one arm to the other using the same device settings and calibration. That represents thus a further indication that the Multisensor approach for non invasive glucose monitoring under such conditions is possible. It is also an indication that a personal model may be able to track glucose more accurately than a global model.

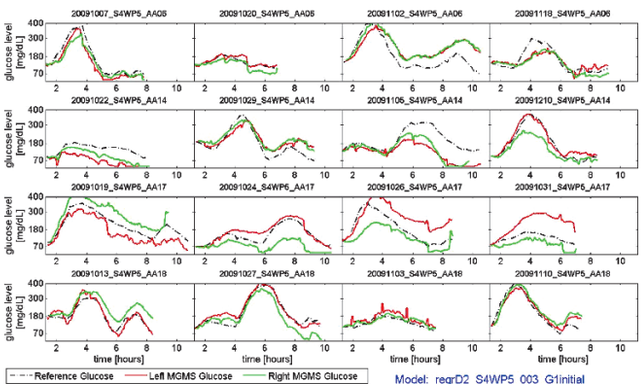


Figure 1: Overview of all 32 predicted glucose profiles with a fully prospective data evaluation of the two Multisensor devices on the left (red) and right (green) arm using a global model with one initial calibration point (Global IB).

1053

Measuring within-patient glycaemic variability: a best practice

L. Kerr, C.R. Heilmann, C. Jones, J.A. Jackson, S. Jacober;
Eli Lilly and Company, Indianapolis, USA.

Background and aims: The role of glycaemic variability (GV) in the development of diabetes complications and hypoglycaemia in patients (pts) with diabetes remains controversial. Our aim was to compare current GV measures through simulated self-monitored blood glucose (SMBG) and continuous glucose monitoring (CGM) data points to determine which measure carries the highest statistical power and effect size.
Materials and methods: We simulated datasets for 1,000 trials with pts with type 1 (20%) and type 2 (80%) diabetes. Three days of 7-point SMBG profiles (n=240 pts/trial) and 288-point CGM profiles (n=20/trial) were generated using a gamma distribution which created two patient groups, Groups 1 and 2. To assess the effect of different GV measures independent of mean BG, both groups had a mean BG of 7.94 mmol/L. GV (defined as velocity of BG change over time [mmol/L per minute]) for Group 2 ("BG Change") was 50%

greater than for Group 1 ("Reference"). Patients were randomised to diabetes type, then mealtime pattern (3 meals a day ± snack ± dawn phenomenon) and meal start time, which varied by patient-day, were also randomised. Groups were compared using a t-test for each measure. Power was calculated as the proportion of trials with a p-value <0.05. Effect size (estimate of the measure's strength to detect the difference in GV between Groups 1 and 2) was calculated by averaging the difference between groups (Group 2 - Group 1) divided by the standard deviation for the pooled groups. A Pearson's matrix was obtained for total [SD], within-day and day-to-day measures to further characterise them.

Results: See table.

Results for total GV for all measures (only SD results shown) were similar to within-day GV results. For SMBG within-day GV, SD had the highest power and effect size and for SMBG day-to-day GV, ADRR had the highest power and effect size. For CGM within-day GV, ACM had the highest power and effect size and for CGM day-to-day GV, ADRR had the highest power and effect size. For total GV, SD resulted in 100% power for both SBGM and CGM and a 2.19 and 3.14 mmol/L effect size for SMBG and CGM, respectively. For SMBG within-day, all measures correlated with each other (rho > 0.59). For SMBG day-to-day measures, CONGA and MODD highly correlated (rho = 0.73). For CGM within-day, all measures (except ARC and SD[ARC]) highly correlated with each other (rho > 0.81). For CGM day-to-day measures, ADRR, CONGA, and MODD highly correlated (rho > 0.75).

Conclusions: Effect size helped differentiate measures, and the lower power for CGM suggests more pts per trial are needed. For analysing SMBG and CGM within-patient GV data, SD is recommended for within-day and ADRR for day-to-day GV. Although ACM had a slightly higher effect size and Range and IQR had a similar effect size for CGM within-day GV, SD is preferred because it is consistent with the SMBG results. Because within-day (SMBG) and day-to-day (SMBG, CGM) measures are highly correlated, using only SD (within-day) and ADRR (day-to-day) to measure GV is currently justified.

	SMBG		CGM	
Measure	Power (%)	Effect Size	Power (%)	Effect Size
SD (mmol/L)				
Total	100	2.19	100	3.14
Within-Day	100	2.20	100	3.14
Day-to-Day	93.2	0.33	76.6	0.14

Assessment of the variance of the ambulatory glucose profile over 3 to 20 days of continuous glucose monitoring

T.C. Dunn, N. Crouther;
Abbott Diabetes Care, Alameda, USA.

Background and aims: The Ambulatory Glucose Profile (AGP) has been proposed as an effective way to identify trends in glucose abnormalities in people with diabetes using continuous glucose monitoring (CGM). The aim of this study was to evaluate the minimum number of days of CGM needed to arrive at stable glucose patterns revealed by AGP analysis.

Materials and methods: AGP analysis was performed utilizing 67 adult subjects (T1DM = 47, T2DM = 20) who participated in a study that began with 20 days of masked CGM, using the FreeStyle Navigator® System. Subjects were not able to see their CGM glucose values or trends and did not have glucose threshold or projected alarms available. Only masked data were evaluated in order to minimize effects of therapy adjustments on the evaluation. Statistics for each of 3 to 19 days of CGM data were compared to the 20-day values and evaluated on a per-subject basis. For overall summary statistics (mean, standard deviation, 10th, 25th, 50th, 75th, 90th percentiles, inter-quartile range, mean change in the hourly median curve), equivalence criteria of 90-110% of the 20-day value were evaluated. For overall rates of glucose above, below or within the target of 3.89-7.78 mmol/L (70-140 mg/dL), the absolute difference compared to the 20-day value was evaluated at equivalence criteria (based on scaling the standard error of the overall mean) of 6.40%, 1.45%, and 5.46%, respectively. For hourly AGP percentile lines (10th, 25th, 50th, 75th, 90th) the mean absolute relative difference compared to the corresponding 20-day line was calculated and evaluated against the equivalence criteria <10%.

Results: A summary of the 20-day statistics and the relationship between the number of days needed for an AGP statistic to meet the equivalence criteria for 70%, 80% and 90% of subjects is shown in Table 1. After 10 days, the glucose mean, standard deviation, 50th, 75th, and 90th percentiles are within 10% of the 20-day value for more than 80% of subjects. After 14 days, the rates of above, below and within target, the 10th and 25th percentiles, and the hourly AGP percentile lines met the equivalence criteria for over 80% of patients. The interquartile range and mean change in the hourly median curve needed more days of CGM to approximate the 20-day value for 80% of subjects: 15 and 18 days, respectively.

Conclusion: AGP analysis promises to be an effective tool for identifying glucose abnormalities and may allow the use of evidence-based and protocol-driven medical practices to select appropriate therapies to address those abnormalities. Clinical evidence is lacking to support the assumption used in this study that AGP analysis of 20 days of CGM can identify clinically important glucose trends and patterns. Within that context, however, this analysis suggests that a minimum of 14 days of CGM provides identification of individual glucose patterns. Prospective studies are needed to provide clinical evidence establishing the benefits of identifying patterns with AGP analsyis that affect treatment and improve outcomes.

Table 1. Summary of 20-day AGP statistics and number of CGM days needed to reach equivalence.

Ambulatory Glucose Profile Statistic	Mean (SD) [Min, Max] of 20-day Values for Subjects	Criteria for Equivalence with 20-day Statistic	Number of Days for % of Subjects to Meet Equivalence Criteria		
			70%	80%	90%
Mean	9.6 (1.8) [6.3, 13.6] mmol/L	ARD < 10%	6	9	11
Standard Deviation	3.4 (0.8) [1.9, 5.4] mmol/L	ARD < 10%	8	10	15

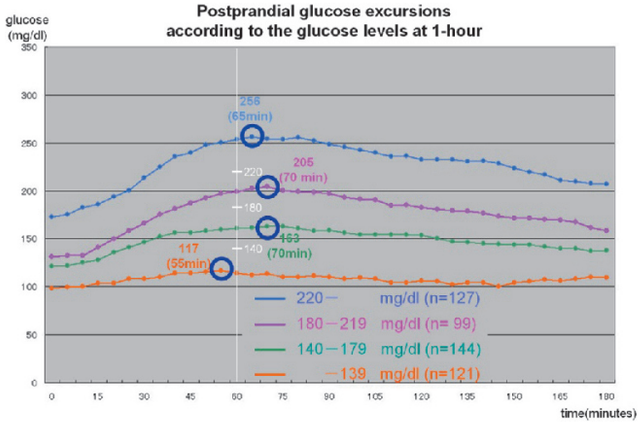
Assessment of postprandial glucose control; a consideration from continuous glucose monitoring

T. Tsuchita, S. Nagasaka, N. Takahashi, D. Sekizawa, I. Kusaka, N. Saito, H. Yagyu, S. Ishibashi;
Endocrinology and Metabolism, Jichi Medical University, Shimotsuke-city, Japan.

Background and aims: Importance of postprandial glucose control has been appreciated, although the consensus on its assessment is not established. This study was undertaken to reveal characteristics of postprandial glucose control and make a consideration on its assessment.
Materials and methods: Glucose levels until 3-hrs postprandial were measured with Continuous Glucose Monitor (CGM) in a total of 491 meals. These were obtained from a total of 103 diabetic patients (41 with type 1, 56 with type 2, and 6 with other types; with ages of 52.6±13.7years, BMI 23.0±3.9kg/m2, and HbA1c 9.1±2.2%, mean±SD). Eighty-one patients were treated with insulin (mostly with multiple injections or CSII), 11 with oral hypoglycemic agents, and 11 with diet therapy alone. Most of the patients were admitted and given controlled diet comprising 50% of energy intake as carbohydrate.
Results: Median glucose levels of the 491 meals were 126 (pre-prandial), 155 (at 30 min postprandial), 175 (at 60), 172 (at 90), 166 (at 120), 156 (at 150), and 149 mg/dl (at 180), respectively. Maximal median value was 176 mg/dl at 65 min. Pre-prandial and maximal postprandial glucose levels after breakfast, lunch, and supper were 130 and 191 (at 60), 127 and 163 (at 75), 135 and 186 (at 80), respectively. Postprandial glucose levels 45~130 min after lunch were significantly lower than those after breakfast and supper, suggesting presence of second meal effect. Between patients with or without insulin therapy, glucose excursions after meal were essentially analogous and both glucose peaks were at around 60 min. When the subjects were divided into 4 groups according to pre-prandial glucose levels (-109, 110-129, 130-159, and 160- mg/dl), corresponding maximal postprandial glucose levels were 150 (at 95), 165 (at 75), 183 (at 80), and 232 mg/dl (at 60), respectively. There was a trend that a glucose peak appears earlier as pre-prandial glucose levels increase. When the subjects were divided into 4 groups according to glucose levels at 2-hours postprandial (-140, 140-179, 180-219, and 220- mg/dl), corresponding maximal postprandial glucose levels were 133 (at 45), 173 (at 65), 205 (at 65), and 262 mg/dl (at 105), respectively. There was a trend that a glucose peak appears later as 2-hours postprandial glucose levels increase. Then we divided the subjects into 4 groups according to glucose levels at 1-hour postprandial by using the same criteria at 2-hours. Corresponding maximal postprandial glucose levels were 117 (at 55), 163 (at 70), 205 (at 70), and 256 mg/dl (at 65), respectively. The glucose peaks were observed at around 60 min, irrespective of glucose control (Figure).
Conclusion: When postprandial glucose levels are assessed at 2-hours, "real" glucose peaks are observed at 45~105 min depending on glucose control. Given the glucose spike plays an important role on vascular complications, assessment at 1-hour would be appreciated since the glucose peaks are captured at this point irrespective of glucose control.



1056

Predictors of continuous glucose monitoring (CGM) variability and associations with patient satisfaction and health perceptions in insulin-treated diabetes

D.C. Simonson[1], M.A. Testa[2], J. Gill[3], R.R. Turner[4], L. Blonde[5];
[1]Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital, Boston, [2]Biostatistics, Harvard School of Public Health, Boston, [3]sanofi-aventis, Bridgewater, [4]Phase V Technologies, Wellesley, [5]Endocrinology, Ochsner Medical Center, New Orleans, USA.

Background and aims: Glycemic variability is typically estimated using 7-point glucose profiles, which might not be sensitive to clinical predictors and patient-centered health outcomes. We modeled continuous glucose monitor (CGM) variability to determine if insulin regimen, type of diabetes, age, sex, BMI and HbA1c predict CGM within-day standard deviations (SD), and if SD changes are associated with patient satisfaction (PS) and perceived health (PH).
Materials and methods: We analyzed CGM data from 306 insulin-treated T2DM and 82 T1DM (47% male, age 54±11 yrs, HbA1c 7.8±0.7%) who were randomized to open-label daily insulin glargine + premeal glulisine (GG; n=192) or BID analogue premix 75/25 or 70/30 (PM; n=196) for 12 wks (P1), and then crossed over to the alternate treatment for 12 wks (P2). Patients were contacted weekly to ensure compliance with a titration algorithm with a target HbA1c < 7.0%. Three-day CGM and HbA1c were obtained at Wks 0, 12 and 24. Patients completed clinic-based PS and PH questionnaires at Wks 0, 8, 12, 20 and 24. CGM estimates were obtained for each patient from the 3-day session (288 glucoses/day), and regression used to model independent variables. PS was represented by the net benefit composite scale, which included 4 subscales of advocacy, general satisfaction, glycemic effectiveness and preference. The PH scale included 3 subscales of health status, vitality and sleep quality.
Results: During P1, reductions from baseline for glycemic measures were larger for GG vs PM (*p<0.001; see Table), except for % time < 3.9 mmol/l. P2 cross-over results (not shown) were similar to the between-group differences in P1. Baseline-adjusted PS (60.5±1.2 vs 45.4±1.2) and PH (427±3 vs 418±3) were higher for GG compared to PM during P1 and P2 (both p<0.01). CGM SD decreased with GG (-0.1±0.06 mmol/l, p=0.037), increased with T1DM (0.6±0.09 mmol/l), decreased by 0.02±0.004 and 0.01±0.003 mmol/l per unit increase in BMI and age, and increased by 0.4±0.04 mmol/l per unit increase in HbA1c (all p<0.001). Sex was not a significant predictor of CGM SD. The % time < 3.9 mmol/l was higher by 6.8±1.0% for T1DM vs T2DM, p<0.001. Improvement in PS was independently associated with decreases in HbA1c, CGM BG and SD (all p<0.015). PH improved with decreased CGM BG, SD and % time > 7.8 mmol/l (all p<0.05).

Table 1. Glycemic Control and Variability During Period 1 Treatment

Period 1	GG Baseline	GG Wk 12	PM Baseline	PM Wk 12
HbA1c (%)	7.8±0.05	7.1±0.05*	7.8±0.05	7.4±0.06
BG (mmol/l)	9.7±0.10	8.2±0.09*	9.7±0.09	9.1±0.09
SD (mmol/l)	2.7±0.04	2.4±0.05*	2.7±0.04	2.7±0.04
% time > 7.8 mmol/l	63.0±1.0	46.5 ±1.1*	63.9±1.0	55.6±1.0
% time < 3.9 mmol/l	5.3±0.4	7.4±0.4 (ns)	5.4±0.4	5.8±0.4

Conclusion: Lower CGM variability was associated with insulin glargine plus glulisine vs premix, and was predictive of improved PS and PH. Glucose variability was higher with increased HbA1c and lower among T2DM, older, and higher weight patients. CGM variability, PS, and PH are useful patient-oriented measures to evaluate the comparative effectiveness of diabetes treatments.

Continuous glucose monitoring: effect on glucose control and treatment satisfaction in diabetes mellitus type 1

L.L. Langeland[1], Ø. Salvesen[1], H. Selle[2], S.M. Carlsen[1,2], K.J. Fougner[1,2];
[1]Norwegian University of Science and Technology, [2]St. Olavs Hospital, Trondheim, Norway.

Background: The effect of a continuous glucose monitoring system (CGMS) on glucose control in patients with diabetes type 1 has been explored in several studies. These have reached different conclusions, and the value of a CGMS used for short periods of time has yet to be determined.
Material and methods: In a randomized controlled cross-over trial we assessed whether one month's use of a CGMS (Medtronic Guardian RT) lowers HbA_{1c} levels and frequency of hypoglycemic episodes, compared to intensified conventional finger-prick measurements (ICFM) in patients with diabetes type 1. Treatment satisfaction (DTSQ) and health status (SF-36) was also assessed. Thirty patients (mean age 34 ± 9 yrs) with moderately good glucose control (HbA_{1c} 7.0 - 10.0%) were included in the study. They were randomized to perform either ICFM or CGMS of blood glucose for one month followed by a two months wash-out (observation) period before they were crossed over to the opposite intervention. HbA_{1c} was measured both at the end of the intervention period and the wash-out period.
Results: At inclusion mean HbA_{1c} was 7.84 ± 0.94%. The mean change in HbA_{1c} was -0.23 ± 0.10% for the CGMS period and -0.24 ± 0.09% for the ICFM period (p = 0.91). The mean change in HbA_{1c} during treatment and washout periods was -0.14 ± 0.09% for the CGMS period and -0.16 ± 0.08% for the ICFM period (p = 0.86). The frequency of hypoglycemic events was 8.2 ± 1.6 during CGMS period and 7.3 ± 1.4 during the ICFM period (p = 0.67). Treatment satisfaction and health status were also equal between treatments.
Discussion: This study does not support previous findings that CGMS is superior to ICFM in order to lower HbA_{1c} or reduce the burden of hypoglycemic episodes in adults. It could be argued that our results are based on a limited number of patients, evaluated over a short period of time, and in a patient population with moderate problems with glucose control and hypoglycemic episodes. However, we used a crossover design making the patients their own controls which strengthens the validity of our findings. The mean HbA_{1c} level was fairly low at inclusion. This may have contributed to the small decline in HbA_{1c} levels during intervention and the absence of a superior effect of GCMS in achieving good blood glucose control with less hypoglycemic events. CGMS compared to ICFM did not improve treatment satisfaction. Remarks from the participants indicate that the burden of carrying an electronic device outweighted the benefit of real-time information on glucose levels.
Conclusion: In conclusion the present study shows that the average blood glucose, evaluated by HbA_{1c}, decreased equally in both patients performing frequent self-monitoring of blood glucose, and in patients carrying a continuous glucose monitoring system for one month. The frequency of hypoglycemic episodes and treatment satisfaction were also equal in the two intervention periods. Future studies should aim at identifying subgroups of patients that show a clear benefit of using a continuous glucose monitoring system for a short time period.

Insulin initiation in accordance to NICE guidance: audit and review of Trust practice

S. Dampetla, J.M. Ng, A.J. Dawson, D.D. Mellor, J. Patmore, C. Walton;
Diabetes and endocrinology, Hull Royal Infirmary, United Kingdom.

Background and aims: National Institute of Clinical Excellence (NICE) in the UK most recent guidance on the management of patients with type 2 diabetes mellitus (T2DM) were published in 2008 A key recommendation of this guidance was to recommend the use of NPH insulin over basal analogue insulins. These changes were performed in the light of evidence by the committee showing no definitive advantage on the use of basal analogue insulin therapy in all patients with T2DM. From mid 2008, the diabetes specialist team in our Trust changed its insulin prescribing trends in parallel with NICE guidelines. This was following the service undergoing a review using programme budgeting marginal analysis (PBMA), a methodology that uses cost savings made from one aspect of the service and reinvest in another aspect.
Materials and methods: All patients with T2DM initiated on insulin therapy by the specialist team from February 2009 to January 2010 inclusive were included in the analysis. Data of prescribing trends and patient information was obtained from electronic diabetes record system, clinical handwritten notes and dictated letters. The decision for insulin initiation was undertaken by the specialist diabetes team for all patients. Patients were started on insulin both in community and hospital care settings. Initiation of basal therapy was in concordance with NICE insulin prescribing recommendations. Cost for insulin and savings were based on an average patient use of 40 units of insulin a day and the current market price for insulin.
Results: There were a total of 82 patients (39M, 43F, median age 65 years (IQR 55-77)) patients with T2DM who were commenced on basal insulin therapy over the study period.. There were a total of 75.6% (n=62) patients initiated on NPH therapy and 24.4% (n=20) patients commenced on insulin analogues. This was a change from the prescribing pattern of 79.1% analogue insulin and 20.9% insulin NPH during the previous year. Mean HbA1c of insulin on patients on NPH improved from (mean±SE) 10.4±0.2% to 9.1±0.3% and for analogue insulin 10.9±0.6% to 9.8±0.7%. There was no difference between Hba1c levels pre and post insulin therapy between the two groups. (Mann Whitney U test). For the NPH group, there were 20 (32.2%) patients who self reported hypoglycaemia compared to 4 (20%) patient on analogue (p=0.23, chi squared test). There were no episodes of severe hypoglycaemia where third party intervention was required over the study period. The total cost savings calculated over the period based on the change in insulin prescribing from the previous year was over £ 14,300.
Conclusion: From 2002 to 2008 in England, the number of diabetes items prescribed increased by 73.3% and the total cost has risen by 93.2%. Similarly, prescribing costs for intermediate insulin and long acting insulin has increased by 13.4% from the year 2007 to 2008. There is currently no conclusive evidence in the literature to support the use of basal analogue insulin in improving mortality, morbidity or quality of life in all treated patients over the NPH insulin. The selection of patients continuing to be initiated on insulin analogues introduced a bias into the review, in that they were more likely to be residing in institutional care, therefore our data does not suggest a difference in hypoglycaemia rates. The findings of our study illustrate the cost savings that can be achieved which could be reinvested in diabetes services, it is likely over time the cost savings are likely to increase by at least this amount on a yearly basis.

1060

Structured blood glucose monitoring reduces HbA_{1c} levels and annual test strip consumption in poorly controlled, non-insulin treated type 2 diabetes: results from the STeP Study

O. Mast[1], W. Polonsky[2], L. Fisher[3], C. Parkin[4], Z. Jelsovsky[5], M. Schweitzer[1], R. Wagner[1];
[1]Roche Diagnostics Corporation, Indianapolis, [2]University of California, San Diego, [3]University of California, San Francisco, [4]Health Management Resources, Inc., Carmel, [5]BioStat International, Tampa, USA.

Background and aims: Conclusions from recent systematic reviews have been inconsistent regarding the cost-effectiveness of self monitoring of blood

glucose (SMBG) in insulin-naïve type 2 diabetes (T2DM). The Structured Testing Protocol (STeP) study examined the utility of structured SMBG in comparison to enhanced usual care (which included SMBG based on USA standard of care recommendations) in this population. We hypothesized that structured SMBG would be associated with improved HbA1c outcomes without increasing test strip consumption, compared with standard SMBG use.
Materials and methods: The STeP study is a prospective, cluster-randomized, multi-center, clinical trial with 522 poorly-controlled (HbA1c ≥7.5%), insulin-naïve T2DM subjects who were assigned to a structured testing protocol (STG) or an active control (ACG). STG subjects used the Accu-Chek® 360° View Blood Glucose Analysis System, an easy-to-use paper tool that facilitates collection and interpretation of 7-point glucose profiles over 3 consecutive days. STG subjects completed the tool on a quarterly basis and brought it to medical visits. All STG subjects received standardized instruction in SMBG, pattern recognition and interpretation. STG physicians received an algorithm for suggested medication strategies in response to observed SMBG patterns. All STG and ACG subjects received free blood glucose meters and test strips. Test strip consumption was measured using electronic data uploaded from blood glucose meters in both study groups.
Results: Although both groups demonstrated significant reductions in HbA1c over 12 months, intent-to-treat analysis showed a significantly greater HbA1c reduction in the STG than in the ACG (-1.2% vs. -0.9%; Δ=-0.3%; p=0.04). SMBG frequency was negatively associated with HbA1c in both groups ($p<0.05$) over time. However, STG subjects performed significantly fewer tests/day than ACG subjects (mean = 0.9 vs. 1.2, p=0.0003) over the 12 months. Extrapolating over time, this equates to a 25% difference in annual test strip consumption between the STG (329 tests/year) and ACG (438 tests/year).
Conclusion: Structured SMBG use was associated with greater reductions in HbA1c compared with standard SMBG use, and structured SMBG use required 25% less test strip consumption on average over the 12-month period than the standard approach. Therefore, structured SMBG use may be a more cost-effective approach to improving glycemic control in poorly controlled, non-insulin treated T2DM.

1061

Healthcare costs of fast-acting insulin analogues vs. short-acting human insulin in combination with long-acting insulin analogues for Danish patients with type 2 diabetes

J. Gundgaard[1], T. Christensen[2], T. Thomsen[2];
[1]Health & Economics, COWI A/S, Kongens Lyngby, [2]Novo Nordisk A/S, Virum, Denmark.

Background and aims: The aim of this study was to compare the direct healthcare costs incurred by patients with type 2 diabetes (T2D) on a basal-bolus regimen using either fast-acting insulin analogues (Insulin Aspart, Insulin Lispro or Insulin Glulusine) or short-acting human insulin. Due to local registry regulations it was not possible to analyse brand specific data.
Materials and methods: Data were extracted from registers covering the total Danish population, and included prescription data, in- and outpatient hospital data, primary care data, and demographic variables. Patients were identified in a 1-year inclusion period (2005). Inclusion criteria were at least 2 prescriptions in the index period of a long-acting insulin analogues in combination with either fast-acting insulin analogues or short-acting human insulin with no switch to the other product during follow-up. Patients with at least one oral antidiabetic drug prescription were included as T2D, and patients with >1 prescription of fast-acting insulin analogues or short-acting human insulin were classified as basal-bolus. Individual patients from the fast-acting insulin analogues group (n=445) were matched individually with patients from the short-acting human insulin group (n=85) with respect to observable variables using propensity scores. Annual healthcare costs were extracted and analysed for a follow-up period of maximum 2 years after the inclusion date.
Results: Overall annual direct healthcare costs, including prescription medicine, amounted to €4,163 in the fast-acting insulin analogue group and €5,130 in the short-acting human insulin group. Bolus insulin treatment costs were significantly higher for patients using fast-acting insulin analogues compared to patients using short-acting human insulin (€521 vs. €445). However, these costs were offset elsewhere in the health care system. Hospital cost estimates were considerably lower for the analogue group (€1,738 vs. €2,647). Given the small sample size, bootstrapped confidence intervals showed that the cost reductions were not statistically significant.
Conclusion: Using a matched cohort technique, patients with T2D on a basal-bolus regimen and fast-acting analogues are not more costly to the Danish healthcare system than patients using short-acting human insulin despite higher insulin costs. The register-based study is ongoing and is expected to be updated with a longer time-horizon and more complete hospital data.

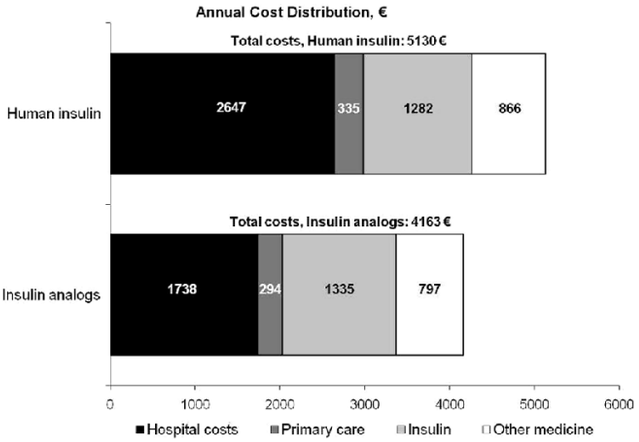

Figure. Follow-up annual healthcare costs 2005/6. Exchange rate: Average of 2006.

Comparison of adherence and cost outcomes in patients with type 2 diabetes initiating rapid-acting insulin analogue with a prefilled pen versus vial/syringe

L.J. Lee[1], Q. Li[2], M.W. Reynolds[2], K. Sarsour[1], S.M. Corrigan[3];
[1]Global Health Outcomes, Eli Lilly and Company, Indianapolis, [2]United BioSource Corporation, Lexington, [3]US Medical Division, Lilly USA, LLC, Indianapolis USA.

Background and aims: Outcomes data on insulin pens compared to vial/syringe for rapid-acting insulin analog (RAIA) are limited in the literature. The aim of this research was to compare the adherence and cost outcomes of a newly available prefilled pen with insulin lispro vs. vial/syringe with insulin lispro or aspart in patients with type 2 diabetes (T2D). RAIA in premixed formulations were not included due to small sample size.
Materials and methods: A retrospective analysis was conducted using a US claims database. The study included patients who were ≥18 years old, new initiators of RAIA, with T2D, and ≥12-month continuous eligibility of medical and pharmacy benefits. After using a propensity score matching technique to match the 2 study cohorts, a difference-in-difference analysis was conducted by comparing the mean change in outcomes from 6 months prior (pre-index) to 6 months after (post-index) initiating the prefilled pen vs. vial/syringe. The Wilcoxon rank sum test was used to test for significance of the differences in outcomes across the 2 cohorts. Adherence was measured by dividing the number of days with RAIA by the 6-month post-index period (range: 0-100% with a higher percent indicating higher adherence). Cost outcomes (2009 US Dollars) included total costs, diabetes-related costs, and the subgroups of pharmacy, outpatient, emergency room (ER), and inpatient costs.
Results: Post-matched baseline patient characteristics including cost measures were similar between the prefilled pen (n=239) and vial/syringe (n=590) cohorts. Mean age and percentage of females were 59 vs. 60 years (p=0.22) and 47% vs. 48% (p=0.67), respectively. Adherence to the newly initiated RAIA in the post-index period was higher in the prefilled pen cohort than the vial/syringe cohort (55% vs. 45%; $p<0.001$). The increase in diabetes-related pharmacy costs after RAIA initiation was significantly greater in the prefilled pen cohort than the vial/syringe cohort (Table 1). A significant reduction in total diabetes-related costs was observed in the prefilled pen cohort when compared to the vial/syringe cohort (Table 1). There were no significant differences in changes to total costs, diabetes-related outpatient, ER, or inpatient costs between the 2 cohorts.
Conclusion: Our findings suggest that even with a greater increase in diabetes-related pharmacy costs, initiating RAIA with a prefilled pen was associated with greater adherence and lower total diabetes-related costs than vial/syringe. Further research is needed to elucidate the key drivers of this greater reduction in the total diabetes-related costs.

Table 1: Results of Diabetes-Related Pharmacy and Total Costs

Diabetes-related costs (mean, US Dollars)	Prefilled Pen			Vial/Syringe			
	Pre-Index	Post-Index	Difference from pre- to post-index	Pre-Index	Post-Index	Difference from pre- to post-index	p-value of difference-in-difference
Pharmacy costs	963	1,864	+901	880	1,486	+606	<0.001
Total costs	3,049	2,814	-235	2,914	2,975	+61	0.01

1063

German real-life data indicate lower costs for basal supported oral therapy (BOT) with insulin glargine compared to combination therapy with exenatide and oral antidiabetic drugs

S.M. Fuchs[1], F.-W. Dippel[2], K. Kostev[3], W. Kotowa[1];
[1]Health Economics & Outcomes Research, IMS Health GmbH & Co. OHG, Nuernberg, [2]Evidenzbasierte Medizin und Gesundheitsökonomie, Sanofi-Aventis Deutschland GmbH, Berlin, [3]IMS Health GmbH & Co. OHG, Frankfurt/Main, Germany.

Background and aims: Clinical efficacy of the new antihyperglycaemic injectable exenatide (EXE) in combination with oral antidiabetic drugs (OAD) is reported to be comparable to basal supported oral therapy (BOT) with insulin glargine (GLA). This study investigated the costs of a combination therapy of exenatide (EXE) and OAD vs. a BOT with GLA in type-2-diabetics (T2D) in Germany based on real-life data.
Materials and methods: A historical cohort study was performed using a representative patient database (IMS® Disease Analyzer). T2D who initiated a BOT with GLA or a combination therapy with EXE and OAD between 1/2007 and 12/2008 and whose data were continuously documented at least 12 months before and 12 months after therapy initiation were included. The following variables were collected: age, gender, insurance status, region and specification of the practice, diabetes duration, HbA1c level and BMI. Resource utilization (RU) and costs (based on public prices) were determined for a time period of 12 months after initiation of therapy with GLA (BOT) and EXE (OAD), respectively. The diabetes-related direct treatment costs (DR-costs) were identified for both treatment regimens, containing GLA, EXE, OADs, glucose [i.v.]/glucagon, blood glucose test strips (BGT strips) and consumables such as lancets and needles. Additionally, direct costs for co-medication (antihypertensive, lipid lowering, antithrombotic and cardiovascular drugs) were assessed for GLA (BOT) and EXE (OAD). RU included the evaluation of the number of physician visits, referrals to specialists and hospital admissions. Applying regression analysis, adjusted RU and costs for GLA (BOT) vs. EXE (OAD) were calculated. The variables age, gender, specification of the practice, region, diabetes duration, HbA1c level and BMI were included into the model.
Results: 1,934 T2D were included, of which 1,484 received GLA (BOT) and 450 patients were treated with EXE (OAD). GLA-patients were older (70.2 years vs. 58.1 years; p<0.0001), had a longer diabetes duration (5.4 years vs. 3.9 years; p<0.0001), a higher HbA1c level (7.6% vs. 7.3%; p<0.0001) and a lower BMI (30.7kg/m^2 vs. 35.6 kg/m^2; p<0.0001) than EXE-patients at baseline. The unadjusted annual DR-costs were 1,068 € for GLA (BOT) and 1,740 € for EXE (OAD) (Δ = 672 €). The total adjusted annual DR-costs were lower in T2D on GLA (BOT) than on EXE (OAD); cost savings amounted to 640 € (p<0.0001) per year. This is mainly driven by the lower costs of GLA compared to EXE (Δ = 809 €; p<0.0001). Additionally, a cost advantage of GLA (BOT) vs. EXE (OAD) was found for the use of consumables (Δ = 37 € p<0.0001). In contrast, the adjusted cost of BGT strips were lower in EXE-patients than in GLA-patients (Δ = 203 €; p<0.0001). No significant differences were found for the expenses of OAD and co-medication, as well as for RU in both groups.
Conclusion: A randomized controlled trial showed similar efficacy of EXE and GLA, both in combination with OADs. This cost comparison yielded substantial cost savings in favour of the GLA treatment regimen. After adjustment the cost advantage of GLA remained stable. Therefore, the BOT treatment based on GLA compared to a combination therapy of EXE and OAD in T2D could lead to relevant cost savings in Germany.

Resource utilization and diabetes-related treatment costs of type-1-diabetics treated with ICT based on insulin glargine, insulin detemir or NPH insulin in Germany

R.A. Bierwirth[1], F.-W. Dippel[2], K. Kostev[3], S.S. Fuchs[4], W. Kotowa[4];
[1]Ambulantes Diabteszentrum am Elisabeth-Krankenhaus, Essen, [2]Sanofi-Aventis Deutschland GmbH, Berlin, [3]IMS Health GmbH & Co. OHG, Frankfurt/Main, [4]Health Economics & Outcomes Research, IMS Health GmbH & Co. OHG, Nuernberg, Germany.

Background and aims: The chronic course of the disease and the specific long-term complications of type 1 diabetes mellitus lead to substantial costs for the German health care system. Hence, the cost-effectiveness of different insulin formulations is gaining increasing importance. The aim of this study was to compare resource utilization and associated direct treatment costs of an intensified conventional therapy (ICT) with three different basal insulins in type-1-diabetics: human basal insulin (NPH), insulin glargine (GLA) and insulindetemir (DET).
Materials and methods: Type-1-diabetics who had started an ICT with NPH, GLA or DET between 7/2000 and 2/2008 were identifyed by using a representative German database (IMS® Disease Analyzer). Patients whose data were continuously documented at least 12 months before and 18 months after initiation of an ICT were included. Patients who had a prescription of premixed insulin or were switched to another basal insulin within the observational period were excluded. The following variables were collected: age, gender, diabetes duration, HbA1c-level, Body Mass Index (BMI), insurance status (private versus statutory), geographical region and specification of the practice. Resource utilization was determined for a time period of 12 months and included the evaluation of basal and bolus insulin, blood glucose test strips, number of physician visits (general practitioner and specialist) and hospital admissions. Diabetes-related direct treatment costs (insulin, test strips, lancets, pens, needles, glucose i.v., glucagon) were calculated based on public prices for patients receiving NPH, GLA and DET, respectively. Finally, the evaluated resources and costs were adjusted for the variables age, gender, diabetes duration, HbA1c-level, BMI, specification of the practice and region, applying a multivariate regression model.
Results: 2,740 type-1-diabetics were included, of which 1,218 received an ICT with NPH, 1,079 with GLA and 443 with DET, respectively. The unadjusted annual diabetes-related direct treatment costs were 1,308 € for NPH, 1,512 € for GLA and 1,729 € for DET. After adjusting for potential confounders ICT with GLA showed economic advantages compared to ICT with NPH (-234 €/year; p<0.0001) or DET (-425 €/year; p=0.2800). The consumption of basal insulin and test strips was lower in patients treated with GLA compared to NPH (-6.00 U/day; p=0.3514 und -0.31 units/day; p=0.8291) or DET (-3.23 U/day; p<0.0001 und -0.59 units/day; p=0.0235). The number of referrals to specialists was lower for patients with GLA than in DET treated patients (-0.51/year; p=0.0009) but higher than in NPH treated patients (0.16/year; p=0.9184).
Conclusion: After adjustment for potential confounders this analysis of German real-life data showed that the ICT with GLA is related to lower annual treatment costs than the ICT with NPH or DET. In view of the equal clinical efficacy as reported in several randomized clinical trials and the economic advantages in comparison to NPH or DET, GLA should be regarded as the favored therapeutic option for type-1-diabetics in Germany.

Acute day hospital for medical care of hyperglycaemic crises in the last years of life

J.F. Cano[1], C. Claret[1], D. Benaiges[1], J. Puig[1], M. Carrera[1], F. Cots[2], E. Corominas[1], J. Flores[1], J. Chillaron[1], A. Goday[1];
[1]Endocrinology and Nutrition, [2]Sevei d'Estudis, Hospital Universitari del Mar, Barcelona, Spain.

Background and aims: Hyperglycemic crises in oldest elder people have usually been treated in a hospitalization ward. The inhospital management is an expensive way of care and it may involve nosocomial complications. There are no studies comparing effectiveness and feasibility of Day Hospital treatment versus conventional hospitalization for patients older than 74 years. Aims: 1.To assess the effectiveness of treating acute complications of diabetes (ACD) in a day hospital (DH) versus conventional hospitalization (CH) in older elder patients. 2. To evaluate glycaemic control at 3-6 months in both

groups. 3. To compare short term re-admissions (3 months) due to diabetes and nosocomial morbidity between study groups.
Materials and methods: A prospective, non randomized, cohorts study with 6 months follow-up. We included all diabetic patients aged >74 years consecutively admitted in our hospital, with ketosis and/or acute hyperglycemia >300 mg/dl. We excluded patients presenting with HC03 < 14 mEq, pH < 7.20, blood glucose >600 mg/dl, hemodynamic instability, severe intercurrent illness (infectious, CV disease ....), or Activities of Daily Living > D (Katz Index). Patients were assigned to DH or CH according to time of admission to the emergency-room. If patients were admitted out of DH opening hours they were assigned to CH. AII patients included in the CH cohort could have been treated in DH if they had arrived during the DH-opening hours. Investigators did not participate in group assignment The cost calculation included structural cost and all visits (emergency ward, day hospital and outpatients consultations).
Results: During the four years study period, 101 patients met the inclusion criteria. 64 were attended in DH and 37 in CH. The average age was 80.5 ± 4.7 years (range 75-95), and there were 62.7% females, without differences between the groups. Cause of admission was acute hyperglycemia in 63.4% and Ketosis in 36.6%. Infection (37.5%) was the most common cause of ACD, followed by new onset diabetes (11.5%) and corticosteroid therapy (12.5%). During the first 15 days after dischange we observed 4 severe hypoglycemic events without differences between groups. The average cost per patient and year was 584,9 euros for the DH cohort and 1.796,0 euros for the CH group.
Conclusion: Our results prove the effectiveness and safety of ACD management in Day Hospital with a net economic saving of 1.211,1 euros/case with no differences in short term glycaemic control and hypoglycemic events, and with less frequent readmissions and pressure ulcers.

	DAY HOSPITAL	Hospitalization	significance
Charlson index	3.22 ± 2.0	3.22 ± 1.7	p>0.05
Katz index (A or B%)	73	72.2	p>0.05
Blood Glucose (mg/dl)	420 ±74.8	449 ± 97.8	p>0.05

Cost-effectiveness analysis of medical intervention in patients with early detection of diabetic retinopathy in a tertiary care hospital in Bangladesh
S.H. Habib, S. Saha, L. Ali;
Health Economics Unit, BADAS, Dhaka, Bangladesh.

Background and aims: The economic burden resulting from diabetic retinopathy (DR) consumes a major portion of resources allocated for health-care services. Cost-effectiveness of various interventions on DR and its complications has relatively been well explored in developed countries, but these are almost absent in developing countries. The present study was undertaken to assess the cost-effectiveness of medical intervention in patients with DR.
Materials and methods: Two hundred patients with DR, with at least 1 year of follow-up, were purposively selected from the Out-Patient Department of BIRDEM (tertiary diabetes care hospital), Bangladesh. Of them 100 were late in detection of DR (LDR) & 100 were detected early (EDR). The degree & extent of complications like cardiopathy, peripheral neuropathy, nephropathy & vasculopathy, treatment outcome, clinical effectiveness of interventions and direct, indirect & incremental cost of complications were calculated. Comparison was made between the groups. Cost included drugs, hospitalizations, diagnostics & visits.
Results: A total of 200 patients were considered for an average of 365 days, amounting to 656 person-years of observation in total. In LDR group, 42.4% had mild nonproliferative DR (NPDR), 31.4% had moderate, 15.1% had severe NPDR & 11.1% had proliferative DR (PDR). In EDR group, 58.4% had mild and 41.6% had moderate NPDR. The mean±SD fasting serum glucose of the groups (LDR & EDR respectively) was 9.36±0.40 & 4.78±0.38 mmol/l, total cholesterol was 206.50±42.60 & 104.20±35.50 mg/dl, HbA_{1c} was 9.80±0.50% & 5.70±0.38%, TG was 163.76±99.46 & 155.67±94.84 mg/dl, SBP was 172.5 ± 20.9 & 109.5±11.9 mmHg and DBP was 97.7±10.0 & 70.7±9.3 mmHg. About 17% patients in LDR & 34% in EDR were free of diabetic complications other than DR. In LDR & EDR, 18% & 46% had one complication, 27% & 8% had two and 30% & 4% had more than two complications respectively. The most frequent complication was cardiopathy, which affected 31% patients in LDR & 25% in EDR, followed by peripheral neuropathy 19% & 16%, nephropathy 15% & 11%, and vasculopathy 8 % & 4% respectively. The average annual cost of care was US$ 27954 (direct US$ 16983 & indirect US$ 10971), with an average US$ 140 per patient. Among the average annual cost LDR consumed US$ 19737 (US$ 197 per patient) & EDR US$ 8217 (US$ 82 per patient). US$ 13473 (48%) of costs was attributable to drugs for both groups of which US$ 10817 (80%) was for LDR & US$ 2656 (20%) for EDR, US$ 8739 (31%) to hospitalizations of which US$ 5211 (60%) for LDR & 3528 (40%) for EDR. In case of diagnostics & visits the corresponding values were US$ 2136 (60%) & 1419 (40%) and US$ 1673 (76%) & 514 (24%) for LDR & EDR respectively. The annual medical costs increased with the increased number of complications from US$ 1322 to 2298 & to 3991 in LDR with one, two & more than two complications (other than DR) which is increasing at a rapid rate and US$ 917 to 1556 & to 2372 in EDR respectively, increasing at a diminishing marginal rate. The regression equation showed that medical cost is significantly related to complications tested in both univariate ($P<0.0001$) & multiple linear regression analyses ($R^2=0.53$; $F=82.3$, $P<0.0001$).
Conclusion: Proper management with regular screening substantially reduces the expenditure related to care of patients with diabetic retinopathy & related complications even in a developing country. Strategies aimed at preventing DR & early detection of the onset of retinopathy will reduce medical costs in a substantial way.

Assessment of medication adherence among patients with type 2 diabetes
M. Linnemann Jensen, B. Carstensen, A. Nielsen, T.P. Almdal, D.R. Witte, P. Rossing;
Steno Diabetes Center A/S, Gentofte, Denmark.

Background and aims: Poor adherence to prescribed medication may markedly limit physicians' ability to achieve and maintain adequate glycaemic and cardiovascular risk control in patients with diabetes. However, much remains unknown about patterns of adherence to treatment in patients with complex treatment strategies. We sought to assess and summarize patterns of medication adherence to oral anti-diabetic medication in patients with type 2 diabetes (T2DM), attending a specialised diabetes hospital in Copenhagen.
Materials and methods: Registrations of drug prescriptions issued by physicians at the outpatient clinic for type 2 diabetic patients followed for at least two years between 2002 and 2007 were linked to registrations of filled prescriptions at Danish pharmacies at an individual level. Medication episodes were defined based on prescriptions issued at the hospital. Within each episode the number of days with and without adherence was calculated based on pharmacy data. A binomial regression model was used to assess the association between the degree of adherence and sex, age and duration of diabetes.
Results: 1,634 patients with T2DM (60.5% men, mean age at entry: 59.4 years (men), 60.3 years (women), mean duration of diabetes at entry: 9.7 years (men), 10.5 years (women), with an average clinic attendance duration of 4.3 years contributed with over 7,000 person-years of time. The median degree of adherence was 0.85. An adherence ratio of 0.73 and above was achieved by 75% of the patients. More than 15% of the patients were adherent to treatment less than half the time. We found a higher degree of adherence by increasing age. Women at age 60 with a duration of diabetes of 10 years had a 2.6 %-points higher degree of adherence than women at age 50. There was no statistically significant difference between men and women or according to duration of diabetes.
Conclusion: The degree of adherence to oral anti-diabetic medication ranged from not picking up any prescription to full adherence. Only age was positively associated with the degree of adherence. Further explanatory factors such as socio-economic variables and analysis of adherence patterns to statins, antithrombotic and anti-hypertensive medication deserve consideration. Our findings indicate that a considerable improvement in glycaemic control can be achieved by improving adherence to medication.

Foetal exposure to maternal diabetes is associated with insulin secretory defect in females at adult age

L.-S. Fetita[1,2], P. Boudou[1], S. Choukem[4], J.-P. Riveline[5], S. Hadjadj[6], C. Abi Khalill[7], E. Larger[8], L. Morbois[9], T. Meas[10], A. Penfornis[11], R. Porcher[1], P. Vexiau[1], M. Marre[7], F. Calvo[1], J.-F. Gautier[1,2];
[1]Saint-Louis Hospital, Paris, France, [2]Centre de Recherche des Cordeliers, INSERM, U 872, Paris, France, [4]Medecine and Diabetes, Douala General Hospital, Douala, Cameroon, [5]Diabetes and Endocrinology, Centre Hospitalier Sud Francilien, Corbeil-Essonne, France, [6]Diabetes and Endocrinology, CHU Poitiers, France, [7]Diabetes and Endocrinology, Bichat Hospital, Paris, France, [8]Diabetes and Endocrinology, Hotel Dieu Hospital, Paris, France, [9]Diabetes and Endocrinology, Institut Mutualiste Montsouris, Paris, France, [10]Diabetes and Endocrinology, Lariboisiere Hospital, Paris, France, [11]Diabetes and Endocrinology, CHU Besançon, Paris, France.

Background and aims: In humans, excess maternal transmission of type 2 diabetes supports the hypothesis that the intrauterine environment contributes to increased risk of type 2 diabetes in offspring. We have shown that fetal exposure to maternal diabetes is associated with an insulin secretion defect in response to glucose at adult age. The aim of the present study was to investigate whether fetal exposure to maternal diabetes is associated with a global (endocrine and exocrine) pancreatic dysfunction in non diabetic adult offspring.
Materials and methods: We investigated offspring of type 1 diabetic patient to circumvent the confounding effect of genetic factors related to type 2 diabetes. 29 adult offspring exposed to maternal type 1 diabetes during pregnancy (exposed group) were compared with 29 offspring of type 1 diabetic fathers (control group). Early insulin secretion in response to oral glucose defined as the ratio of Δ insulin $_{0\text{-}30}$ to Δ glucose $_{0\text{-}30}$ was measured during OGTT. Insulin and glucagon secretion were assessed during graded glucose infusion from 4 to 16 mg/kg/min followed by a 5-g arginine bolus. Insulin action was measured using a euglycemic hyperinsulinaemic clamp and percent body fat mass by DEXA. Exocrine pancreatic function was evaluated by quantitative stools analyses.
Results: Mean age, sex ratio, mean percent body fat and mean insulin sensitivity were similar in the exposed and control groups: 25.9 ± 6.2 (SD) vs 26.2 ± 6.1 years, 55 (F/M) vs 52 %, 26.3 ± 8.7 vs 24.5 ± 7.9% fat mass and 11.5 ± 2.9 vs 11.7 ± 2.5 mg/kg of body fat free mass/min respectively. Impaired glucose tolerance was diagnosed in two offspring in each group. Early insulin secretion was lower in the exposed group than in the control group: 7.8 (median) (5.5-10.6 Q1-Q3) vs 11.3 (6.4-17.1) µUI/mmol (p = 0.06). In response to IV glucose and arginine there was no difference between the 2 groups with respect to insulin secretion and glucagon concentrations. However, women exposed in utero to maternal diabetes had a significantly decrease in insulin secretion rate compared to those of the control group: 12.5 ± 4.5 vs 15.2 ± 5.2 pmol/kg/min (p=0.03). Fecal fat output was similar in the 2 groups but fecal chymotrypsin activity was significantly lower in the exposed group: 14.5 ± 7.2 vs 22.8 ± 13 U/g (p = 0.016).
Conclusion: Fetal exposure to maternal type 1 diabetes seems to be associated with a global pancreatic dysfunction at adult age. Insulin secretory defect in response to IV glucose is only observed in women suggesting sex-dependent epigenetic mechanisms.

Glycaemic control, pre-eclampsia and gestational hypertension in pregnant women with type 1 diabetes

V.A. Holmes[1], I.S. Young[2], C.C. Patterson[2], D.W.M. Pearson[3], J.D. Walker[4], M.J.A. Maresh[5], D.R. McCance[6], Diabetes and Preeclampsia (DAPIT) Study Group;
[1]School of Nursing and Midwifery, Queen's University Belfast, [2]Centre for Public Health, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, [3]Department of Diabetes, Aberdeen Royal Infirmary, [4]Department of Diabetes, St. John's Hospital at Howden, West Lothian, , [5]Department of Obstetrics and Gynaecology, St Mary's Hospital for Women and Children, Manchester, [6]Regional Centre for Endocrinology and Diabetes, Royal Victoria Hospital, Belfast, United Kingdom.

Background and aims: An association between glycaemic control and preeclampsia has been reported but the results are conflicting and the rela-

tive importance of early and late control for hypertensive complications of pregnancy remains unclear. The aim of this study was to assess the relationship between glycaemic control, preeclampsia and gestational hypertension in women with type 1 diabetes.
Materials and methods: HbA1c measurements were available from women taking part in the Diabetes and Preeclampsia Intervention Trial (a multicentre randomized controlled trial investigating the effect of antioxidants on the incidence of preeclampsia) at up to 6 months pre-pregnancy, at the first antenatal visit (booking), and at 26 and 34 weeks gestation. Results were categorized as poor (>8%), moderate (7-8%) and good (<7%) glycaemic control. Preeclampsia and gestational hypertension were defined using the International Society for the Study of Hypertension in Pregnancy guidelines. Logistic regression was used to estimate the odds on preeclampsia and gestational hypertension in women with poor and moderate control relative to women with good control both before and after adjustment for potentially confounding variables.
Results: Preeclampsia and gestational hypertension developed in 17% and 11% of pregnancies, respectively. Poor/moderate glycaemic control both before and during pregnancy were associated with significantly increased risk of preeclampsia compared with good glycaemic control. After adjustment for confounding variables the association between HbA1c and preeclampsia remained significant throughout pregnancy with highest odds ratios observed in the last trimester (see table). Glycaemic control during pregnancy was not significantly associated with gestational hypertension either before or after adjustment for confounders.

Glycaemic control before and during pregnancy and risk of preeclampsia and gestational hypertension

Time-point	n	Glycaemic control (HbA1c)	Preeclampsia*	Gestational hypertension*
Pre-pregnancy	542	<7%	1.00	1.00
		7-8% vs <7%	1.70 [0.79-3.64]	0.62 [0.30-1.29]
		>8% vs <7%	2.53 [1.19-5.36]	0.72 [0.36-1.43]
First antenatal visit	721	<7%	1.00	1.00
		7-8% vs <7%	2.29 [1.22-4.31]	1.00 [0.54-1.86]
		>8% vs <7%	3.46 [1.83-6.55]	0.91 [0.49-1.72]
26 weeks gestation	592	<7%	1.00	1.00
		7-8% vs <7%	2.01 [1.17-3.47]	0.80 [0.41-1.54]
		>8% vs <7%	2.15 [0.84-5.50]	0.79 [0.26-2.46]
34 weeks gestation	519	<7%	1.00	1.00
		7-8% vs <7%	2.32 [1.14-4.72]	1.09 [0.53-2.24]
		>8% vs <7%	5.87 [1.64-21.1]	0.79 [0.16-3.80]

*Adjusted Odds Ratio [95% Confidence Interval]. Adjusted for: treatment group, centre group, BMI, diabetes duration, parity, smoking, age, plasma ascorbate and serum α-tocopherol at randomisation, microalbuminuria before pregnancy.

Conclusion: Poor glycaemic control is associated with an increased risk of preeclampsia but not gestational hypertension. While glycaemic control is important before and throughout pregnancy, HbA1c during the last trimester of pregnancy is the strongest predictor of preeclampsia.

In women with type 1 diabetes mellitus, maternal insulin requirements are potent predictors of excess fetal growth
D. Ovejero[1], I. Miñambres[1], A. Chico[1], A. García-Patterson[1], J.M. Adelantado[2], A. de Leiva[1], R. Corcoy[1];
[1]Endocrinology and Nutrition, [2]Gynaecology and Obstetrics, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Background and aims: Excessive fetal growth remains as an important issue in diabetic pregnancies, glycemic control being one among other predictor variables.
Materials and methods: To perform a comprehensive analysis of potential predictors of excessive fetal growth Singleton pregnancies of women with T1DM delivering in the center between January 1981 and December 2006 and receiving the same treatment schedule (multiple injections/insulin pump; regular/lispro insulin) since before pregnancy until delivery. Outcome variables: macrosomia (birthweight >=4000g), large for gestational age newborn (LGA, >P90 of national growth charts). Potential predictors: maternal anthropometric variables, smoking habit, obstetric history (prior pregnancies, macrosomia, poor obstetric history), maternal hypertension, fetal sex, delivery-related variables (gestational age, calendar year and number of pregnancies in that year) and diabetes-related variables (duration, treatment, microangiopathic complications, prepregnancy care and mean blood glucose, insulin requirements (IR, IU/kg/d) and glycated haemoglobin in 1st, 2nd and 3rd trimesters of pregnancy). Statistics: Logistic regression analyses were performed (backward method) with macrosomia and LGA as outcome variables and all aforementioned variables as potential predictors.
Results: 315 consecutive pregnancies fulfilling entry criteria were included. The rate of macrosomia was 13.3% and that of LGA 38.6%. In the prediction model of LGA, 9 predictors were identified including 3 diabetes-related variables (1st trimester IR (OR 72.4, CI 2.4, 2208), 3rd trimester IR (0.04, CI 0.001, 1.043) and 3nd trimester HbA1c (2.871, CI 1.438, 5.732)). The prediction model of macrosomia was consistent with that of LGA.
Conclusion: In women with T1DM, maternal IR are potent predictors of excess fetal growth. The association with 3rd trimester IR can be a consequence of fetal siphoning in overgrown babies whereas the association with 1st trimester IR suggests a causal role of maternal insulin.

Pregnancy outcomes in women with type 1 and type 2 diabetes in a polish population
K. Cyganek[1], A. Hebda-Szydło[1], B. Katra[1], I. Janas[1], A. Borodako[1], I. Kaim[2], J. Skupien[3], A. Reron[2], J. Sieradzki[1], M.T. Malecki[1];
[1]Department of Metabolic Disease, Jagielonian University, Medical College, Krakow, Poland, [2]Department of Obstetrics and Perinatology, Jagielonian University, Medical College, Krakow, Poland, [3]Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, USA.

Introduction and aim: The number of pregnant women with type 2 (T2DM) is increasing worldwide. However, the majority of scientific reports on pregestational diabetes is associated with type 1 diabetes (T1DM). The knowledge on pregnancies of T2DM women is still incomplete. The purpose of this observational study was to assess glycemic control and pregnancy outcomes in women with pregestational T2DM and to compare them with T1DM.
Methods: Medical records of 415 consecutive singleton pregnancies in women with pregestational diabetes from 1999 to 2009 were analysed at the Department of Metabolic Diseases, Krakow, Poland. All women were Caucasians. Among them, there were 70 women with T2DM and 345 with T1DM. We compared HbA1c levels as well as selected maternal and foetal outcomes in both groups.
Results: Compared to T1DM, women with T2DM were significantly older (mean 33.1 years±5.2 vs. 27.8±5.0, respectively), heavier before pregnancy (mean weight 80.7 kg±17.8 vs. 64.5±10.1) and had shorter duration of diabetes (mean 3.3 years±3.2 vs. 11.5±7.3); (p=0.00001 for all comparisons). T2DM women less weight gain during pregnancy than T1DM (mean 10.4 years±7.6 vs. 13.8±6.5; p=0.0001), but final body weight before delivery were higher in T2DM group (mean 90.6 years±16.9 vs. 78.2±11.3; p=0.0000). The gestational age of the first visit was higher in T2DM women (mean 11.4 weeks±7.1 vs. 8.6±4.5, respectively; p=0.00001). Nevertheless, they had better glycemic control in the 1st trimester as measured by HbA1c (6.1% ±1.1 vs. 6.9±1.6; p=0.0008). We observed a decrease of HbA1c level in both groups in the 2nd (5.7 % ±0.9 vs. 5.9±0.8) and 3rd trimester (5.6 % ±0.6 vs. 5.8±0.9), the differences in HbA1c were no longer significant. The rate of perinatal mortality (2.9% vs. 3.5%) and major congenital malformations (7.1% vs. 6.1%) as well as the proportion of pregnancies ended by caesarean sections (56.3% vs. 63.9%) were similar in both groups. The birth weight was slightly smaller in T2DM than in T1DM (mean weight 3194.6 g±880 vs. 3419.2±681.3; p=0.04). The rate of babies born before 37 week of pregnancy was comparable in both groups, respectively 12.9% vs.17.1%. We also observed a similar rate of stillbirths in both groups (8.6% vs. 7.0%; p=0.4).
Conclusion: In this large observational study we found similar pregnancy outcomes in women with T1DM and T2DM in a Polish population, despite better glycemic control at the beginning of pregnancy in T2DM.

Pre-pregnancy body mass index and the risk of adverse pregnancy outcome in two thousand type 2 diabetes mellitus Bangladeshi women

S. Jahan[1], M.A. Chowdhury[2], S.H. Habib[3], S. Saha[3];
[1]Department of Gynaecology & Obstetrics, BIRDEM, , [2]Department of Cardiology, BSMMU, [3]Health Economics Unit, BADAS, Dhaka, Bangladesh.

Background and aims: Obesity before pregnancy is associated with an increased risk of late fetal death, early neonatal death, preeclampsia & hypertensive disorders, preterm delivery, shoulder dystocia & macrosomia. The mother's being leaner than average on the other hand, is associated with an increased risk of delivering an infant of small for gestational age (SGA). The study was undertaken to assess the effect of the pre-pregnancy body mass index (BMI) on maternal & fetal outcome of 2000 type 2 diabetes singleton pregnant women who attended the obstetrics-diabetology Out-Patient clinic of a tertiary care hospital in Bangladesh.
Materials and methods: The women were categorized according to their BMI (kg/m^2): lean < 20.0, normal from 20.0 to 24.9 and obese > 30.0 kg/m^2. Information regarding maternal age, parity, complications during pregnancy or delivery and perinatal outcomes were obtained from hospital records. Late fetal death was defined as still birth occurring at 28 or more completed weeks of gestation and early neonatal death as death occurring during the first week after birth, preterm delivery was less than 37 completed weeks of gestation. SGA infants were defined as the birth weight more than 2SD below the mean birth weight for gestational age. Gestational age was estimated as based on ultrasound examination performed routinely at less than 12 weeks of gestation. The estimates were adjusted for maternal age, parity, smoking, education, and weight gain during pregnancy. The effect of pre-pregnancy BMI was analyzed by comparing the frequencies of various outcomes in three BMI groups by both univariate and multivariate logistic regression analysis. The results were expressed as odds ratio (ORs) and the corresponding 95% confidence intervals (CIs) & p values.
Results: The mean±SD age of the study subjects were 34±5 years, the median (range) duration of diabetes was 4 (3-5) years. The risk of late fetal death was consistently increasing with BMI (ORs were 1.2 (0.9-1.7), 1.6 (1.1-2.3) & 2.6 (1.7-3.8) for lean, normal & obese respectively). The risk of early neonatal death was also higher among women with higher BMI (ORs was 1.6 (1.1-2.3) for obese) (p<0.001). The rate of preeclampsia increased with increasing BMI (the values were 1.8%, 2.5% & 7.0% for lean, normal & obese respectively). Hypertensive disorders was also more common among obese (4.6%) compared with lean (1.3%) and normal (2.6%) (ORs 3.8 (2.5-5.6), 1.6 (1.1-2.2) & 2.5(1.7-3.5) respectively). The risk of preterm delivery was significantly increased for obese group (4.2%), as compare to lean (2.2%) & normal weight (2.4%) (ORs 1.6 (1.3-2.1), 1 (0.8-1.6) & 1.2 (0.9-1.6) respectively) (p<0.001). The risk of SGA was significantly more in lean (2.7%) compared to normal weight (1.5%) & obese group (1.9%) (ORs 2.2 (1.7-2.8), 1.2 (0.9-1.5) & 1.0 (0.6-1.3) respectively). The risk of shoulder dystocia & macrosomic baby was higher in obese group.
Conclusion: Pre-pregnancy obesity increases the risk of late fetal death and perinatal mortality. As obesity prevents small for gestation age infant in Type 2 Diabetes subjects, the Type 2 DM lean women were advised to take adequate diet to meet the basic requirements of pregnancy. On the contrary obese women should reduce the body weight before pregnancy.

1073

What is determined by impaired cardiac function in pregnancy with gestational, types 1 and 2 diabetes mellitus: maternal or neonatal prognosis7

V.A. Petrukhin, S.R. Mravyan, F.F. Burumkulova, T.S. Kovalenko, A.N. Aksenov, A.F. Bashakin;
First obstetric clinic, Moscow regional institute of obstetrics and gynecology, Moscow, Russian Federation.

Background and aims: Cardiac autonomic neuropathy is a common dysfunction in manifest diabetes mellitus (DM) and is proportional to the duration of diabetes and/or a poor glycaemic control. Heart rate variability (HRV) reflects autonomic heart function. The aim of the present study was to investigate whether in pregnant women with prior gestational DM (GDM), insulin-dependent DM (IDDM) and insulin-independent DM (IIDM) alterations of cardiac autonomic function can be observed at the 37-39 weeks of gestation in relation to maternal or neonatal prognosis.
Methods: Fifty four women (10 with GDM - group 1, 17 with IIDM - group 2, 13 with IDDM until 5 years duration - group 3, 7 with IDDM from six to fifteen years duration - group 4 and 7 with IDDM more, than sixteen years duration - group 5) underwent 24-h Holter monitoring at the 37-39 weeks of gestation and 3-6 days postpartum. Heart rate variability (HRV) measures derived from 24-hour electrocardiography monitoring, calculated in the time (standard deviation of all normal RR intervals (SDNN), standard deviation of 5-minute RR intervals (SDANN), root-mean-square of difference of successive RR intervals (rMSSD), and percentage of adjacent RR intervals >50 ms different (pNN50) and frequency domain (total power - TP, power within low-frequency band - LF, and power within high-frequency band - HF).
Results: In group 3 HRV was higher: SDNN was 122,4±24,4ms vs 86,0±34,3ms in GDM; 110,7±60,5ms in group 2; 104,5±40,6ms in group 4 and 50,2±6,7ms (p<0,05) in group 5 respectively. HRV patients of groups 2 and 4 were characterized by wide dispersion of HRV, which reflected from other diseases (hypertension, preeclampsia etc). In type 1 diabetes mellitus HRV progressively declines with duration of illness. Extremely low activity of sympatic nervous system (SDANN less than 68ms) in the 5 group was connected with lower Apgar score, but in common with higher parasympathic activity (rMSSD more than 45 ms) - with poor neonatal and maternal prognosis. After delivery there were no observed restoration HRV to normal in women with diabetes type 1.
Conclusion: The loss of the variability of the cardiac rhythm confirms that in women with IDDM has a chaos in cardiac pacing, which reflects autonomic neuropathy and other complications. In type IDDM neonatal prognosis correlates with maternal activity of sympatric nervous system.

Hypertension and end stage renal disease in women with a past history of gestational hypertension

K. Jahan[1], F. Jebunnesa[2], S. Sultana[2], H. Chowdhury[2], N. Sultana[2], L. Ali[2];
[1]Obstetrics and Gynecology, DMC, [2]Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Insulin resistance is thought to be a converging point in the pathophysiology of GH and it is postulated that women with this disorder have a much higher chance of developing hypertension and end stage renal disease (ESRD) at a later period after delivery. Prospective studies on this issue, however, are still limited. The aim of the present study was to investigate the long-term effect of GH on the postpartum development of hypertension and ESRD.
Materials and methods: The study design had both a cross- sectional and retrospective component. A total of 140 women [age in years 32.4±8.1(yrs) and BMI 25.1±4.1(kg/m^2, m±SD)] with a previous history of GH in any pregnancy were included. Clinical and anthropometric parameters were measured by standard techniques, lipids were measured by enzymetic colorimetric method, urinary total protein by pyrogallol red method, urinary protein by strip method and serum urinary creatinine were measured by alkaline picrate method. Systolic blood pressure 130 mmHg or diastolic blood pressure 90mmHg were taken as cut-off values for hypertension and urinary protein >35mg/dl was the marker for ESRD.
Results: Out of the 140 subjects 49 (35%) developed hypertension and 46 (32.9%) developed ESRD over duration of 5 to 12 yrs. 45(32%) of the subjects had both the complications. The hypertensive subjects had higher age (years, m±SD, 35.8±9.7 vs 30.5±6.4, p=0.001), BMI (kg/m^2 , 26.09±4.3 vs 24.6±3.9; p=0.045), uric acid (mg/dl, 7.38±1.1 vs 4.6±1.6; p=<0.001) and total protein (mg/dl, 47.7±13.5 vs 15.5±5.4; p=<0.001). On logistic regression analysis, hypertension showed a strong positive association with uric acid and total protein when the effects of age and BMI were adjusted. On the other hand ESRD showed strong positive association with uric acid when the effects of age, BMI, fasting blood sugar and Triglyceride were adjusted.
Conclusion: Women with history of GH has a high probability of developing hypertension and ESRD in postpartum life, and both the conditions seem to have association with uric acid as a risk factor.

ATLANTIC DIP: persistent postpartum glucose intolerance in women with previous gestational diabetes along the Irish Atlantic seaboard

M.W. O'Reilly, G. Avalos, M.C. Dennedy, E.P. O'Sullivan, F. Dunne;
Endocrinology/Diabetes Mellitus, University College Hospital, Galway, Ireland.

Background and aims: Gestational diabetes / Impaired Glucose Tolerance (GDM/IGT) is associated with adverse fetal and maternal outcomes. It also identifies women at risk of developing IGT and Type 2 diabetes (T2DM) later in life and in the postpartum period. Up to date prospective figures are not available for persistent glucose intolerance postpartum in the Irish population.
Materials and methods: We compared 357 women with abnormal (GDM/IGT) and 137 women with normal (NGT) glucose tolerance in pregnancy identified by 75g oral glucose tolerance test (OGTT) at 24-28 weeks gestation. This was repeated post partum to reassess glucose tolerance. Logistic regression analysis was used to identify maternal factors that increased the risk of persistent glucose intolerance.
Results: 494 women were tested. OGTT results were classified as NGT (FPG<5.6mmol/l; 2h<7.8mmol/l) or abnormal (IFG; 5.6-6.9, IGT; 2h 7.8-11.0, IFG+IGT; T2DM FPG≥7 ± 2h≥11.1). 2 of 137 (1.4%) women with NGT in pregnancy had abnormal glucose tolerance postpartum. 54 of 357 (15.1%) women with abnormal glucose tolerance (GDM/IGT) in pregnancy remained glucose intolerant post partum. Risk factors for persistent glucose intolerance were family history of T2DM (OR 2.92, 95% CI 1.15-7.41, P=0.02), insulin use in pregnancy (OR 3.65, 95% CI 1.41-9.45,P=0.007). Fasting plasma glucose in pregnancy of 5.6-6.9mmol/l (OR 3.73, 95% CI 1.25-11.09, P=0.01) and ≥7(OR 16.89, 95% CI 3.31-86.02, P<0.001) were strong predictors of postpartum dysglycaemia. Age, BMI, ethnicity did not predict persistent dysglycaemia.
Conclusion: Along the Irish Atlantic seaboard the prevalence of persistent glucose intolerance in women with GDM/IGT in pregnancy is 15.1% compared to 1.4% in control women. This high prevalence suggests a robust follow up programme is necessary for early identification and intervention.

Pregnancy and postpartum glucose status

Pregnancy glucose status	Postpartum glucose status				
	Normal	**IFG**	**IGT**	**IFG+IGT**	**T2DM**
Normal (n=137)	135 (98.5%)	1 (0.7%)	0	1 (0.7%)	0
IGT (n=263)	237 (90.1%)	14 (5.3%)	5 (1.9%)	4 (1.5%)	3 (1.1%)
GDM (n=94)	66 (70.2%)	7 (7.45%)	5 (5.3%)	10 (10.6%)	6 (6.4%)
Total (n=494)	438	22	10	15	9

Perinatal outcome in women with gestational diabetes mellitus in relation with fetal sex

D. Tundidor[1], A. García-Patterson[1], M. María[1], J. Úbeda[1], G. Ginovart[2], J.M. Adelantado[3], A. de Leiva[1], R. Corcoy[1];
[1]Endocrinology and Nutrition, [2]Pediatrics, [3]Obstetrics and Gynaecology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Background and aims: Male sex is a well-known risk factor for unfavorable perinatal outcome that has only occasionally been assessed in diabetic pregnancy. The aim of this study was to evaluate perinatal outcome in women with gestational diabetes mellitus (GDM) according to fetal sex.
Materials and methods: Database review including all singleton pregnancies of women with GDM progressing to >= 22 weeks, delivering in the center between 01/01/1981 and 31/12/2006. Evaluated maternal characteristics: anthropometrics, obstetric history, diagnosis characteristics (gestational age, blood glucose values), HbA1c (after diagnosis and in the third trimester). Outcome variables: preterm birth, abnormal Apgar, large and small for gestational age newborns, obstetric trauma, major and minor malformations, polycythemia, neonatal hypoglycemia, hypocalcemia, jaundice, respiratory distress and fetal loss (intrauterine, neonatal, perinatal). Statistics: Chi-square, Student T and Mann-Whitney U tests. Significance was set at a two-sided p <0.05.
Results: A total of 2216 pregnancies were included. Maternal characteristics did not differ between groups except for a higher maternal weight in male newborns (59 vs. 58) and a higher rate of prior pregnancy in female newborns (65.5 vs. 61.1%). Higher figures were observed in 13 out of 15 perinatal outcome variables in male newborns but statistical significance was not reached in any of them.
Conclusion: In this group of women with GDM, perinatal outcome is not significantly worse in male newborns.

Prevalence and outcome of gestational diabetes in Turkmenistan

K.G. Parhofer[1], A. Ulugberdiyeva[2], M. Abdullayeva[2], A. Annamuhammedov[3], M. Gaipov[4], B. Melebayeva[2], U. Hasbargen[5], A.W. Flemmer[6];
[1]Medizinische Klinik II - Grosshadern, Klinikum der Universitaet Muenchen, Germany, [2]Department of Gynecology and Obstetrics, Ene Maehri Merkezi, Ashgabat, Turkmenistan, [3]Department of Pediatrics, Ene Maehri Merkezi, Ashgabat, Turkmenistan, [4]Department of Anesthesiology, Ene Maehri Merkezi, Ashgabat, Turkmenistan, [5]Department of Gynecology and Obstetrics, Perinatal Center, Klinikum der Universitaet Muenchen, Germany, [6]Division of Neonatology, Childrens Hospital, Perinatal Center, Klinikum der Universitaet Muenchen, Germany.

Background and aims: Very few data are available about the health care system in Turkmenistan a central Asian country with huge gas resources and rapidly increasing wealth and rates of obesity. As for other central Asian countries the prevalence of gestational diabetes (GDM) is unknown. The aim of this investigation was to prospectively determine the prevalence of GDM in Turkmenistan and the frequency of complications in newborns from GDM mothers.
Materials and methods: From March 2008 until September 2009 all pregnant women presenting to the perinatal center at the Ene Maehri Merkezi Hospital (University of Ashgabat) obtained a glucose screening (after 26 weeks of pregnancy; 50 g glucose orally). If the 60-min glucose concentration was ≥ 7.8 mmol/l an oral glucose tolerance test (75 gr) was performed. GDM was diagnosed if one or more glucose values were abnormal (≥5.0, ≥10.0, ≥8.0 mmol/l at 0-, 60-, 120-min, respectively). Birth weight, APGAR and 30 min glucose concentration was determined in all newborns.
Results: 25.4% of 1271 screened patients had a pathological screening test. Of those, 28.5% had GDM (overall prevalence 7.3%). Screening glucose (60-min) correlated with age (r=0.13; p>0.001), BMI (r=0.12, p<0.001), gravidity (r=0.12, p<0.001) and blood pressure (r=0.06, p=0.03). GDM patients were older (30.2±5.3 years vs. 27.1±4.9 years; p<0.001) and more obese (BMI 27.7±4.9 vs. 26.5±4.5 kg/m^2; p=0.03) than controls. GDM patients obtained more frequently scheduled caesarean sections (12.0% vs. 8.9%, ns) and less frequently emergency caesarean sections (8.8% vs. 13.3%, ns). In newborns delivered after ≥37 weeks gestational age (controls vs. GDM) birth weight (3500±462 vs. 3605±409 g, p=0.06) and APGAR (8.4±1.5 vs. 8.3±1.3, ns) did not differ between both groups but GDM children had more often hypoglycaemia (13.9% vs. 27.3%, p<0.05).

Conclusion: In Turkmenistan GDM is characterized by the same risk factors as in European countries. Because of the rapidly increasing wealth and increasing prevalence of obesity the prevalence of GDM will probably further increase. Newborns from GDM patients tended to be heavier and had high rates of hypoglycemia. This study shows that medical prevention programs can also be successfully implemented in Turkmenistan.

1078

Analysis of pregnancy outcomes in immigrate women with gestational diabetes

M. Dalfrà[1], E. Ragazzi[2], M. Masin[1], B. Bonsembiante[1], C. Cosma[1], A. Barison[1], R. Toniato[1], D. Fedele[1], A. Lapolla[1];
[1]Medical and Surgical Sciences, [2]Pharmacology and anaesthesiology, University of Padova, Italy.

Background and aims: Immigration is growing in all European countries, the populations diversity poses specific problems related to health care service and socio-demographic factors. Recent studies show adverse outcomes of pregnancy among immigrant women from countries with high diabetes rates. So we found of interest to analyse the outcomes in immigrate pregnant women affected by GDM compared to Italian ones.
Materials and methods: We compared maternal and fetal outcomes in 94 immigrant (ImPW) and1246 Italian women (IPW) with GDM followed up at our center. Maternal characteristics considered were age, pre-pregnancy BMI, HbA1c, frequency of insulin treatment, timing and mode of delivery, and hypertensive disorders; and, for fetal outcome, infants large(LGA) or small(SGA) for gestational age and fetal complications.
Results: Pre-pregnancy BMI (26.9 ± 4.6 Kg/m^2 vs 24.8 ± 5.3 Kg/m^2, p<0.0001) and HbA1c (at diagnosis and at 3rd trimester 5.6 ± 0.6% vs 5.2 ± 0.6%, p<0.0001) were higher in ImPW than in IPW, and more of them were on insulin (26.6% vs 17%, p=0.024).Gestational age at screening was not different: 23.6±5.8g.w. in ImPW vs 24.6±5.4 g.w. in IPW No differences in time and mode of delivery(cesarean section 46.1% in immigrate women vs 42.9% in Italian ones) and hypertensive disorders (6.8% vs 8.8%) emerged between the 2 groups. A higher rate of LGA babies (30.3% vs 19.8%, p=0.03) were born to immigrant women than to Italians, but fetal morbidity was not different (4.2% vs 6.5%).In a regression logistic analysis LGA newborns were related to maternal age (p=0.002) and HbA1c at 3rd trimester.
Conclusion: Our ImPW show higher glucose levels during pregnancy, but their outcome could be considered satisfied and comparable with IWP, probably because these women were subjected to GDM screening, diagnosis and treatment at the recommended gestational age . So immigrant GDM women have favorable outcomes if given access to health care, language and cultural barriers are removed.

1079

HbA_{1c} above normal range in late pregnancy is associated with risk of infants' large-for-gestational age in women with gestational diabetes mellitus

S.B. Nielsen, M.R. Mikkelsen, E. Stage, E.R. Mathiesen, P. Damm;
Departments of Endocrinology and Obstetrics, Rigshospitalet, Copenhagen, Denmark.

Background and aims: HbA_{1c} is widely used as a measure of metabolic control during pregnancy and documented to be associated with diabetes related pregnancy complications in type 1 diabetes. In addition HbA_{1c} can be measured independent of the patients' compliance to glucose monitoring and is therefore of special value in women where the compliance to treatment is sub optimal. The value of using HbA_{1c} as a treatment goal and risk marker of complications in the newborns of women with GDM is to our knowledge not previously described in the literature. The aims of the present study were 1) to determine the prevalence of pregnant women with gestational diabetes mellitus (GDM) not obtaining HbA_{1c} within normal range before delivery and 2) examine whether elevated HbA_{1c} values are associated with increased risk of large-for-gestational age (LGA) infants.
Materials and methods: The study population was 148 GDM women delivering during 2007 at Rigshospitalet. Inclusion criteria; GDM diagnosed <34 weeks, singleton pregnancies and at least two HbA_{1c} test with more than 3 weeks interval. Data was extracted from medical records. The study population was divided in those obtaining HbA_{1c} less than or equal to 5.6% or not. The primary outcome was LGA infants. Secondary outcomes were preeclampsia, preterm delivery, birth complications, neonatal hypoglycaemia, respiratory distress syndrome and jaundice.
Results: Fifty-one (35%) women did not obtain HbA_{1c} less than or equal to 5.6% before delivery. The median HbA_{1c} before delivery was 5.9% (range 5.7-6.6) vs. 5.3% (4.5-5.6) in the two groups. At baseline, BMI and HbA_{1c} were higher in the women not obtaining the goal compared to the remaining women (30.9 (SD6) vs. 27.8 (SD7); 5.9% (5.7-7.8) vs. 5.1% (4.3-6.3)). Women with elevated HbA_{1c} before delivery were characterised by a higher risk of LGA infants and neonatal hypoglycaemia (adjusted OR 3.1 (95% CI 1.3-7.6), and 6.2 (95% CI 1.3-29.0)). Other secondary outcomes were similar in the two groups.
Conclusion: Women with GDM not obtaining HbA_{1c} within normal range before delivery had a three-fold increased risk of LGA infants and six-fold increased risk of neonatal hypoglycaemia.

1080

The prevalence of large for gestational age offspring and pregnancy complications before and after implementation of a new insulin treatment guideline in women with gestational diabetes

M.R. Mikkelsen, S.B. Nielsen, E. Stage, N. Begum, P. Damm, E.R. Mathiesen;
Departments of Endocrinology and Obstetrics, Rigshospitalet, Copenhagen, Denmark.

Background and aims: The best strategy for insulin treatment of women with gestational diabetes (GDM) under routine conditions is not well described. In 2008 we decided to change from biphasic human insulin (Mixtard) to biphasic insulin aspart (Novomix), which has a better impact on postprandial glucose levels, and furthermore to implement a written algorithm for initiating and adjusting insulin dose. Thus the aim of our study was to evaluate the effect of this change in the routine insulin treatment guideline on birth weight and the prevalence of pregnancy related complications.
Materials and methods: The study population included all insulin treated women with GDM delivering in 2007 and 2009 at our hospital fulfilling the following inclusion criteria; GDM diagnosed and insulin treatment initiated < 34 weeks with the first HbA_{1c} below 6.5%, singleton pregnancies and at least two HbA_{1c} tests with ≥3 weeks' interval. Data was extracted from medical records. The insulin treatment was initiated and adjusted by a nurse the first 14 days and thereafter by an endocrinologist. The 2007-cohort received biphasic human insulin twice daily with individual start dose and adjustments while biphasic insulin aspart was initiated in the 2009-cohort with 0.3 IU /kg twice daily and thereafter adjusted according to a written titration guideline. The primary study outcome was the prevalence of large for gestational age (LGA) infants. Secondary outcome was a combined endpoint of pregnancy related complications including at least one of the following: preeclampsia, preterm delivery, birth complications, neonatal hypoglycaemia, respiratory distress syndrome and jaundice.
Results: The two cohorts were comparable with regard to baseline HbA_{1c} and HbA_{1c} prior to delivery (table). The total insulin dose was comparable, but the second cohort was diagnosed and initiated insulin treatment on average 10 days earlier and tended to be less overweight (NS). In the 2009-cohort offspring birth weight was significantly lower, evaluated by the Z-score as well as the prevalence of LGA. Moreover less pregnancy related complications were seen in the 2009-cohort (table).
Conclusion: The prevalence of large for gestational age infants and pregnancy related complications were lower after implementation of the new insulin treatment guideline as part of routine treatment. Whether this is due to the change in insulin treatment or other factors, as earlier initiation of treatment, remains speculative.

Clinical parameters before and after change in insulin treatment

	2007-cohort n=54	2009-cohort n=47
Pre-pregnancy BMI (kg/m^2)	31.5(7)	29.6(7)
Gestational age at GDM diagnosis(days)	190(43)	180(51)
HbA_{1c} at diagnosis of GDM (%)	5.7(0.4)	5.8(0.3)
Gestational age at delivery (days)	267(9)	269(8)
HbA_{1c}; last before delivery (%)	5.8(0.4)	5.8(0.4)
Insulin dose; last before delivery (IU)	52(40)	49(36)
Birth weight (g)	3516(441)	3297(491)*
Birth weight z-score (standard deviations)	0.8(1.4)	0.1(1.3)**
Large for gestational age	20(39%)	8(16%)*
Pregnancy related complication	20(37%)	9(19%)*

Major congenital malformations in women with gestational diabetes mellitus: a systematic review and meta-analysis

M. Balsells[1], A. García-Patterson[2], I. Gich[3], R. Corcoy[2];
[1]Servei d'Endocrinologia i Nutrició, Hospital Mútua de Terrassa, [2]Servei d'Endocrinologia i Nutrició, Hospital de la Santa Creu i Sant Pau, Barcelona, [3]Servei d'Epidemiologia Clinica, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Background: Gestational diabetes mellitus (GDM) has been associated with a higher rate of congenital malformations, but the association is not universally accepted.
Aim: To perform a systematic review and meta-analysis on major congenital malformations (MCM) in GDM.
Methods: A MEDLINE search using the terms ((malformation OR outcome) AND (gestational diabetes) AND pregnancy)) was performed, limiting the search to the period January 2000 to December 2009. Selection criteria: 1) GDM and control populations are not openly biased; 2) Paper contains information on MCM in women with GDM and in the reference population; data on MCM in pregestational DM was not an inclusion criteria, but if included in the paper, information was recorded. Statistical analysis: Revman 5.0, with a fixed effect analysis method for meta-analysis.
Results: 1924 abstracts were retrieved, 108 full-text articles were revised and finally 9 cohort observational studies and 2 case control studies were included. In women with GDM, cohort studies displayed a high heterogeneity, precluding meta-analysis; in case-control studies, they had a higher rate of MCM (OR 1.40, CI95 1.22-1.62) in relation with the reference group. Women with pregestational DM had a higher rate of MCM vs reference group in both cohort (RR 2.34, CI95 2.02, 2.70) and case-control studies (OR 4.57, CI95 3.01, 6.95).
Conclusion: Infants of GDM mothers have a slightly higher increased risk of MCM, lower than that of women with pregestational DM.

Peripartum and gestational factors influencing neonatal hypoglycaemia in gestational diabetes: a prospective study

J.A. Flores-Le Roux[1], D. Benaiges[1], E. Sagarra[1], E. Hernandez-Rivas[1], M.A. Lopez-Vilchez[2], A. Mur[2], J. Puig De Dou[1], C. Claret[1], A. Goday[1], J.F. Cano[1];
[1]Endocrinology, [2]Pediatrics, Hospital del Mar, Barcelona, Spain.

Background: Most studies on neonatal hypoglycemia in GDM women only take into consideration gestational and neonatal parameters whereas the possible influence of peripartum factors hasn't been fully explored.
Objective: To evaluate peripartum, gestational and maternal factors influencing the development of neonatal hypoglycemia in infants of women with gestational diabetes.
Study design: Prospective observational study including all infants of GDM mothers born at our institution between October 2006 and February 2010. Data collected include maternal characteristics, gestational parameters (GDM treatment, weight gain, HbA1c), peripartum glycemic control (maternal capillary blood glucose (CBG) ketonemia, use of insulin) and CBG measurements in the newborn during the first 24 hours of life.
Results: A total of 183 infants were included with a mean weight of 3353 ± 505 grams and a gestational age of 39.2 ± 1.4 weeks. 30 newborns (16.4%) presented at least one CBG of less than 40mg/dl during the first 24 hours of life. The main maternal, gestational and peripartum characteristics in newborns with or without neonatal hypoglycemia are presented in Table 1. There were no significant differences between hypoglycemic and euglycemic infants in terms of neonatal weight, apgar scores at 5 and 10 minutes, umbilical cord artery and vein pH nor in the rate of small for gestational age. Macrosomia was more frequent in hypoglycemic newborns (21.2% vs 8%, p=0.024). Regarding maternal characteristics, Latin-American mothers were more likely to have infants with hypoglycemia than caucasian mothers (37% vs 17%, p=0.03). No significant differences were observed between other ethnicities (Pakistani, Moroccan, Asian).
Conclusions: Neonatal hypoglycemia does not seem to be influenced by glycemic control during labour. Other factors, such as ethnicity (latin-americans), insulin use during pregnancy and macrosomia, associate an increased risk for neonatal hypoglycemia.

Gestational and peripartum characteristics according to neonatal hypoglycemia

	Newborn CBG≥40mg/dl (n=153)	Newborn CBG<40mg/dl (n=30)	p value
Age (years), mean (SD)	32.7 (5.6)	33.3 (5.9)	0.572
Previous BMI (kg/m2) mean (SD)	27.1 (5.5)	26.2 (4.1)	0.417
Pregnancy weight gain (kg). mean (SD)	9.1 (4.2)	8.8 (2.7)	0.673
GDM treatment: diet/insulin (n/n)	84/44	11/14	0.041
Gestational age (week) mean (SD)	39.2 (1.4)	38.9 (1.4)	0.119
Preterm delivery, n (%)	6 (3.9)	3 (10)	0.167
Intrapartum mean maternal CBG, mean (SD)	99.7 (22.4)	94.9 (15.1)	0.269
Intrapartum maternal CBG> 130mg/dl n (%)	21 (13.7)	7 (23.3)	0.177
Intrapartum Ketosis, n (%)	20 (16.1)	2 (8)	0.372
Intrapartum insulin use, n (SD)	14 (9.2)	4 (13.3)	0.503

1083

In gestational diabetes mellitus, pregestational body mass index is an independent predictor of neonatal hypoglycaemia

A. García-Patterson[1], A. Aulinas[1], M.A. María[1], J. Úbeda[1], I. Orellana[1], J.M. Adelantado[2], G. Ginovart[3], A. de Leiva[1], R. Corcoy[1];
[1]Servei d'Endocrinologia i Nutrició, [2]Servei d'Obstetricia, [3]Servei de Pediatria, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Background: Recently published data from the HAPO study reveal pregestational body mass index (BMI) as a predictor of cord blood C peptide; significance was not reached for the prediction of neonatal hypoglycemia (NH).
Aim: To assess pregestational BMI as a predictor of NH in women with gestational diabetes mellitus (GDM).
Methods: Database review of all GDM pregnancies (singleton and twins) attended in the Diabetes and Pregnancy Clinic of the center from 1st January 1981 to 31st December 2006. Outcome variable: NH defined as capillary blood glucose fulfilling Cornblath cut-off criteria in >=2 occasions in the first 48h of life. Screening for GDM was universal and used O'Sullivan test; diagnosis used NDDG criteria. We considered the following as potential predictors of NH: age, weight, height, BMI, weight increase during pregnancy, prior poor obstetric outcome, smoking habit, family history of DM, prior GDM/abnormal glucose tolerance, gestational age and glucose values at diagnosis, delay between diagnosis and treatment initiation, capillary blood glucose & HbA1c during pregnancy, insulin treatment, twin pregnancy and newborn sex; as potentially intermediate variables we considered maternal hypertension (chronic/pregnancy-induced), preterm birth, cesarean section, small and large-for gestational age newborns, abnormal Apgar and respiratory distress. Statistical analysis: bivariate analyses comparing characteristics of pregnancies with and without NH; logistic regression analysis (backward method) with NH as the dependent variable and aforementioned variables as potential predictors.
Results: During the study period, 2492 newborns of mothers with GDM were delivered (2228 singleton) and NH was observed in 3% of them. Mothers of NH newborns differed in a number of characteristics, one of them being prepregnancy BMI (24.45 vs 23.19 kg/m2, p <0.02). Logistic regression analysis identified pregestational BMI as a predictor of NH both when potentially intermediate variables were included (OR 1.293, CI 1.007, 1.660) or not (OR 1.359, CI 1.073, 1.721).
Conclusion: Pregestational BMI is an independent predictor of NH in this cohort of women with GDM.

Intensive glycaemic control in type 1 diabetic pregnancy: a comparison of continuous subcutaneous insulin infusion and multiple daily injection therapy

K. Neff[1], A. McCarthy[1], R. Forde[1], M. Foley[2], S. Coulter-Smith[3], S. Daly[4], R. Firth[1], M.M. Byrne[1], B.T. Kinsley[1];
[1]Mater Misericordiae University Hospital, [2]National Maternity Hospital, [3]Rotunda Maternity Hospital, [4]Coombe Womens and Infants Hospital, Dublin, Ireland.

Background and aims: Continuous subcutaneous insulin infusion (CSII) has been used in pregnancy and to date is thought to be non-inferior to a multiple daily injection (MDI) regimen. We reviewed a cohort of pregnant patients with type 1 diabetes mellitus (T1DM), and compared a cohort on CSII with a cohort treated with MDI, with the aim of assessing any difference in glycaemic control and pregnancy outcomes.
Materials and methods: We reviewed 507 women with TIDM who presented for antenatal care with our service over a 5-year period. There were 46 women treated with CSII and 461 treated with MDI. All subjects were asked to maintain daily 7-point profiles and these were reviewed weekly. Blood glucose measurement (BGM) targets were 5mmol/l or less pre-meals and 7mmol/l at one hour post-prandial. Maternal parameters including age, parity and weight were recorded. Glycaemic control represented by HbA1c in each trimester, attendance at a pre-pregnancy counseling clinic, and pregnancy outcome including Cesarean section rate, were recorded and differences were compared with Students' t-test and an odds ratio where appropriate.
Results: Women on CSII were older (35 ± 4 years Vs 31 ± 5 years, p<0.001), and booked earlier (6 weeks ± 2 Vs 8 weeks ± 5, p<0.05) to ante-natal diabetes care. Women treated with CSII had lower HbA1c levels at booking (6.5% ± 0.8 Vs 7.8% ± 1.4, p<0.001) and delivery (5.9% ± 0.3 Vs 6.3% ± 0.6, p<0.05). Cesarean section was recorded at a higher rate in those on CSII (67% Vs 46%, p<0.05). Birth weight did not differ between groups (3.6kg ± 0.6 Vs 3.5kg ± 0.8). There was no significant difference in peri-natal mortality between groups. Those treated with CSII were more likely to attend the pre-pregnancy service (40% of all pregnancies Vs 10%, OR 5.8, p<0.001). Women attending the pre-pregnancy service had lower HbA1c values at booking than those who did not attend (6.7% ± 1.4 Vs 7.8% ± 1.5, p<0.001). Patients treated with CSII attending the pre-pregnancy clinic had lower HbA1c values at booking than those treated with MDI (6.5% ± 0.7 Vs 7.0% ± 0.9, p<0.05), but there was no significant difference in HbA1c values at delivery between these two groups (6.3% ± 0.6 Vs 6.2% ± 0.7).
Conclusion: Women treated with CSII were more likely to book earlier to ante-natal services, to have attended pre-pregnancy services, and had better glycemic control than women treated with MDI. Cesarean section rates were higher in women treated with CSII despite similar birth weights at delivery in both groups. Peri-natal outcomes did not differ between groups. In our cohort CSII and MDI are both effective in improving maternal glycaemic control both pre-pregnancy and in pregnancy. CSII achieved lower HBA1c values by delivery. Both CSII and MDI are effective therapies for the management of T1DM in pregnancy.

1085

Conversion of pregnant patients with type 1 diabetes from multiple injection therapy to continuous subcutaneous insulin infusion in early pregnancy is safe and efficacious

M. Shanmugasundaram[1], H. Rogers[1], P. Marks[1], A. Jain[2], M.S. Marsh[2], C. Gayle[1], S.A. Amiel[1], P. Choudhary[1];
[1]Diabetes Research Group, [2]Obstetrics, Kings College Hospital, London, United Kingdom.

Background and aims: Adverse risks to mother and fetus in pregnant type 1 diabetic (T1DM) patients are attributed to poor maternal glycaemic control. Continuous subcutaneous insulin infusion (CSII) has not been proven to improve pregnancy outcome. Initiating CSII in early gestation due to poor glycaemic control or to replace long acting analogues may be associated with risk, as patients learn to use it. This study aimed to compare maternal glycaemic control, obstetric and fetal outcomes in diabetic pregnancies managed with CSII and multiple daily injections (MDI).
Materials and methods: In a retrospective case notes audit of 90 T1DM pregnancies (52 treated with CSII) between 2002 and 2009, we recorded HbA1c pre-conception and in each trimester; fetal ultrasound measurements; mode of delivery; age-corrected birth weight; APGAR scores and admission to neonatal intensive care unit (NICU). Primary comparison was between MDI and CSII. Secondary comparisons were between groups: CSII pre- (n=20) and post- (n=32) conception, MDI HbA1c <7.5% in trimester 1 (n=20) and MDI HbA1c >7.5% in trimester 1 (n=18). We compared MDI >7.5% with those converted to CSII due to poor control (n=8).
Results: CSII and MDI patients were comparable for age (31.9± 5.58 vs 29.9± 6.13 yrs p=0.1) and BMI (26.4± 4.04 vs 27.9± 5.92 yrs, p=0.2). CSII users were 84.6% Caucasian (vs 57.9% MDI, p=0.005), with longer diabetes duration (17.0± 7.05 vs 10.7± 7.98 yrs, p<0.001). CSII group achieved lower HbA1c in trimester 1 (7.0± 1.0 vs 7.6± 1.7%; p=0.03) and 2 (6.3± 0.7 vs. 6.8± 1.5%; p=0.04), with no significant difference in trimester 3 (6.2± 0.58 vs. 6.4± 1.0 p=0.3). Severe hypoglycaemia rates were not different. Fetal growth velocity was not different. There were more emergency Caesarean sections (42 vs 24% p=0.07) in MDI patients, with no differences in macrosomia, age-corrected birth weight centiles, or NICU admission. There were no differences in outcome between CSII pre-conception and MDI < 7.5%, nor between these groups combined and CSII post- conception. MDI >7.5% had significantly greater HbA1c in all trimesters, lower 5 minute APGAR score and greater NICU admission. Those converted to CSII post- conception due to poor control had lower HbA1c in trimester 1 (8.3± 0.67 vs 9.5± 2.0 p=0.06), 2 (6.9± 0.96 vs 7.8± 1.46 p= 0.15), and 3 (6.7± 0.83 vs 6.9± 1.06 p=0.6), than MDI >7.5%. This CSII converted group had higher 5 minute APGAR score (9.17± 0.76 vs 8.71± 2.08 p=0.09) and less NICU admission (38 vs 56% p=0.6).
Conclusion: Appropriately used, MDI can provide similar pregnancy outcomes to those using CSII for clinical indications. In those with raised HbA1c at booking, or requiring different basal insulin replacement regimens, initiation of CSII in early pregnancy is safe and efficacious leading to improved glycaemic control, and less neonatal intervention requirement.

Comparison between MDI and CSII in type 1 diabetic pregnancies

	MDI		CSII		P-value ANOVA
	HbA1c < 7.5% in trimester 1 (n=20)	HbA1c > 7.5% in trimester 1 (n=18)	Using CSII pre-conception (n=20)	Initiated CSII post-conception (n=32)	
1st trimester HbA1c mean (SD)	6.4 (0.61)	9.1 (1.50)	6.9 (0.80)	7.5 (1.08)	p<0.001
2nd trimester HbA1c mean (SD)	6.0 (0.92)	7.8 (1.45)	6.3 (0.67)	6.2 (0.72)	P<0.001
3rd trimester HbA1c mean (SD)	5.9 (0.61)	7.0 (1.06)	6.3 (0.51)	6.1 (0.63)	P<0.001
Corrected birth weight centiles mean (SD)	63.0 (30.10)	68.8 (36.68)	63.0 (33.75)	77.7 (28.86)	P=0.3

Glycaemic control and pregnancy outcomes in women with type 1 diabetes: a systematic review and meta-analysis comparison between lispro and regular insulin

C. González-Blanco[1], A. Chico[2], I. Gich[3], R. Corcoy[2];
[1]Endocrinology, Eduab-HSP, [2]Endocrinology, Eduab-HSP, [3]Clinical Epidemiology, Hospital Sant Pau, Barcelona, Spain.

Background: There is limited evidence of the influence of insulin lispro (LP) vs regular (RI) on glycemic control and pregnancy outcomes in pregnancies of women with Type 1 diabetes mellitus (T1DM).
Aim: To perform a systematic review and meta-analysis on glycemic control and pregnancy outcomes in women with T1DM treated with insulin LP vs. RI since before pregnancy.
Methods: A Medline and EMBASE search were performed using the terms ((lispro OR Humalog OR (insulin analog) AND pregnancy) without any limit. Abstracts (and full papers when appropriate) were reviewed by two

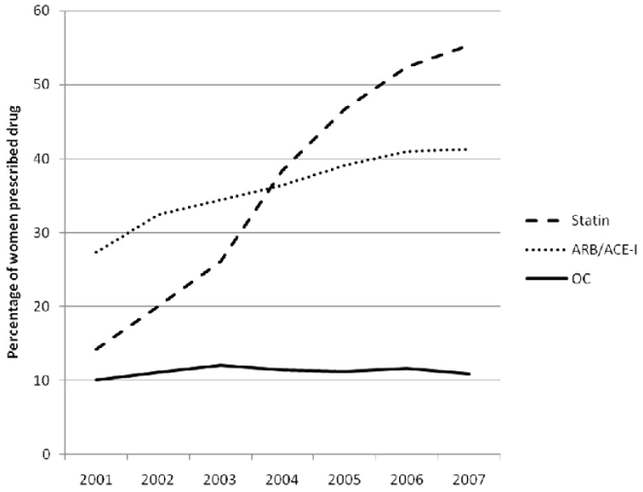
independent researchers and differences set with a third one if needed. Inclusion criteria: T1DM, data on women treated with RI and LP since before pregnancy until delivery in the same paper, minimum number of 5 pregnancies in each group, information on at least one pregnancy outcome. Baseline characteristics, metabolic control during pregnancy and outcome data were extracted using predefined templates. Baseline characteristics were compared without performing a formal statistical analysis and outcome data were summarised with Revman 5.0.
Results: 267 abstracts were identified and 5 papers fulfilled inclusion criteria, all of them corresponding to observational studies. Women treated with LP or RI were similar in terms of age, BMI, diabetes duration, chronic hypertension and pre-pregnancy clinic attendance. Outcome data: HbA_{1c} were lower in patients treated with LP, at the beginning of pregnancy (mean difference (MD) -0.12; CI -0.49,-0.24) and in first (MD -0,33; CI -0.59,-0.08), second (MD -0.51; CI -0.83,-0.2) and third trimesters (MD -0.17;CI -0.38, 0.03). Gestational age at birth (MD 0.41; CI -0.04, 0.87), birthweight (MD 133.68; CI 19.35, 248) and the rate of large for gestational age newborns (LGA) (RR 1.35; CI 1.12-1.61) were higher in the LP group. No differences were observed in the rate of pregnancy induced hypertension, preeclampsia, diabetic ketoacidosis episodes, spontaneous miscarriages, interruptions, total abortions, caesarean section, preterm birth, macrosomia, small for gestational age newborns, stillbirth, neonatal and perinatal mortality, neonatal hypoglycemia and major malformations.
Conclusions: In relation with women with T1DM treated with RI, those treated with LP display similar baseline characteristics, achieve better glycemic control, deliver at a higher gestational age but birthweight and rate of LGA are higher.

1087

Exposure to teratogenic drugs and concomitant contraception in women of child-bearing age with type 2 diabetes: a population based cohort study

D.A. Webster[1], K. Khunti[2], E.G. Wilmot[3], B. Thakrar[4], M.J. Davies[2], A. Anwar[1];
[1]University Hospital Coventry and Warwickshire, Coventry, United Kingdom, [2]University Hospitals of Leicester, United Kingdom, [3]University of Leicester, United Kingdom, [4]PDB Epidemiology, Roche AG, Coventry, Switzerland.

Background and aims: Twenty years after the St. Vincent declaration, pregnancy outcomes remain poor in women with diabetes. Perinatal mortality and congenital anomaly rates are four and two times that of the background population respectively. Preconception care, optimal glycaemic control and folate supplementation are known to reduce pregnancy risk in women with type 2 diabetes (T2DM). Despite this, many women remain poorly prepared for pregnancy and it is often unplanned. Since the introduction of the Pay for Performance in the UK in 2004, there has been more aggressive management of cardiovascular risk in people with diabetes. Some of the medications advocated for primary and secondary prevention of cardiovascular disease are potentially teratogenic. The aim of this longitudinal study was to identify changes in the prescription of cardiovascular medications and contraception for women of childbearing age with T2DM between 2000 and 2007 in the UK.
Materials and methods: Data were extracted from the General Practice Research Database (GPRD) for all women of child bearing age (14-49 years) with T2DM. Data were collected from seven consecutive annual time points between 2000 and 2007 and included details on age, body mass index (BMI), blood pressure, diabetes complications and prescription of statins, ACE-inhibitors, angiotensin-II receptor blockers (ARBs) and oral contraception (OC). Data were analysed in SAS 9.1.
Results: In 2001 the GPRD contained records of 1,195,600 female patients, of whom 1968 (0.16%) were aged 14-49 with T2DM. The study cohort size increased yearly to 5263 in 2007 (0.34% of GPRD female records). The proportion of women in each age group was consistent across the seven year period: 40% of women were aged 45-49 years, 28.5% 40-44 years, 16.5% 35-39 years, 8% 30-34 years, 3.5% 25-29 years, 2% 20-24 years and 1% 14-19 years. Of the 2007 cohort, 40% had an HbA1c >8%, 70% were obese and 27% had hypertension. Retinopathy was recorded in 11%, acute coronary syndrome in 1% and stroke or transient ischaemic attack in 1%. The use of statin therapy increased significantly in these women from 14% in 2001 to 55% in 2007 ($p<0.0001$ for trend) whilst OC use remained around 11% ($p= 0.8$ for trend) (see figure). In 2007, only 9.1% of women on a statin were also prescribed oral contraception.
Conclusion: Women of child bearing age with T2DM represent a high risk group. Despite increasing use of statins, ACE inhibitors and ARBs for primary and secondary prevention, OC prescription remains unchanged. This would suggest many women are at risk of pregnancy despite the prescription of potentially teratogenic drugs, further increasing the risk of poor pregnancy outcome. There is an urgent need to address preconception care in this rapidly expanding cohort of high risk women with T2DM.



1088

Low glycaemic index and hypocaloric diet therapy versus conventional approach in gestational diabetes/one abnormal value in pregnancy, after medical nutritional therapy failure

A. Napoli, C. Festa, G. Merola, M. Bongiovanni, L. Mattei, A. Colatrella; Clinical and Molecular Medicine, 2nd Faculty of Medicine, Sapienza University, Rome, Italy.

Background and aims: We compared the efficacy of a low glycemic index and hypocaloric diet vs a conventional approach by insulin treatment in terms of maternal and fetal outcome, in GDM and OAV after medical nutritional therapy failure.
Materials and methods: Prospective Randomized open-label study (based on math criteria) exploring the two approaches. In 2007-2009, 97 pregnant women (63 GDM; 34 OAV; age 34,86±4,86; BMI 25,23 ±4,93 Kg/m²), were enrolled, at our diabetic and pregnancy unit. At the first visit (27,74± 7,25th gestational week) proper nutritional therapy was prescribed. In 18 women the total daily expenditure was measured by Metabolic Holter Body Media. Women with fasting glycemia ≤105mg/dl and postprandial glycemia ≤160mg/dl were assigned to "conventional medical nutrition therapy" ("A" Diet: about 30 cal/kg: 50-55%CHO; 20% protein; 25-30% lipids); for ethical reasons the women exceeding these cutoff BG levels, were directly treated with insulin injections (group EI). The elegible patients, were randomly shifted to a low glycemic index hypocaloric diet ("B" Diet: about 27 cal/kg: 45% CHO; 20% protein; 35% lipids) or to a classical approach with insulin (group I), when one week later, fasting BG was ≥90mg/dl and/or postprandial BG≥130mg/dl in ≥30% of each time point /week. Then, all the patients were strictly monitored, including daily self-control of ketonuria. Those belonging to group B were further shifted to insulin if the metabolic goals were not reached with low glycemic index and hypocaloric diet. STATISTICS**:** paired and Un-paired ***t***-test and χ^2.
Results: 22 subjects (23,17% of the population) kept being under diet A up the end of pregnancy (age: 34,95± 4,73; BMI 24,86±4 Kg/m²),17 (17,89%) were directly shifted to insulin for ethical reasons (34,4± 5 BMI 26,4 ±3,41 Kg/m²), whilst 30 women were randomized to B and 28 to I. The two groups were matched for the main anthropometric and metabolic indexes. 21 subjects of B (70% of B) achieved the metabolic goals until the delivery (age 35,9 ±4,3; BMI 24,48± 3,63 Kg/m²), whilst 9 needed to add insulin (30% of B) at 26,11±7,66th gestational week (age 33±2,87; BMI 32,42±6,63 Kg/m²). Significant differences were observed between B and BI for BMI ($p=0,003$). All groups are similar for type (CS=49; Spontaneous=37) and week of delivery (38,54± 1,69th gestational week). No differences were found for birth weight among B and I groups, but significant differences were observed between A and I as well between EI and I, with a total of 5 macrosomic births (EI=2; I=1;

A=2). In addiction levels for significance were observed for Ponderal Index ((kg/length m³) comparing A to I. No differences were observed for length (49,77± 2,24cm), APGAR 1' (8,7±0,62), APGAR 5'(9,7± 0,46), n° of hypoglycaemia (tot=5; 2 in EI and 3 in I), n° of hypocalcemia (2 in I).

Table 1. Maternal and fetal outcome

	Weight gain in pregnancy (kg)	Birth Weight (g)	Birth Ponderal Index (kg/m³)
A	12.14±3.87	3434.95±427.86	27,4±3,8
B	8.57±3.68	3209.44±380.75	25,4±2,1
BI	5.87±5.55	3326.66±412.00	27.06±3.03
I	9.63±3.93	3057.27±446.07	25.44±2.10
EI	13.61±6.11	3438.75±543.20	26.17±2.81

Weight gain in pregnancy (kg): A vs I p=0.03; A vs BI p=0.002; B vs EI p=0.003; BI vs EI p=0.006; BI vs I p=0.03; EI vs I p=0.01
Birth Weight (g): A vs I p=0.008; EI vs I p=0.02
Birth Ponderal Index (kg/m³): A vs I p=0.04

Conclusion: A low glycemic index and hypocaloric diet can be safely prescribed since the 1st visit in GDM and OAV.

1089

Effects of moderate physical activity on metabolic control in women with gestational diabetes

A. Ghio[1], A. Bertolotto[1], V. Resi[1], C. Lencioni[1], L. Battini[2], S. Politi[1], M. Corfini[1], S. Del Prato[1], L. Volpe[1], G. Di Cianni[1];
[1]Department of Endocrinology and Metabolism, Section of Diabetes and Metabolic Diseases, [2]Department Maternal-Childish, University Hospital, Pisa, Italy.

Background and aims: Diet and exercise have been shown to be effective tools for prevention and treatment of all metabolic abnormalities. In spite of that, little information is available on the effect of lifestyle on glucose control in women with gestational diabetes (GDM). Therefore, we performed this study to evaluate whether moderate physical activity (PA) may improve metabolic control in women with GDM.
Materials and methods: After stabilization standardized diet based on pre-pregnant BMI, 32 GDM women (age 34.5±4.7 yrs, 31% primiparous, pre-pregnancy BMI 26.7±6.8 kg/m²) were invited to walk 30-min a day four times a week during pregnancy. At the beginning of 27±1 week of gestation, upon collection of anthropometric and metabolic parameters, a sensewear armband (SWA) was applied to all women for a 7-days monitoring of PA's intensity and duration, active energetic output and number of steps. During the same period, diet compliance was evaluated by a food frequency questionnaire and data elaborated using a computerized program (Metadieta®). All women were requested to measure capillary blood glucose 4 times a day during test week (fasting, 1hr after breakfast, after dinner and after lunch). Insulin treatment was allowed at the investigator's discretion.
Results: Study population was arbitrarily divided in active (n=16) and sedentary (n=16) women, based on median level of PA activity. There was no difference in age, parity, pre-pregnant BMI, and weight gain between the two groups. Active women had higher intensity (1.5±0.2 *vs.* 1.2±0.1 mets/day) and duration (102.5±57.2 *vs.* 47±20.4 minutes/day) of PA, greater active energetic output (466±235 *vs.* 244±99 Kcal/day) and higher number of steps (11,764±2,839 *vs.* 7,080±1,840) as compared to sedentary women (all p<0.05). There was no apparent difference in caloric intake (active: 1,895±477 *vs.* sedentary: 2,089±434 Kcal) and diet composition in the two groups (carbohydrates: 47.4±5.5% *vs.* 46.4±6.6%, fat: 35.5±2.5% *vs.* 36.1±2.7, proteins: 18.4±2.3% *vs.* 16.1±23%). No difference was found in blood glucose readings with the exception of lower 1-hr post-breakfast values in active women (5.9±0.8 *vs.* 6.6±0.1 mg/dl; p<0.04). Insulin therapy was deemed necessary in 12.5% of active women as compared to 50% of sedentary women (p<0.05), and when needed insulin requirement was lower in the former (0.1±0.5 *vs.* 0.3±0.2 IU/Kg/day; p<0.05). End-pregnancy HbA1c levels were lower in active than in sedentary women (4.8±0.3 *vs.* 5.5±0.2%; p<0.04). The former also higher serum HDL-cholesterol (77±11 *vs.* 63±14 mg/dl, p=0.006), while no differences were observed in total- and LDL cholesterol as well as triglycerides. The difference in PA had no effect on delivery time, percent of caesarean sections, and newborn health status.
Conclusion: Mild physical activity contribute to improve metabolic control in women with GDM reducing the number of women requiring insulin treatment and reducing insulin dose in those requiring it.

Comparing pregnancy outcomes for intensive versus routine antenatal treatment of gestational diabetes based on a 75gram oral glucose tolerance test 2-hour blood glucose 7.8 - 8.9mmol/l

C. Gayle[1], S. Germain[2], M.S. Marsh[3], D. Rajasingham[2], A. Brackenridge[2], P. Carroll[2], S.A. Amiel[3], S. Thomas[2];
[1]Diabetes and Obstetrics, Kings College Hospital NHS Foundation Trust, London, [2]Diabetes & Obstetrics, Guys and St Thomas' Hospital NHS Foundation Trust, [3]School of Medicine, Kings College London, United Kingdom.

Background and aims: The recent consensus guideline for gestational diabetes, from the HAPO group suggests a diagnostic 75 gram oral glucose tolerance test (OGTT) 2-hour blood glucose (2hr-BG) of 8.5mmol/l. Although HAPO and other trials show adverse outcomes for dysglycaemia in pregnancy, debate continues as to the efficacy of treating gestational diabetes (GDM) when the 2-hour blood glucose (2hr-BG) in the diagnostic 75 gm OGTT lies between 7.8 and 8.9 mmol/l. Our aim was to look at the effect of interventional treatment based on an OGTT 2-hr blood glucose 7.8 - 8.9mmol/l.
Materials and methods: A retrospective study covering 3.5 years between 2005 and 2008 between two clinics in teaching hospitals serving the same local population. Clinic A used, WHO (2-hr BG 7.8 mmol/l) and clinic B used, EASD (2-hr BG 9.0 mmol/l) diagnostic criteria for GDM. We compared the maternal and fetal outcomes for women whose 2-hr BG was between 7.8 and 8.9mmol/l. Clinic A patients were treated as GDM and managed intensively in the diabetes antenatal service and Clinic B were given dietary advice and managed conventionally.
Results: Demographics; women in clinic A N= 79 and Clinic B N=130 were well matched for age (33.2± 5.8 vs 33.1± 4.8 years) and BMI (28.6± 5.5 vs 27.2± 6.4). Values mean± sd. Centres were well matched for ethnic distribution and represented a multi-ethnic population: 39 vs 35% Black African and Caribbean: 14 vs 12% Asian: 47 vs 25% Caucasian and 0 vs 28% not documented. Screening values (mean±sd) showed no statistically significant difference: OGTT 2hr- BG (8.3± 0.32 vs 8.3± 0.34mmol/l) and HbA1c (5.39± 0.53% vs 5.44± 0.48%). Maternal Outcomes: women in clinic A had higher rates of induction (43% vs 21%), similar rates of caeasarian section (CS) (39%); with lower emergency CS rates (35% vs 74%). Fetal outcomes: women in clinic A had earlier gestational age for delivery (38.6± 1.3 vs 39.7± 1.9 weeks P<0.001); lower birthweight (3332± 504 vs 3556± 625grams P<0.05) and lower macrosomia rate (>4Kg 9% vs 25%).
Conclusion: Diagnosis of GDM with a OGTT 2hr-BG 7.8 - 8.9 mmol/l and treatment in a combined diabetes antenatal clinic is worthwhile with a decreased macrosomia rate and fewer emergency CS. There was an increased rate of induction, but no associated increase in CS.

1091

Metformin vs insulin in the treatment of gestational diabetes: impact of maternal pregestational BMI on birth weight and need for additional insulin during metformin

T. Rönnemaa[1], K. Tertti[2], U. Ekblad[2];
[1]Department of Medicine, University of Turku, [2]Department of Obstetrics and Gynecology, University of Turku, Finland.

Background and aims: In the previous MiG trial metformin and insulin treated mothers with gestational diabetes had infants with similar birth weights and rates of macrosomia. It can be hypothesized that with respect to neonatal weight, obese mothers could benefit more than non-obese mothers from metformin treatment vs insulin as metformin is known to induce less maternal weight gain, which in turn associates with fetal growth.
Materials and methods: We analyzed birth weight data from first 150 pregnancies in an ongoing randomized trial comparing metformin and insulin treatment of GDM. (Women with fasting P-glucose > 7.0 mmol/L or postprandial glucose > 11.0 mmol/L were not included in this trial.) In the present study we stratified the mothers by pregestational BMI 30 kg/m2 into obese and non-obese. Seventy-five mothers were included in both treatment groups. Mean maternal age (metformin vs insulin 31.8 vs 32.2 yrs), pregestational BMI (29.6 vs 28.5), glucose values in pretreatment OGTT or gestational weeks at delivery (39.3 vs 39.5 wks) did not differ between the two treatment groups.
Results: Birth weights tended to be higher (3658 g vs 3556 g, p = 0.19) in children of pregestationally obese compared with non-obese mothers (treatment groups combined). Birth weights were similar in metformin and insulin groups irrespective of maternal pregestational BMI. Need for additional insulin, defined as fasting P-glucose with metformin > 5.5 mmol/L and/or postprandial glucose > 7.8 mmol/L, was equally common in obese and non-obese metformin treated mothers. Rates of macrosomia were low in all study groups.

Conclusion: Compared with insulin, metformin is equally effective in the treatment of gestational diabetes in both obese (BMI > 30) and non-obese (BMI < 30) mothers. Additional insulin is needed in ca 20% of metformin treated mothers irrespective of obesity.

Birth weight and macrosomia stratified by treatment group and pregestational BMI

Group	n	additional insulin	birth weight, g	p for birth weight, metfo vs insulin	macrosomia, n (p metfo vs insulin)
Metformin, all	75	19 %	3629	0.41	4 (p=0.37)
Insulin, all	75		3567		1
BMI < 30, metformin	41	20 %	3601	0.35	1
BMI < 30, insulin	48		3519		1
BMI > 30, metformin	34	18 %	3663	0.94	3
BMI > 30, insulin	27		3652		0

Two year's outcomes following the institution of combined ADIPS Guidelines for the management of diabetes in pregnancy

G. Fulcher[1], C. Johnson[2], S. Buchanan[2], W.B. Giles[2];
[1]Endocrinology, [2]Obstetrics and Gynaecology, Royal North Shore Hospital, St Leonards, Australia.

Background and aims: In mid 2007, we reviewed our approach to the management of pregnant women with diabetes following a review of published guidelines. We noted that the recommendations for maternal and fetal monitoring and timing of delivery were not unified. For example North American authors suggest twice weekly non-stress CTG from 28-32 weeks. By contrast the Australian Diabetes in Pregnancy Society (ADIPS) Consensus Document states. Formal testing of fetal wellbeing (eg, cardiotocography, umbilical Doppler blood flow studies or biophysical profile) is not necessary in an otherwise uncomplicated pregnancy before 36 weeks gestation.
Materials and methods: In 2008 we adopted a more conservative approach to obstetric monitoring of diabetic women in pregnancy. This consisted of routine fetal heart rate (FHR) monitoring at 36 weeks and growth ultrasounds at 28, 32 and 36 weeks gestation. Insulin requiring women with unstable control were delivered at 39 weeks and those with optimal control were delivered at 40 weeks. Women with diet controlled gestational diabetes mellitus (GDM) were delivered by 41 weeks. The latter were followed throughout pregnancy in a routine antenatal clinic with review by obstetricians, diabetes educators, and dieticians. The aim of this review was to examine the outcomes of women managed with this approach during 2008 and 2009.
Results: The data are listed in the table 1. The one perinatal mortality was a fetus terminated at 20^{+6} weeks for Trisomy 13. There were fewer caesarean deliveries in those women with diet controlled GDM than in women taking insulin (34% vs. 48% P=0.005), fewer instrumental deliveries (9 vs. 22 P=0.028) and fewer admissions to SCN (1 vs. 16 P<0.001). There were no differences in birth weight, shoulder dystocia, admissions to NICU or 5 minute Apgar scores ≤7.
Conclusions: A more conservative approach in the management of diabetes in pregnancy is associated with good outcomes for a cohort of almost 400 women managed in our unit over a 2-year period. The majority of women in both groups delivered before the need for induction of labour.

Table 1. Pregnancy outcomes of the 390 women with diabetes in pregnancy.. Median±SE (range)

		Diet GDM (N=187)			Insulin Requiring (N=203)	
Delivery (weeks)		39.3 ± 0.21 (20.6-41.5)		39.1 ± 0.15 (24.5-40.6)		P=0.0005
Birth Weight (g)		3240 ± 47 (395-4560)		3325 ± 43 (661-4850)		NS
	Spont Lab (N=112).	Induction (N=50)		Spont Lab. (N=87)	Induction (N=68)	
Delivery (wks)	39.2 ±0.26 (25.5-41.3)	40 ±0.44 (20.6-41.5)	P=0.0027	38.5 ± 0.27 (24.5-40.1)	39.6 ± 0.13 (34.1-40.4)	P<0.001
Birth Weight (g)	3200 ± 67 (685-4560)	3347 ± 92 (395-4238)	P=0.03	3105 ± 69 (661-4390	3422 ± 62 (2020-4730)	P=0.0007

PS 105 Biomarkers in pregnancy

1093

Circulating vaspin levels are increased during pregnancy but shown no association with parameters of insulin sensitivity in women with gestational diabetes

L. Kosi[1], A. Handisurya[2], Y. Winhofer[1], J. Todoric[3], A. Tura[4], K. Klein[5], D. Bancher-Todesca[5], G. Pacini[4], H. Esterbauer[3], A. Kautzky-Willer[1];
[1]Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [2]Department of Internal Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna, Austria, [3]Clinical Institute for Medical and Chemical Laboratory Diagnostics, Medical University of Vienna, Austria, [4]Metabolic Unit, National Research Council, Institute of Biomedical Engineering, Padova, Italy, [5]Department of Obstetrics and Gynecology, Division of Feto-Maternal Medicine, Medical University of Vienna, Austria.

Background and aims: Visceral adipose tissue-derived serpin (Vaspin) is a novel adipokine that might be play a role in glucose metabolism. In humans, circulating vaspin levels were found to be increased in subjects with T2DM and to positively correlate with BMI and parameters of insulin sensitivity. In women with GDM, no differences in serum vaspin levels have been observed. However, acute glucose-induced changes under standardized conditions as well as effects of pregnancy itself on circulating vaspin levels remain to be elucidated.
Materials and methods: Plasma vaspin concentrations were measured in 20 pregnant women (10 GDM and 10 NGT) at 0, 30, 60 and 120 min of a 2h-75g-oral glucose tolerance test (OGTT) during gestational week 21-28 and three months after delivery by a commercially available ELISA kit (human Vaspin ELISA kit, Adipogen, Seoul, South Korea). Fasting insulin sensitivity was estimated by the homeostasis model assessment of insulin resistance (HOMA-IR).
Results: At all timepoints of the OGTT, circulating vaspin concentrations were similar in women with GDM and NGT during pregnancy (1.54±0.86 vs. 1.33±0.76, p>0.05) as well as three months after delivery (0.26±0.42 vs. 0.32±0.69, p>0.05). Post-partum, plasma vaspin levels decreased significantly in both groups (p<0.01, respectively), however, to similar extent (p>0.05). Only in women with GDM, circulating vaspin was significantly decreased 60 and 120 min after glucose ingestion during pregnancy (p<0.01). Plasma vaspin concentrations correlated signficantly with glutamic-oxaloacetic transaminase during pregnancy (r=-0.49, p=0.03) as well as serum estrogen levels (r=-0.51, p=0.03), sexual hormone-binding globuline (r=-0.46, p=0.05) and serum creatinine (r=0.53, p=0.02) three months after delivery. No association between circulating vaspin levels and parameters of insulin sensitivity including HOMA-IR, fasting glucose, insulin or C-peptide levels have been observed.
Conclusion: In contrast to previous studies, we found no association between parameters of insulin sensitivity and circulating vaspin concentrations in women with GDM. Interestingly, following glucose loading plasma vaspin concentrations decreased only in women with GDM. Additionally, pregnancy seems to result in an elevation of circulating vaspin.

1094

Plasma chemerin concentrations in relation to parameters of insulin sensitivity in women with gestational diabetes

A. Handisurya[1], Y. Winhofer[2], J. Todoric[3], A. Tura[4], K. Klein[5], D. Bancher-Todesca[5], G. Pacini[4], H. Esterbauer[3], A. Kautzky-Willer[2];
[1]Department of Internal Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna, Austria, [2]Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [3]Clinical Institute for Medical and Chemical Laboratory Diagnostic, Medical University of Vienna, Austria, [4]Metabolic Unit, National Research Council, Institute of Biomedical Engineering, Padova, Italy, [5]Department of Obstetrics and Gynecology, Division of Feto-Maternal Medicine, Medical University of Vienna, Austria.

Background and aims: Chemerin, a novel adipokine, is a chemoattractant protein with several functions in innate and adaptive immunity and implicated in the regulation of glucose homeostasis. Previously, chemerin was found to enhance insulin-stimulated glucose uptake in 3T3-L1 adipocytes, to induce insulin resistance in skeletal muscle and to exacerbate glucose intolerance in mice, when administered exogenously. In humans, circulating

chemerin levels are increased in insulin-resistant states, including obesity, polycystic ovaries syndrome or non-alcoholic fatty liver disease, and to decrease following bariatric surgery. Further, insulin and metformin were suggested to regulate circulating chemerin concentrations. The objective of the present study was to evaluate whether GDM is associated with changes in plasma chemerin concentrations.
Materials and methods: Plasma chemerin concentrations were measured in 20 pregnant women (10 GDM and 10 NGT) at 0, 30, 60 and 120 min of a 2h-75g-oral glucose tolerance test (OGTT) during gestational week 21-28 and three months after delivery by a commercially available ELISA kit (R&D Systems, Minneapolis, MO). Fasting insulin sensitivity was estimated by the homeostasis model assessment of insulin resistance (HOMA-IR).
Results: No differences in circulating chemerin levels at any timepoint of the OGTT were observed between GDM and NGT during pregnancy or after delivery (p>0.05). However, the decrease in plasma chemerin concentration between 0 min and 30, 60 or 120 min of the OGTT was more pronounced in women with GDM during pregnancy (p<0.05, respectively) but not postpartum. Fasting plasma chemerin levels correlated with HOMA-IR (r=0.54, p=0.01), fasting insulin (r=.0.53, p=0.02) and fasting C-peptide levels (r=0.69, p<0.001), HDL-cholesterol (r=-0.47, p=0.04), CRP (r=0.58, p=0.008) and usCRP (r=0.65, p=0.004) during pregnancy and with HOMA-IR (r=0.54, p=0.02), fasting insulin (r=0.56, p=0.02) three months after delivery. The decrease in plasma chemerin following delivery (p<0.05, respectively) tended to be higher in women with GDM (p=0.08).
Conclusion: Our study shows that plasma chemerin levels correlated with parameters of insulin sensitivity and inflammation also in women with GDM. However, no significant differences have been found in women with GDM as compared to pregnant, normal-glucose tolerant women. Thus, the potential role of chemerin in the pathogenesis of GDM remains to be determined.

Circulating endothelial progenitor cells are reduced in pregnant women with abnormalities of glucose tolerance

L. Pucci[1], D. Lucchesi[1], C. Lencioni[1], E. Storti[1], M.C. Iorio[2], R. Vanacore[2], V. Resi[1], R. Miccoli[1], G. Penno[1], G. Di Cianni[1], S. Del Prato[1];
[1]Endocrinology and Metabolism, [2]Blood Bank, University of Pisa and Azienda Universitaria Ospedaliera Pisana, Pisa, Italy.

Background and aims: Bone marrow-derived endothelial progenitor cells (EPCs) contribute to support vascular integrity. A role for EPCs has been claimed also in development and maintenance of the vasculature during pregnancy whose cardiovascular adaptation sustains the developing foetus. Gestational diabetes is associated with systemic endothelial dysfunction, but only a very few data about EPCs in pregnancies complicated by diabetes are available.
Materials and methods: We quantified circulating EPCs in pregnant women with abnormalities of glucose tolerance undergoing a three-hour, 100-g oral glucose tolerance test (OGTT). Insulin sensitivity and β-cell function indexes were derived from fasting steady-state and from the OGTT. EPCs (CD34+KDR+CD133+ cells) were quantified by three colours flow cytometry in 23 women with normal glucose tolerance (NGT), 18 women with gestational impaired glucose tolerance (GIGT) - defined as a single abnormal value on OGTT - and 24 subjects with gestational diabetes mellitus (GDM). Tests were performed at 27±3.2 weeks of gestation.
Results: Women with GDM, GIGT and NGT were comparable for age, family history of diabetes, pre-pregnancy body weight, BMI, incremental gestational body weight and blood pressure. GDM showed mean glycemic response higher than women with GIGT and NGT. AUCGluc (p<0.0001) and AUCIns (p=0.06) increased from NGT to GIGT to GDM. Insulin sensitivity indexes, ISIcomp and OGIS, reduced progressively in women with NGT to those with GIGT and GDM (ISIcomp: 4.92±2.05, 4.43±2.68, and 3.35±1.87, respectively, p<0.05; OGIS 387±53, 357±70, and 316±79 mg/min/m2, respectively, p<0.005). Finally, the ISSI index that estimates insulin secretion with respect to prevalent insulin sensitivity, was higher (p<0.0001) in women with NGT. The number of circulating CD34+ cells resulted similar in the three groups (NGT: 353.7±165.9; GIGT: 417.2±242.5; GDM: 423.3±220.0 cells/106 events), while circulating EPCs differed among women with GDM, GIGT and NGT (p=0.0172). Namely, EPCs were significantly higher in NGT (55.6±57.8) when compared to both GIGT (26.5±19.6; p=0.018), and GDM (26.5±20.4 cells/106 events; p=0.011), with no differences between GIGT and GDM. EPCs were inversely correlated with age (r=-0.26, p=0.04), as well as with 1-h (r=-0.30, p<0.02) and 2-h post-load plasma glucose (r=-0.36, p<0.005), and AUCgluc (r=-0.37, p<0.005), but not with insulin levels or AUCins. A weak positive correlation was also observed between EPCs and ISSI (r=0.25, p<0.05). Finally, no associations have been shown between EPCs and fasting (HOMA%S: r=-0.13, p=0.32) or dynamic indexes of insulin sensitivity (ISIcomp: r=0.01, p=0.95; OGIS: r=0.15, p=0.24). In a multiple linear regression model, only age (p=0.021) and AUCgluc (p=0.027) remained significantly associated with EPCs count.
Conclusion: Alterations of glucose tolerance during pregnancy, other than affecting insulin sensitivity and secretion, seems to act as the triggering factor for the EPC depletion.

1096

A high level of prorenin in early pregnancy is associated with development of preeclampsia in women with type 1 diabetes

L. Ringholm[1,2], U. Pedersen-Bjergaard[3], B. Thorsteinsson[3,4], F. Boomsma[5], P. Damm[4,2], E.R. Mathiesen[1,2];
[1]Endocrinology, University Hospital of Copenhagen Rigshospitalet, Copenhagen, Denmark, [2]Center for Pregnant Women with Diabetes, Copenhagen, Denmark, [3]Endocrinology Section, Department of Cardiology and Endocrinology, Hillerød Hospital, Denmark, [4]Faculty of Health Sciences, University of Copenhagen, Denmark, [5]Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Background and aims: Preeclampsia is characterised by abnormal placentation in early pregnancy, maternal systemic endothelial dysfunction and perturbation of the renin-angiotensin-system. Levels of semicarbazide-sensitive amine oxidase (SSAO) have been shown to be positively associated with angiotensin converting enzyme (ACE) activity and are elevated in patients with diabetes. SSAO is implicated in the pathophysiology of diabetic late complications and may be a marker of endothelial dysfunction and preeclampsia. We investigated whether SSAO and components of the renin-angiotensin system in early pregnancy are associated with development of preeclampsia in women with type 1 diabetes.
Materials and methods: Observational study of 107 consecutive pregnant women with type 1 diabetes for median 16 years (range 1-36) and HbA_{1c} 6.6% (4.9-10.5) in early pregnancy. At 8, 14, 21, 27 and 33 weeks blood samples were drawn for measurements of prorenin, renin, angiotensinogen, ACE and SSAO; HbA_{1c}, blood pressure and urinary albumin excretion (UAE) were recorded. Preeclampsia was defined as blood pressure >140/90 mmHg (two measurements) accompanied by UAE ≥300 mg/24h later than 20 weeks.
Results: Preeclampsia was recorded in nine women (8%) characterised by a longer duration of diabetes (median 20 years (range 10-32) vs. 16 (1-36), p=0.04) and higher levels of SSAO at 8 weeks (592 (372-914) mU/L vs. 522 (264-872), p=0.04, normal range 352±102 mU/l) compared with women without preeclampsia. At 8 weeks prorenin levels tended to be elevated in women with subsequent preeclampsia (136 (50-296) mU/L vs. 101 (21-316), p=0.06, normal range 88 to 390 mU/L), whereas levels of renin, angiotensinogen and ACE were comparable (p=0.90, 0.73 and 0.91, respectively). From 8 to 33 weeks prorenin levels decreased slightly and similarly in women with and without preeclampsia, but throughout pregnancy, prorenin levels remained 28% higher (p=0.0096) and SSAO levels 16% higher (p=0.04) in women developing preeclampsia whereas levels of renin, angiotensiongen and ACE were comparable between the two groups (p=0.49, 0.75 and 0.53, respectively). In univariate logistic regression analyses of continuous variables, development of preeclampsia was associated with prorenin levels at 8 weeks (odds ratio 4.4 [95% confidence interval 1.5-13.0], p=0.007), UAE (≥30 vs. <30 mg/24h) at 8 weeks (3.1 [1.3-7.7], p=0.01), SSAO levels at 8 weeks (1.8 [1.1-3.1], p=0.01) and duration of diabetes (1.1 [1.003-1.2], p=0.04). In multivariate logistic regression analysis, the only independent predictor of preeclampsia was prorenin levels at 8 weeks (4.4 [1.5-13.0], p=0.007), i.e. an increase of prorenin of 100 mU/L results in a 4.4 times higher risk of developing preeclampsia.
Conclusion: In women with type 1 diabetes, a high level of prorenin in early pregnancy was associated with development of preeclampsia. Whether these changes in the renin-angiotensin system mainly reflect maternal susceptibility present before pregnancy or represent changes secondary to abnormal placentation remain speculative.

1097

Relationship between perinatal outcomes and thyroid-peroxidase antibodies (TPO) in a cohort of pregnant women with gestational diabetes (GD)

S. Azriel[1], A. Garcia Burguillo[2], I. Camaño[2], D. Montañez[2];
[1]Endocrinology, Hospital Infanta Sofia, Madrid, [2]Hospital Doce de Octubre, Obstetrics, Spain.

Background and aims: The prevalence of TPO antibodies in pregnant women ranges between 6-10%, in line with what is found in the average population. Various non-organ specific auto-antibodies have been found associated with GD. The presence of TPO antibodies has been independently related to increasing rates of spontaneous abortion, preterm delivery, and it has recently been demonstrated that in the first trimester there is a risk factor of perinatal death. The aim of this study was to evaluate the effect of maternal autoimmunity on perinatal outcomes and on maternal morbidities.
Materials and methods: GD was diagnosed in a cohort of 1501 pregnant women without pregestational thyroid dysfunction, gestational age in the first visit >12 week, singleton pregnancy and availability of TPO antibodies titer
Results: 341 patients (22.72%) were TPO antibodies positive (>11.9 U/ml). There were no differences between the groups of pregnancies according to TPO antibodies status in mean maternal age [32.6 (SD: 4,2) vs 32.7 (7.5) years], BMI [24.9 (4.7) vs 24.9 (6.6) kg/m^2], frequency of nulliparities [163 (47,8) vs 553 (47,6)], percentage of insulinizations [61 (17,8) vs 72 (14,8) %] and average of A1c hemoglobin [4,24 (0,47) vs 4,26 (0,53) %]. There were no significant differences as regards the prevalence of the hypertension (pregestational + gestational) [18 (5,2) vs 56 (4,8) %], preeclampsia [4 (1,1) vs 16 (1,3) %] among the women with positive TPO antibodies and the group with negative TPO antibodies. We demonstrated a higher frequency of recurrent miscarriages (≥ 3 abortions) among pregnant GDM with TPO+ *vs* pregnant GDM with TPO- [12 (1.35) vs 14 (1.2), RR: 2,61: CI 95: 1.22-5.60)].There were no differences between the percentage of preterm deliveries (<34 weeks of pregnancy [7 (2,05) vs 12 (1,03) %] nor in <32 weeks [3 (0,87) vs 6 (0,51)]). Perinatal mortality was equiparable between both groups of women [1 (0,29) vs 2 (0,17)]. There were no differences between the mean weight of neonates, no differences in the prevalence of big for gestational age [14 (4,1) vs 53 (4,5) %] nor in the neonates with weight <2500 g [13 (3,8) vs 36 (3,1) %].
Conclusion: Considering the high prevalence of positive TPOantibodies in women with GD and the increasing risk of developing postpartum dysfunction in this group, a screening of thyroid function during pregnancy and a postpartum follow-up are recommended for these women. This study confirms the correlation between positive TPO during the pregnancy and higher frequency of recurrent miscarriage. In our cohort, thyroid autoimmunity is not related with an adverse effect on perinatal outcome in the babies born to patients with GD.

1098

The influence of pregnancy and gestational diabetes on serum levels of osteocalcin, osteoprotegerin and RANKL

B. Telejko[1], K. Kalejta[1], M. Kuzmicki[2], A. Nikolajuk[1], J. Szamatowicz[2], A. Kretowski[1], M. Górska[1];
[1]Department of Endocrinology, Diabetology and Internal Medicine, [2]Department of Gynecology, Medical University of Balystok, Bialystok, Poland.

Background and aims: Osteoprotegerin (OPG), a soluble tumor necrosis factor-like protein secreted by osteoblasts, exerts an inhibitory effect on osteoclastic bone resorption by binding and neutralizing the receptor activator of nuclear factor-κB ligand (RANKL). Besides, OPG has other biological functions, including anti-inflammatory and anti-apoptotic effects. Recent studies suggest also that osteocalcin, another osteoblast - derived protein acting locally on bone formation, increases beta-cell proliferation and insulin secretion and improves insulin sensitivity. Conflicting results concerning serum osteocalcin and osteoprotegerin concentrations have been obtained in patients with obesity, type 2 diabetes,as well as gestational diabetes (GDM). The aim of the present study was to evaluate possible changes in serum osteocalcin, OPG and RANKL levels in pregnant women with normal glucose tolerance (NGT) and GDM.
Materials and methods: Serum osteocalcin, OPG and RANKL levels were measured, using enzyme-linked immunosorbent assays, in 47 patients with GDM and 35 healthy pregnant women in the 3rd trimester of pregnancy and 12 weeks postpartum.
Results: There were no significant differences in the concentrations of osteocalcin, OPG and RANKL between the women with GDM and NGT both before (7.8 [5.6-10.5] ng/ml vs 9.5 [5.1-12.7] ng/ml, 6.3 [4.9-7.2] pmol/l vs 5.4 [3.8-7.2] pmol/l and 0.22 [0.14-0.59] pmol/l vs 0.31 [0.12-0.46] pmol/l, respectively) and after delivery (22.1 [16.5-29.6] ng/ml vs 23.1 [17.4-29.7] ng/ml, 4.2 [3.7-5.2] pmol/l vs 3.9 [3.4-4.5] pmol/l and 0.26 [0.13-0.48] pmol/l vs 0.31 [0.10-0.62 pmol/l, respectively). Twelve weeks postpartum serum osteocalcin concentrations increased (p<0.0001), whereas OPG levels decreased significantly (p<0.0001) in both groups of patients in comparison with the pregnant state. In the whole group studied there was a significant correlation between osteocalcin levels and gestational age (R=0.30, p=0.02). In healthy pregnant women osteocalcin levels correlated with gestational age (R=0.45, p=0.04) and BMI values (R=0.83, p=0.04), while OPG concentrations were related to glucose levels 60 and 120 min after glucose load (R=0.57, p=0.005 and R=0.50, p=0.01, respectively). In the same group there was also a negative correlation between RANKL concentrations and gestational age (R=-0.42, p=0.04). No associations of the parameters studied with insulin and HOMA-IR were noted.
Conclusion: It could be hypothesized that lower osteocalcin levels may be related to decreased insulin sensitivity and increased fat mass in pregnant women. On the other hand, increased OPG concentrations, possibly due to elevated estrogen levels during pregnancy, may play protective roles including an inhibition of excessive bone resorption and anti-inflammatory actions. No effect of GDM on serum osteocalcin and OPG/RANKL system was found in the present study.

Vitamin D deficiency and isolated fasting hyperglycaemia in pregnancy

E. Anastasiou, A. Athanasiadou, V. Vasileiou, A. Giakoumi, G. Papageorgiou, E. Zapanti, M. Alevizaki;
Alexandra Hospital, Athens, Greece.

Background and aims: The relation between vitamin D deficiency and Gestational Diabetes Mellitus (GDM) has been rarely addressed in the literature with conflicting results. The aim is to determine the association between maternal serum 25(OH)D and glucose metabolism in Caucasian pregnant women.
Materials and methods: In a prospective study 157 pregnant women aged 31.2±5.8 years underwent a 100g OGTT in the third trimester of pregnancy, during which serum 25(OH)D, PTH, Ca, and P concentrations were also measured. For GDM diagnosis the ADA 2000 criteria were used. For 25(OH)D deficiency a cut-off point of 20ng/ml was chosen. Age, height, prepregnancy weight, BMI and blood pressure (BP) were recorded. Indices of insulin secretion and sensitivity were calculated. 25(OH)D was converted to its natural logarithm(Ln).
Results: 25(OH)D deficiency was found in 88 out of 157 pregnant women(56%). There was no difference in mean serum 25(OH)D between Normal (n=95, 20.2±7.0ng/ml), Isolated Hyperglycaemia (n=30, 22.1±7.7) and GDM (n=32, 19.4±8.3) women. Ln-25(OH)D was negatively correlated with fasting plasma glucose (r=-0.174, 95% CI 0.020-0.326, p=0.029). The relationship remained significant after adjustment for BMI, age, gestational age and seasonal variation. The percentage of isolated fasting hyperglycaemia (Glu0 ≥ 95mg/dl) was significantly increased in the subgroup of pregnant women with vitamin D deficiency (<20ng/ml) compared to the counterparts with 25(OH)D>20ng/ml (27.3% vs7.2% respectively, p<0.01). The odds ratio of isolated fasting hyperglycaemia in women with 25(OH)D<20ng/ml was 4.8 (95% CI 1.7-13.3). Also, a weak but significant correlation was found between Ln-25(OH)D and indices of insulin resistance (QUICKI: r=0.191, p<0.05, HOMA-IR: r= -0.192, p<0.05). There was no correlation between Ln-25(OH)D and indices of insulin secretion. Further, we confirmed the expected negative correlation of Ln-25(OH)D with PTH (r=-0.446, p<0.001), and also with systolic (r=-0.203, p=0.011) and diastolic BP(r=-0.238, p=0.003).
Conclusion: We found an independent negative correlation of 25(OH)D with fasting glucose in pregnant women. Furthermore 25(OH)D deficiency was significantly associated with increased risk for isolated fasting hyperglycaemia. Finally 25(OH)D deficiency is common in Greek pregnant women.

Markers oxidative stress and antioxidant status in women with late-onset gestational diabetes mellitus

C. López-Tinoco[1], A. García-Valero[1], J. Bartha[2], M. Aguilar-Diosdado[1];
[1]Endocrinology, [2]Obstetric, Hospital Puerta del Mar, Cádiz, Spain.

Background and aims: The relationship between late-onset gestational diabetes mellitus [GDM] and oxidative stress is not well known and the importance of the oxidant/antioxidant equilibrium in the clinical evolution and complications of late-onset GDM require elucidation. The aim of the present study was to evaluate the relationships between maternal serum levels of markers of oxidative stress in women with late-onset GDM which potentially may have considerable clinical implications in the pathogenesis and/or the evolution of GDM.
Material and methods: We performed a nested case-control study within a sample of a total of 126 pregnant women (63 with GDM, 63 controls), between the 24th and 29th week of gestation. Both groups were analyzed for demographic data, perinatal and obstetrics results and the levels of the markers oxidative stress and antioxidants status, that were measured in serum or plasma using a commercial kit (Cayman Chemical, Ann Arbor, MI, USA).
Results: In the univariate analysis, control *versus* patient results were: maternal age 30.52±4.05 vs. 31.43±4.4 years (p=0,1); pre-gestational body mass index [BMI] 23.31±4.2 vs. 27.13±4.6 kg/m^2 (p=0.001); weeks at delivery 39.2±3.05 vs. 38.9±1.8 (p=0.09); Caesarean delivery 12.5 vs. 43% (p=0.004); macrosomia 4 vs. 9.4% (p=0.6); lipoperoxides [LPO] 2.06±1.00 vs. 3.14±1.55 µmol/mg (p=0.001); catalase 3.23±1.41 vs. 2.52±1.3 nmol/min/ml (p=0.03); superoxide dismutase [SOD] 0.11±0.04 vs. 0.08±0.01 U/ml (p=0.0003); glutathione peroxidase [GPX] 0.03±0.006 vs. 0.025±0.006 nmol/min/ml (p=0.01); glutathione reductase [GSH] 0.004±0.002 vs. 0.004±0.004 nmol/min/ml (p=0.9); glutathione transferase [GST] 0.0025±0.0012 vs. 0.0027±0.00017 nmol/min/ml (p=0.7). Multivariate analysis that was performed using non-conditional logistic regression showed catalase having a protective effect against (OR=0.39, p=0.006) and LPO carried a significant risk for GDM (OR=2.44, p=0.034).
Conclusion: These data suggest an increase in oxidative stress and a decrease in antioxidative defence in women with late-onset GDM and, as such, may have considerable clinical implications in the pathogenesis and/or the course of the pregnancy in these patients.

1101

Oxidative stress may stay elevated after gestational diabetic and even healthy pregnancies

E.M. Horvath[1], R. Benko[1], R. Magenheim[2], G. Tamas[2], Z. Lacza[1], T. Pek[1], C. Szabo[3];
[1]Institute of Human Physiology and Clinical Experimental Research, Semmelweis University, Budapest, Hungary, [2]1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary, [3]Department of Anesthesiology, The University of Texas Medical Branch, Galveston, USA.

Background and aims: The number of pathological and moreover healthy pregnancies increases the risk of cardiovascular morbidity. Parous women with no complicated births have a 1.95-fold higher cardiovascular disease prevalence compared to nulliparas. Among women with one or more pregnancy complications, cardiovascular disease prevalence is 2.67 times higher. It was shown that increased oxidative stress can be observed during the course of normal pregnancy. Gestational diabetes mellitus (GDM) is associated with a pronounced degree of oxidative stress in placental and umbilical cord tissues and also in the plasma of the mother and the newborn. It is also known that elevated levels of oxygen and nitrogen derived reactive species are major contributors in the development of cardiovascular morbidities. Our aim was to examine the level of possibly persisting oxidative stress and its correlation to other known cardiovascular risk factors after pregnancy.
Materials and methods: Serum total peroxide level was measured in healthy volunteers three years following healthy (n=20), moderate GDM (carbohydrate-restricted diet, n=30) and severe GDM (insulin treatment, n=12) pregnancies. Controls were age and BMI matched males (n=10) and nulliparous women (n=14). In order to characterize their carbohydrate metabolism fasting glucose, HbA1c levels were measured and oral glucose tolerance test (oGTT, 75g) was performed. Serum glucose and insulin levels were determined in every 30 minutes, area under the curve was calculated. The following clinical parameters were also gauged: inflammatory markers, lipid profile, liver and kidney function, thyroid and sex hormones. Serum total peroxide level was measured in fasting conditions and 2hours following oGTT.
Results: The oGTT did not change the peroxide level in any study group. In fasting conditions the peroxide level of nulliparous women and men was similar. Previous healthy pregnancy significantly elevated (586.2±66.8 vs. 332.3±34.5umol/l, p<0.05) the peroxide level and previous moderate GDM did not increased it further on (657.2±46 umol/l). However severe GDM resulted in additional significant increase (951±147.7 umol/l p<0.05, vs. nulliparous, moderate GDM). Factors that may influence peroxide level were analyzed in multivariate regression model, in order to select significant variables stepwise method was used. According to the model peroxide level is significantly influenced by CRP (33.9umol/l, p<0.05) SHBG (2.7umol/l, p<0.05), total serum protein (22.8µmol/l, p<0.05) and the number of pregnancies (b=78.6 umol/l, p<0.05) (r2=0.46). The number of pregnancies significantly correlates with CRP (Pearson correlation: 0.32, p<0.05), which shows that the effect of previous pregnancy on peroxide level is partially due to the increase in CRP level.
Conclusion: According to our results the elevated oxidative stress that can be measured during pregnancy can be still observed three years after delivery. The level of oxidative stress is only altered by previous severe GDM, but not moderate GDM. Immunological processes may play important role in this phenomenon. The elevated level of oxidative stress may contribute to the increased cardiovascular morbidity of child-bearing women.

1102

Metabolic variables (fructosamine, HbA_{1c}) as predictors and pathophysiologic markers of gestational diabetes mellitus and diabetic fetopathy

B. Biesenbach;
Department of Internal Medicine II, Landes- Frauen- und Kinderklinik Linz, Austria.

Background and aims: The current therapeutic strategies to reduce macrosomia rates in GDM have focused on normalization of maternal glucose levels throughout pregnancy. This study compares HbA1c, fructosamine, a fructosamine/total protein ratio and an index consisting of fructosamine/ total protein x 1-h-postprandial glucose/100 in regard to their possibility as predictors and pathophyiological markers of GDM and infant´s macrosomia.
Materials and methods: A total of 715 pregnant women underwent an oral glucose tolerance test and were grouped in four categories according to their glucose tolerance and infant´s birthweight. 85.9% (307) women with NGT had normal weight children, while 13.9% (50) presented with macrosomia. For women with GDM, 89.1% (319) gave birth to a child with normal weight, while 39 (10.9%) delivered macrosomic infants. In all pregnant women 89 women (~12%) presented with fetal macrosomia. Subsequent HbA1c, fructosamine, ratio and index were compared in regard to their accurancy for the diagnosis of GDM and macrosomia by ROC curves.
Results: We found a poor correlation of fructosamine with oGTT data, although the ratio was developed as a more sensitive form than single serum fructosamine concentration. According to correlations between HbA1c and oGTT values, we can conclude that HbA1c measurements have low sensitivity as predictive markers for diagnosis of GDM as well as for macrosomia, both in NGT and GDM subjects.Due to strict glycemic control (blood glucose fasting < 91 mg/dL, 1 hour postprandial < 131 mg/dL) there was no difference in the rate of macrosomia. In all women birthweight was associated with BMI, fasting plasma glucose, calculated ratio, HbA1C, weight and gestational age (all data preconceptional). For women with NGT only obesity seems to have an impact on infants´ birthweight, while for women with GDM additional metabolic parameters apart from obesity affect fetal growth. Ratio was the only variable able to differentiate within the GDM subgroups and was the best predictor for birthweight of infants. On the other hand the index achieved a satisfying sensitivity in regard of diagnosis of GDM. For women with macrosomic infants again the index was superior in detecting GDM.
Conclusion: In conclusion, women with GDM feature higher levels of HbA1c and fructosamine as well as higher index values. Due to overlap of NGT and GDM groups none of these parameters can offer an alternative to standard oGTT screening procedures but could be used as additional parameters for confirmation of impaired glucose tolerance and prediction of worse outcome. It remains the central target to modify the traditional GDM screening process in order to provide a test that should be more reliably detecting those women at risk of developing GDM during pregnancy and/or delivering a macrosomic infant despite negative testing for GDM.

1103

The effect of weight gain on gestational diabetes mellitus

Y. Baci[1], I. Üstüner[2], L. Keskin[2], R. Ersoy[3], A. Sivaslıoğlu[2], A.F. Avşar[2];
[1]Department of Family Medicine, [2]Department of Obstetrics and Gynecology, [3]Department of Endocrinology and Metabolism, Ankara Atatürk Education and Research Hospital, Turkey.

Background and aims: To evaluate the association between gestational diabetes mellitus (GDM) and weight gain during pregnancy.
Materials and methods: A prospective cohort study of 614 consecutive gravid patients, screened for GDM using 50-gram glucose challenge test (GCT) between June - December 2009. The pregnant women were divided into 4 groups according to their pre-pregnancy body mass index (BMI). Group I, II, III and IV constituted when the BMI <18.5 kg/m^2 (n=16), 18.5-24.9 kg/m^2 (n=455), 25-29.9 kg/m^2 (n=122) and >30 kg/m^2 (n=21), respectively. All the pregnant women were also evaluated in terms of their weight gain during pregnancy and these cases were recruited in 3 groups as low, ideal and high weight gained groups.
Results: Overall, a positive GCT result was identified in 109/614 (17.8%) women. GDM was further diagnosed in 12/614 (1.95%) of subjects. While the prevalence of GDM in patients with a normal pre-pregnancy weight was 1.31%, in over-weight and obese patients it was 3.28% and 9.52% respectively. The frequency of the GDM significantly increases in obese patients at the pre-pregnancy period compared to the ones with normal BMI. The cases of group II and group III showed statistically significant positive results of 50 g GCT when they had excess weight gain compared to the ones whose weight gain stand in a normal range.
Conclusion: If the women with normal BMI gain more than the recommended weight range during their pregnancy, they should be regarded as having risk for GDM.

1104

The effect of lactation on glucose and lipid metabolism in women with prior gestational diabetes

A. Colatrella, C. Festa, G. Merola, M. Bongiovanni, L. Mattei, A. Napoli;
Clinical and molecular medicine, 2nd faculty of, Rome, Italy.

Background and aims: Lactation confers health benefits to women with a history of gestational diabetes (GDM). Breastfeeding improves glucose tolerance in the early postpartum period, but it is unclear whether future risk of metabolic alterations, like type 2 diabetes, is reduced. The aim of this study was to investigate the effect of lactation, three years after pregnancy, on glucose and lipid metabolism in women with prior gestational diabetes.
Materials and methods: A population of women with prior gestational diabetes, according to Carpenter and Coustan Criteria, was evaluated with comparison of results for lactating versus nonlactating women. A total of 81 women participated (62 breastfeeding [BF] and 19 nonbreastfeeding [<4 weeks , nonBF]). Each woman completed a 75-g oral glucose tolerance test (OGTT) to analyze glucose tolerance, insulin sensitivity / resistance and b-cell function. Fasting serum was used to investigate lipid profile (total cholesterol, high-density lipoprotein [HDL] cholesterol, low-density lipoprotein [LDL] cholesterol, and triglycerides), apolipoprotein B, apolipoprotein A1, homocysteine, fibrinogen, hs- CRP, uric acid, microalbuminuria. STATISTICS: paired and Un-paired t-test, Mann-Whitney and χ^2 tests were used, as appropriate.
Results: The mean (+/- standard deviation) maternal age (37.1 +/- 4.6 versus 37.4 +/- 4.9 years), body mass index (26.3+/- 5.6 versus 26.4 +/- 5.3 kg/m2), and parity (1.9+/- 0.8 versus 1.7 + 0.8) , were not different between the lactating and nonlactating women. No effect was visible on glucose tolerance, HOMA-IR and other b-cell function indexes as well as hs- CRP (not significantly lower in non BF), uric acid, total cholesterol, HDL and LDL cholesterol. Levels for significance were only found for: HOMA-IS (BF1.0 +/- 0.7 vs non BF 0.6 +/- 0.4, p = 0.04), Triglycerides (BF 83.8 +/- 46.7 vs non BF 123.2 +/- 94.0 mg/dl, p = 0.02).
Conclusion: Breastfeeding had no effects on glucose tolerance status three years after the delivery of women with prior GDM.

1105

Association of fatty liver index (FLI) with parameters of insulin sensitivity in women with prior gestational diabetes

C.S. Göbl[1], L. Bozkurt[1], A. Tura[2], A. Luger[1], G. Pacini[2], A. Gastaldelli[3], A. Kautzky-Willer[1];
[1]Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [2]Metabolic Unit, Institute of Biomedical Engineering, Padova, Italy, [3]Department of Biochemistry clinical Physiology, Consiglio Nazionale delle Richerche (CNR), Pisa, Italy.

Background and aims: Most of the important risk determinants of the metabolic syndrome, including obesity, insulin resistance, glucose intolerance, dyslipidemia and hypertension are present in women with prior gestational diabetes (pGDM) and indicate their high risk for developing type 2 diabetes and cardiovascular disease (CVD) in later life. Fatty liver (FL) is associated with insulin resistance, in particular in the liver, and with CVD. The aim of the study was to evaluate the relationship between pGDM, presence of FL and insulin resistance.
Materials and methods: A cross-sectional analysis was performed in 62 pGDM women and 28 women with normal glucose tolerance during pregnancy (NGT) until 3 months after delivery. According to ivGTT insulin sensitivity index (SI), pGDM were divided into insulin resistant (IR; SI<2.8 10^{-4} $min^{-1}/(\mu U/ml)$) or insulin sensitive (IS). The fatty liver index (FLI>60 =likelihood >78% presence of FL; FLI<20=likelihood >91% absence of FL) was calculated for each group and was correlated with metabolic parameters.

Results: Women with pGDM presented significantly higher FLI levels than women with NGT (30.0±3.6[SEM] vs. 20.6±5.6[SEM], p=0,008). In particular IR women showed higher FLI-values compared to IS (45.9±6.5 vs. 19.2±3.3, p=0.002). 16.1% of pGDM vs. 10.7% of NGT had FLI-values >60. In the whole sample FLI was negatively correlated with OGIS (r_S=-0.58, p<0.001) and HDL-cholesterol (r_S =-0.45, p<0.001). In addition, FLI was positively correlated with systolic and diastolic blood pressure, CRP, usCRP and liver enzymes. Further, we found a negative association with Adiponectin as well as a positive association with Leptin.
Conclusion: Results suggest that women with pGDM are at higher risk for fatty liver disease. In particular insulin resistance is associated with significantly high FLI-values indicating that fatty liver could be another early marker for progression of the disease.

Parameters included in FLI

	PGDM	NGT	p-value
BMI (kg/m^2)	27.4±0.7	25.4±1.2	0.113
Triglycerides (mg/dl)	111.7±7.9	90.1±8.6	0.102
γGT (U/l)	8.6±0.6	11.5±2.0	0.083
Waist (cm)	92.4±1.8	80.8±3.1	0.001

Changes in humoral autoimmunity in pregnant women with abnormal glucose tolerance

K.N. Todorova - Ananieva[1], K.V. Petkova[2], E.I. Konova[3], M.G. Stamenova[2];
[1]High-risk Pregnancy Department, Specialized Hospital of Obstetrics and Gynaecology, Sofia, [2]Institute of Biology and Immunology of Reproduction, Sofia, [3]Clinical Institute of Immunology of Reproduction, Pleven, Bulgaria.

Background and aims: Autoantibodies (AAs) against pancreatic β-cell antigens cause autoimmune destruction, followed by β-cell dysfunction. The presence of autoimmune markers in pregnant women is the potential for increased risk for the future development of type 1 diabetes mellitus (T1DM). The aim of the study is to evaluate the changes in hummoral autoimmunity in high risk for T1DM pregnant women with normal and abnormal glucose tolerance.
Materials and methods: A one year prospective study among 96 pregnant women was performed in the period March 2008 - March 2009. A 75 grams Oral Glucose Tolerance Test (OGTT) was performed between 24 - 26 gestational weeks. The levels of blood glucose (BG) and immunoreactive insulin (IRI) has been measured at 0 min., 60 min. and 120 min. According to the results of OGTT the patients were divided into two groups: pregnant with normal carbohydrate tolerance (g_1= 53) and pregnant with impaired carbohydrate tolerance (g_2 = 43). The presence of antibodies against insulin (AIA), glutamic acid decarboxylase (GAD65) and one of the heat stress shock protein (AHspA) was examined in sera using indirect ELISA (AIA and AHspA) and EIA (GAD65) methods. All statistical analyses were performed with statistic panel - SPSS for Windows version 11.0.1. The difference between groups was compared by two tailed Student's *t*-test.
Results: Seven sera from the g_1 (13.2%) and five sera from the g_2 (11.6%) were positive for AIA (P>0.05). GAD65 autoantibodies were found in one serum from the g_1 (1.8%) and seven sera from the g_2 (16.2%); (P<0.001). Sequent analysis for AHspA has found two positive sera in g_1 (3.8%) and four positive sera in g_2 (9.3%); (P>0.05). There were statistically significant difference in total percentage of presence of autoantibodies between g_1 and g_2 groups (18.8% vs. 37.2%; P<0.03). We have fond positive correlation between BG levels during OGTT and presence of AHspA in g_2 (P<0.04). There was positive correlation between basal IRI levels at 0 min. and presence of AIA (P<0.02) in group$_2$. Four pregnant women positive for IAI of g_1 (51.7%) and three pregnant positive for IAI of g_2 (60.0%) have first and second degree relatives with T2DM. Five pregnant of GAD65 positive of g_2 (71.4%) have first and second degree relatives with T1DM.
Conclusion: These data support that autoimmune markers for pancreatic β-cell destruction are elevated in pregnant women with abnormal OGTT. In the absence of effective methods for prevention of T1DM measurement of immunologic markers in pregnant with high hereditary risk should be important tool for studying the progress of β-cell dysfunction.

1107

Pancreatic islets in human gestational diabetes

M. Tancredi[1], L. Marselli[1], L. Volpe[1], M. Masini[1], C. Lencioni[1], M. Bugliani[1], F. Dotta[2], P. Masiello[1], G. Di Cianni[1], P. Marchetti[1];
[1]University of Pisa, Pisa, Italy, [2]University of Siena, Italy.

Background and aims: Autoptic studies have shown an increased amount of islets and beta-cells in human pregnancy. However, no information is currently available on the properties of islet cells in human gestational diabetes. Here we describe several morphological, ultrastructural and functional properties of islets from a 33 yrs old woman with gestational diabetes (GD), who died for cerebral hemorrhage (rupture of a congenital aneurysm) at the 27th week of gestation. GD had been diagnosed at the 22th week, and therapy at time of death was with 32 IU insulin per day. At last control, fasting plasma glucose was 104 mg/dl and HbA1c was 6.1%.
Materials and methods: Immunohistochemical stainings and electron microscopy (EM) analyses were performed on pancreatic samples before islet isolation. Islet preparation was accomplished by collagenase digestion and gradient purification. Insulin secretion from the isolated islets was studied in response to glucose (3.3 and 16.7 mM), arginine (20 mM) and glibenclamide (100 μM).
Results: Islets area (diameter > 50 μm) was reduced in GD (0.55%) compared to non-diabetic controls (Ctrl) (1.32 and 1.47%), whilst islet insulin-positive area was higher in GD (66.0%) compared to Ctrl (51.9 and 47.2%). Apoptosis (cleaved caspase 3 immunohistochemistry and EM) was not different between the three cases, and Ki67 immunohistochemistry did not show replicating cells in the islets studied. The percentage of ducts with insulin-positive cells in the wall or within five nuclei far from it was not different between GD (27%) and Ctrl (45 and 23%); however, clusters (<10 cells) of insulin-positive cells scattered in the acinar tissue were more frequent in GD (1.35 per mm^2) compared to Ctrl (0.18 and 0.26 per mm^2). Ex-vivo insulin secretion was similar in GD and control islets.
Conclusion: In this case of human GD, a reduced amount of islets was observed; since apoptotic phenomena were similar in GD and control beta-cells, it is possible that not sufficient regeneration played a major role.

Hepatic and nonhepatic glucose uptake in a diet-induced model of gestational diabetes

M.C. Moore[1], K.C. Coate[1], M.S. Smith[1], M. Shiota[1], P.E. Williams[2];
[1]Molecular Physiology & Biophysics, [2]Surgery, Vanderbilt University, Nashville, USA.

Background and aims: Glucose delivery via the hepatic portal vein (or the "portal signal") enhances net hepatic glucose uptake (NHGU) but reciprocally inhibits nonhepatic and skeletal muscle glucose uptake. Thus the portal signal directs the partitioning of a glucose load among the tissues but does not increase whole body glucose uptake. Activation of glucokinase (GK) might explain the liver's response. We have shown that feeding a high-fat and -sugar diet (HFD; energy: 60% fat, 12% fructose or sucrose) to pregnant (P) dogs during gestational wks 5-8 (total gest=9 wk) alters the response to an OGTT, resulting in a canine model of gestational diabetes (GDM). It also worsens P-induced whole body and muscle insulin resistance and impairs suppression of hepatic glucose output during a hyperinsulinemic euglycemic clamp. We hypothesized that glucose disposal under hyperinsulinemic, hyperglycemic conditions in the presence of the portal signal would be impaired in HFD-fed P dogs.
Materials and methods: P dogs with chronic vascular catheterization to allow assessment of hepatic and hindlimb balance received a meat/chow diet (C; 26% fat, 42% CHO [2% sugar]) or the HFD during gest wks 5-8; *n*=7/group. In overnight-fasted conscious dogs during the 8th gest wk, somatostatin was infused to disable the endocrine pancreas, and glucagon (basal), insulin (4×basal), and glucose (4 mg·kg^{-1}·min^{-1}) were infused via the portal vein for 4h. Glucose was infused i.v. as needed to clamp the hepatic glucose load at 2×basal.
Results: Clamp period arterial (157±1 and 158±1 mg/dl) and portal (172±2 mg/dl in both) blood glucose, and arterial plasma insulin (25±2 and 28±3 μU/ml) and glucagon (48±5 and 37±2 ng/l) were not different in C and HFD, respectively. Subsequent data are for the last h of the clamp unless otherwise stated, and data are for C and HFD groups, respectively. The total glucose infusion rate was not different between groups (9.6±0.6 and 9.4±1.0 mg·kg

body wt^{-1}·min^{-1}). NHGU was reduced in HFD (15.0±1.5 vs 5.8±3.0 mg·100g liver^{-1}·min^{-1},*P*<0.05), and net hepatic lactate uptake was enhanced (13.3±10.0 vs 42.3±7.6 µmol·100g liver^{-1}·min^{-1}, *P*<0.05). Net hepatic carbon retention (17.9±1.4 and 9.7±2.6 mg glucose equivalents·100g liver^{-1}·min^{-1}, *P*<0.05) was reduced and terminal hepatic glycogen concentrations tended to be reduced (3.7±0.8 vs 2.4±0.4 g/100g liver; *P*=0.17) in HFD. Hepatic GK activity did not differ between C and HFD. Hindlimb (an index of skeletal muscle) glucose uptake was higher in HFD (9.8±1.1 and 19.8±1.9 mg/min, *P*<0.05), and nonhepatic glucose uptake tended to be higher in HFD (5.9±0.7 and 8.0±1.2 mg·kg body wt^{-1}·min^{-1}, *P*=0.06).
Conclusion: NHGU in the presence of hyperinsulinemia, hyperglycemia and the portal signal was reduced in HFD-fed dogs, but not in association with impaired catalytic activity of GK. Despite the presence of insulin resistance in the HFD dogs, the reciprocal nature of liver and skeletal muscle glucose disposal was maintained such that there was no reduction in whole body glucose disposal. In P women with impaired glucose tolerance or GDM, blunted NHGU could contribute to postprandial hyperglycemia, increasing the peripheral glucose load.

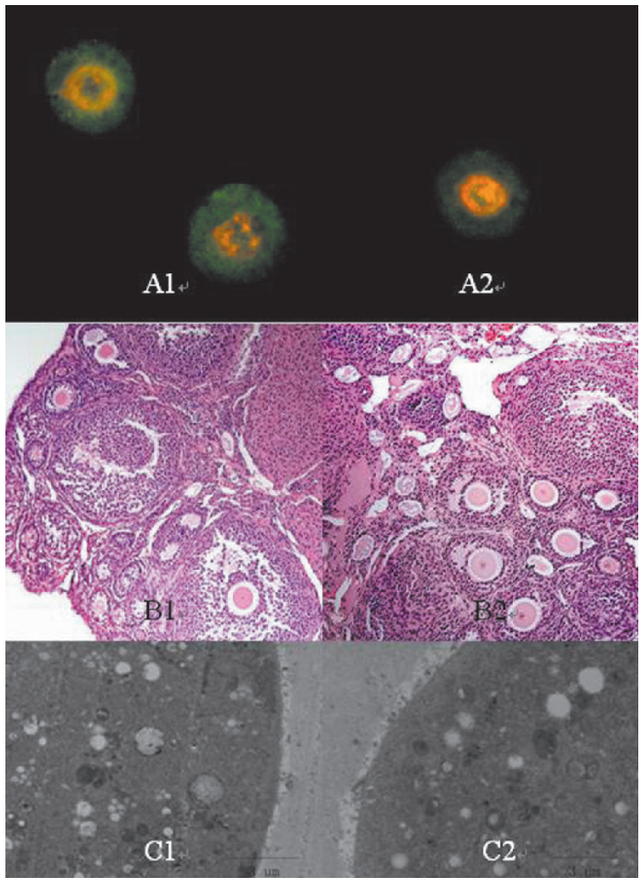
Maternal diabetes increases apoptosis in mice oocytes but not in 2-cell embryos
S. Lin, K. Lin, W. Li;
The First Affiliated Hospital of Shantou University Medical College, China.

Background and aims: It has been reported that diabetes-induced inappropriate apoptosis in the developing embryos and oocytes may be one of the mechanisms leading to congenital malformation or miscarriage. The objective of this study was to investigate the occurrence of apoptosis at an early stage of development, the oocytes and 2-cell embryos in streptozotocin (STZ)-induced diabetic mouse.
Materials and methods: Bax and Caspase-3 protein and mRNA were detected respectively by Immunofluorescent and quantitative reverse transcription-polymerase chain reaction in oocytes and 2-cell embryos from diabetic vs nondiabetic mice. Apoptosis was detected by Annexin-V staining. Furthermore, HE-stained ovarian sections were made to see the effect of hyperglycemia on the oocytes maturation and development, electron microscopy was used to see the effect of hyperglycemia on the ultrastructure of 2-cell embryos.
Results: The increased number of Annexin-V-positive cells occurred in diabetic oocytes compared to nondiabetic oocytes (P<0.05). In quantitative RT-PCR and immunofluorescent, Bax and caspase-3 expression were significantly increased in diabetic oocytes than in nondiabetic oocytes (P<0.05). HE-stained ovarian sections demonstrated that hyperglycemia resulted in delayed follicular growth as detailed by reduced number of growing follicles (P<0.05) and a reduction in follicle size (P<0.01). In contrast, no any Annexin-V-positive cells in 2-cell embryos were found in diabetic and nondiabetic mice. Although Bax expression was elevated in diabetic 2-cell embryos (P<0.05), caspase-3 expression in 2-cell embryos was no significant difference between diabetic and nondiabetic mice (P>0.05). Electron-Microscopy study revealed that more swollen mitochondrias were found in diabetic 2-cell embryos.
Conclusion: Maternal diabetes might increase oocyte apoptosis by a Bax-caspase-3 pathway to play a role in embryonic malformations by delayed oocyte development. Development of 2-cell embryos might be adversely affected by maternal diabetes, but not through Bax-regulated caspase-3 apoptotic pathway.



Typical images were from diabetic (left) and nondiabetic (right) mice. Immunofluorescent showed Bax expression was higher in diabetic oocytes (A1) than nondiabetic oocytes (A2). HE-stained ovarian sections demonstrated mature follicles were less in diabetic ovary (B1) than nondiabetic ovary (B2). Electron microscopy revealed the proportion of swollen mitochondria was significantly higher in diabetic (C1) than nondiabetic 2-cell embryos (C2).

Placental antioxidant capacity in gestational diabetes
P.G. Halvatsiotis[1], M. Vythoulka[1], K. Patsouras[2], M. Tsilika[1], G. Salamalekis[2], E. Salamalekis[2], T. Economopoulos[1];
[1]2nd Department of Internal Medicine - Propaedeutic, [2]3rd Department of Obstretics and Gynecology, Athens University Medical School, Greece.

Increasing evidence in experimental and clinical studies suggests that there is a close link between hyperglycemia, oxidative stress and diabetic complications. Gestational diabetes mellitus (GD) is a pathological state of carbohydrate intolerance first recognized during pregnancy. The incidence of major congenital malformations is much higher in pregnancies complicated by diabetes and it has been suggested that oxygen free radicals are involved in the fetal dysmorphogenesis associated with diabetic pregnancies. Decreasing activities of antioxidant enzyme capacity could be part of the pathogenesis and thus the purpose of our study was to examine whether the level of the antioxidant biomarker superoxide dismutase (SOD) activity in placental tissue is altered in GDM. We studied 6 women with GD (GDM) (29,2±2,2 y.o.) and 7 age matched (31,6±1,7y.o.) (p=0,392) women with normal glucose tolerance (NGT) who served as controls. We measured a biomarker activity of antioxidant defense, namely superoxide dismutase (SOD) (colorimetric based assay) in placental tissue samples, taken while the surgery for caesarean section. Statistical analysis performed with unpaired T-test. All pregnancies were fully termed, uncomplicated with normal newborns with no difference in birth weight (GDM: 3209,17±181,3 vs NGT: 2956,43±65,5 g) (p=0,236). GDM group demonstrated significantly higher plasma insulin levels vs NGT (12,87±1,5 vs 6,70±0,8 µIU/ml) (p=0,008), while at euglycemic levels 82,83±7,5 vs 67,75±5,2 mg/dl (p=0,18) indicating lower insulin sensitivity in GDM. GHbA1c levels in GDM were within normal limits (5,10±0,6).

There was no difference in BMI between groups, before pregnancy (GDM: 24,76±1,3 vs NGT: 25,71±1,6) (p=0,66) as well as for the weight gained during pregnancy (GDM:13,58±1,6 vs NGT: 12,34±1,8 kg) (p=0,615). The placental superoxide dismutase levels were significantly lower in GDM than NGT (519,98±29,5 vs 671,17±49,1 μM) (p=0,028). In conclusion, the difference in the antioxidant biomarker level indicate that regardless the euglycemic condition in GD, there is an increased oxidative load and thus an exhaustion of the cell antioxidant capacity. These data may point toward a cellular pathway that may contribute in the higher prevalence of adverse outcomes in GD.

PS 107 Neuropathy - diagnostic tools

1111

Validity of DN4 as a screening tool for neuropathic pain of painful diabetic polyneuropathy

V. Spallone[1], R. Morganti[1], C. D'Amato[1], C. Greco[1], L. Cacciotti[1], S. Rotella[1], G. Marfia[2];
[1]Internal Medicine, Endocrinology, [2]Neurological Sciences, Neurology, Tor Vergata University, Rome, Italy.

Background and aims: Among the screening tools developed for distinguishing neuropathic from nociceptive pain, the DN4 (Douleur Neuropathique en 4 Questions) use both interview questions (DN4-interview) and limited bedside physical tests. DN4 has not been specifically validated in diabetes. This study was aimed at assessing the validity and diagnostic accuracy of DN4 as a screening tool in identifying neuropathic pain associated with painful diabetic polyneuropathy (PDPN).
Materials and methods: In 135 diabetic patients (age 53±16 years, diabetes duration 16±12 years, BMI 30±7 Kg/m^2, 68 male, 38 with type 1 diabetes), clinical parameters, symptoms and signs of diabetic polyneuropathy (DPN), the vibration perception threshold (VPT), the cold (CTT) and warm sensation thresholds (WTT), and neuropathic pain were evaluated using the Michigan Neuropathy Screening Instrument Questionnaire (MNSI-Q), the Michigan Diabetic Neuropathy Score (MDNS), the Biothesiometer, the Neuro Sensory Analyzer TSA-II, a pain history, an 11-point numerical rating scale (NRS), the Short-Form McGill Pain Questionnaire (SF-MPQ), the Brief Pain Inventory (BPI), and DN4 (the latter administered by "a blinded" investigator). PDPN was defined as the presence of DPN (at least 2 abnormalities among symptoms, signs, VPT, thermal thresholds, and 10 g monofilament) plus clinician-diagnosed chronic neuropathic pain with the same distribution as the neurological deficits and attributable to DPN.
Results: Forty-five patients fulfilled the criteria for PDPN (PDPN$^+$), 33 for DPN (DPN$^+$) and 57 were DPN free (DPN$^-$). The DN4 score was related to both neurological (Vs. MNSI-Q: rho=0.82, P<0.0001; Vs. MDNS: rho=0.62, P<0.0001; Vs. VPT hallux: rho=0.48, P<0.0001; Vs. number of 10 g monofilament correct answers: rho=-0.42, P<0.0001; Vs. CTT: rho=-0.28, P=0.0026; Vs. WTT: rho=0.31, P=0.0009) and neuropathic pain indices (Vs. 24h average pain NRS: rho=0.30, P=0.049; Vs. SF-MPQ sensory dimension: rho=0.56, P=0.0003; Vs. BPI pain now: rho=0.43, P=0.005; Vs. BPI general activity interference: rho=0.33, P=0.029; Vs. BPI mood interference: rho=0.32, P=0.033). Using ROC analysis, the DN4 score showed a high diagnostic accuracy in discriminating between PDPN$^+$ and both DPN$^+$ and DPN$^-$ (AUC: 0.95±0.02, 95% C.I. 0.91-0.98), as well as between PDPN$^+$ and DPN$^+$ or DPN$^-$ (AUC: 0.93±0.03 and 0.96±0.02, respectively). The DN4-interview score showed a similar diagnostic accuracy (AUC: 0.94±0.02, 95% C.I. 0.89-0.97). At the cut-off score of 4, DN4 displayed a sensitivity of 79%, a specificity of 92%, a positive predictive value of 84%, a negative predictive value of 89%, and a likelihood ratio for a positive result of 9.89. At the cut-off score of 3, DN4-interview displayed a sensitivity of 79%, a specificity of 85%, a positive predictive value of 74%, a negative predictive value of 88%, and a likelihood ratio for a positive result of 5.33.
Conclusion: This study demonstrates for the first time the diagnostic accuracy of DN4 in identifying neuropathic pain in PDPN and supports its usefulness as a screening tool for diabetic peripheral neuropathic pain. The DN4-interview has quite similar diagnostic accuracy as the full version of DN4 with the additional advantage of a possible use as a self-questionnaire.

1112

Neuropad and corneal confocal microscopy: new indicators for human diabetic neuropathy

M. Tavakoli, C. Quattrini, P. Begum, H. Fadavi, A.J.M. Boulton, R.A. Malik;
University of Manchester, United Kingdom.

Objectives: Evaluation of early nerve damage is important to define diabetic patients at risk of developing pain and foot ulceration. The earliest nerve damage occurs to the small fibres detected by skin biopsy. Corneal confocal microscopy (CCM) and the Neuropad test provide non-invasive structural (c-fibres) and functional (sympathetic cholinergic fibres) measures of small fibre damage and may act as screening tools for diabetic neuropathy.
Methodology: 100 diabetic patients (Type I/II: 61/39) and 14 healthy volunteers underwent assessment of neuropathic severity using the Neuropathy

disability score (NDS), vibration perception threshold (VPT), Neuropad assessment, and CCM.
Findings: All control subjects had a normal response to Neuropad (100% Pink). Patient response was classified into three groups: Normal response (100% Pink), Intermediate response (patchy pink), and abnormal response (100% Blue).

Demographic characteristics of the controls and patients according to the three categories of Neuropad responses.

	Controls	Diabetic Patients		
	Normal response	Normal response	Patchy response	Abnormal response
Number	14	31	43	26
Age (yrs)	48 ± 2.50	46 ± 3	53.5± 2	52± 2.50
Type diabetes (I/II)	-	19/12	22/21	20/6
Duration of diabetes (yrs)	-	15± 2.00	22.00± 2.00	21± 2.00
HbA1c (%)	<6.5	7.5 ± 0.3	7.9± 0.3	8.0 ± 0.5
NDS (0-10)	0	1.3±0.3	4.5±0.5	6.3±0.7
VPT(Hz)	6.5±0.4	10.5±1.1	19.4±1.8	28.5±3.1#
NFD (no/mm^2)	48.3±3.3	32.9±1.8#	25.0±2.1*	16.5±2.5*
NBD (no/mm^2)	30.1±1.4	17.0±2.1*	11.4±1.4*	7.8±1.7*
NFL (mm/mm^2)	9.7±0.7	6.0±0.6	4.3±0.4	3.0±0.6*

Post Hoc: v control *P<0.001, #P<0.05,

Diabetic patients with a normal NDS and VPT i.e. no neuropathy have a normal Neuropad response which becomes patchy in those with mild neuropathy and abnormal in those with more severe neuropathy. However, CCM abnormalities are present even in patients with no neuropathy and progressively worsen with increasing neuropathic severity. The Neuropad response correlated with NDS (rs=0.456, p= 0.000), VPT (rs= 0.330, p=0.000), NFD (rs=-0.365, p=0.000), NBD (rs=-0.377, p=0.000), and NFL (rs=-0.395, p=0.000).
Conclusion: Neuropad therefore detects mild neuropathy whilst CCM detects nerve damage at the very earliest stage. As both tests are non-invasive they offer considerable potential as screening tools.

1113

A simple method for detecting 'at risk feet' in hospitalised individuals with diabetes

P.R.J. Vas[1], N. Baker[1], C. Taylor[1], A.I. Adler[2], G. Rayman[1];
[1]The Diabetes Centre, Ipswich Hospital NHS Trust, [2]The Wolfson Diabetes and Endocrine Clinic, Cambridge University Hospitals NHS Foundation Trust, United Kingdom.

Background and aims: Approximately 3% of hospitalised individuals with diabetes develop a foot lesion during admission. Yet, care providers infrequently screen patients on admission for at-risk feet citing the unavailability of screening instruments. We wanted to assess a novel, simple, readily-available method - the touch test [TT] - to detect sensory neuropathy.
Materials and methods: The TT involves lightly touching with the operator's finger the dorsum of 1st and tips of 1st, 3rd, 5th toes bilaterally. We assessed the performance of monofilament [MF] and TT in 122 diabetic subjects against a vibration perception threshold of >25V from neurothesiometry in either foot. Assessments were performed by 8 individuals.
Results: MF and TT have similar and good sensitivity, specificity and operating characteristics. Applying the criterion of ≥2/8 insensate areas to signify neuropathy, the sensitivities and specificities for TT were 70% and 88% (MF 78% and 91%), The area under the curve for TT is 0.80 (MF, 0.85). Inter-rater agreement for TT indicated substantial agreement, Cohen's kappa (k) = 0.68.
Conclusion: This equipment-free test which is 'an arms length away' performs well against a recognised standard known to predict risk of ulceration. Health care providers should use this simple, handy test to assess all patients admitted with diabetes.

1114

Comparing skin biopsy with corneal confocal microscopy: diagnostic yield of nerve fiber density

C. Quattrini[1], M. Tavakoli[1], P. Kallinikos[1], A. Marshall[2], N. Efron[3], A.J.M. Boulton[1], R.A. Malik[1];
[1]University of Manchester, United Kingdom, [2]Department of Neurophysiology, Manchester, United Kingdom, [3]Institute of Health and Biomedical Innovation, Brisbane, Australia.

Background and aims: The assessment of intra-epidermal nerve fiber density (IENFD) in skin biopsies and corneal nerve fiber density (CNFD) using corneal confocal microscopy (CCM) provides promising techniques to detect small nerve fiber damage in patients with peripheral neuropathy. To help define the clinical utility of each of these techniques in patients with diabetic neuropathy we have assessed sensitivity and specificity of IENFD and CNFD in predicting the following: 1) diabetic polyneuropathy (DPN); 2) risk of foot ulceration (RFU); 3) initial small fiber neuropathy (iSFN); 4) severe small fiber neuropathy (sSFN).
Materials and methods: 55 diabetic patients underwent assessment of neuropathic deficits using neuropathy disability score (NDS), nerve conduction studies, vibration perception threshold (VPT) using the Neurothesiometer, cooling detection threshold (CDT), minimal heat-as-pain threshold (0.5 HP-VAS) and autonomic function testing (DB-HRV) using the CASE IV. Definition of DPN was: 1) NDS ≥ 3/10, 2) peroneal motor nerve conduction velocity (PMNCV) ≤ 42 m/sec, 3) at least one positive small fiber assessment among DB-HRV≤5th pc, CDT≥95th pc, HP-VAS≥95th pc (CASE IV normality range); 4) VPT ≥ 15 V. Definition of RFU was: 1) NDS ≥6/10, 2) VPT ≥25, and one among the following: PMNCV ≤35 m/sec, CDT ≥98th pc, HP-VAS ≥98th pc, DB-HRV ≤3rd pc. Definition of iSFN was: any value outside the 5th - 95th pc range (whichever end of the distribution applied) for CDT, 0.5 HPVAS and DB-HRV Definition of sSFN was: all values outside the same range for all available CDT, 0.5 HPVAS and DB-HRV. All patients then underwent skin biopsy to quantify IENFD and CCM to quantify CNFD.
Results: The sensitivity of IENFD in diagnosing DPN was 78%, RFU-88%, iSFN-69% and sSFN-86% with respective specificities of 56%, 54%, 63% and 46%. The sensitivity of CNFD in diagnosing DPN was 56%, RFU-63%, iSFN-50% and sSFN-86% with respective specificities of 75%, 72%, 84% and 69%.
Conclusion: Although the sensitivity for detecting different severities of DPN is greater for IENFD compared to CNFD, the specificities for the latter are greater. Specifically for detecting SFN, CNFD has a comparable and high sensitivity but higher specificity than IENFD. However, the major advantage of CCM is that it is a non-invasive technique.

1115

Extensor digitorum brevis muscle atrophy in diabetic patients

M. Baba, C. Suzuki, M. Tomiyama, A. Arai, Y. Miki, H. Nishijima, T. Ueno, R. Haga;
Department of Neurology, Aomori Prefecture Medical Centre, Aomori-City, Japan.

Background and aims: Diabetic polyneuropathy is clinically sensory dominant. However, electrophysiological assessment *i.e.* F-wave latency study indicates early motor fibre involvement even in an asymptomatic patient. We assessed atrophy of extensor digitorum brevis (EDB) muscle in diabetic patients, whether this small foot muscle atrophy has diagnostic value for diabetic polyneuropathy or not.
Materials and methods: We examined EDB muscle atrophy and other neuropathic signs in 42 diabetic patients, and score of the michigan neuropathy diagnostic instruments (MNDI) was assessed. Motor and sensory nerve conduction studies were carried out in the tibial, peroneal and sural nerves bilaterally. The EDB muscle atrophy was graded as follows: Grade 0; no atrophy, Grade I: just wasted and visible, Grade II; palpable or visible by toes dorsiflexon, Grade III; neither palpable nor visible.
Results: EDB muscle atrophy was clearly and easily detectable by inspection and palpation. Number of patients of each group was as follows: G-0; 7, G-I; 15, G-II; 13, G-III; 7. Average scores of MNDI are: G-0; 2.4, G-I; 3.5, G-II; 3.7, G-III; 3.9. CMAP amplitudes of EDB after giving supramaximal electric shock to the deep peroneal nerve at the ankle are: G-I; 2.9mV, G-II; 1.4mV, G-II; 0.9mV, G-III; 0.3mV. Distal latency time and MCV were most abnormal in G-III. CMAP of the abductor hallucis muscle evoked by the tibial nerve stimulation and CSAP of the sural nerve were as follows, respectively: G-0; 10.5mV, 6.2uV, G-I; 8.0mV, 5.8uV, G-II; 7.9mV, 6.0uV, G-III; 2.9mV, 2.3uV.

Distal latency, MCV and Minimal F-wave latency of the tibial nerve, and SCV of the sural nerve were markedly delayed in G-III patients.
Conclusion: EDB muscle atrophy well reflects clinical and electrophysiological severity of diabetic polyneuropathy, and appears to be a simple and useful sign indicating progressive motor fibre loss in diabetic polyneuropathy.

1116

Spinal cord atrophy and thalamic neuronal dysfunction in distal symmetrical diabetic polyneuropathy

I.D. Wilkinson[1], D. Selvarajah[2], R. Gandhi[2], C. Emery[2], S. Tesfaye[2];
[1]Academic Unit of Magnetic Resonance Imaging, University of Sheffield, [2]Diabetes Research Department, Royal Hallamshire Hospital, Sheffield, United Kingdom.

Central nervous system involvement in diabetic sensorimotor neuropathy (DN) is being increasingly recognised. We have previously demonstrated the presence of spinal cord atrophy not only in subjects with established-DN but also in early, subclinical DSP. In a further proton magnetic resonance spectroscopy (H^+MRS) study, subjects with established-DN were found to exhibit thalamic neuronal dysfunction. In this study we looked at the relationship between spinal cord atrophy and thalamic neuronal function in DSP.
Methods: Twenty subjects [6 healthy volunteers; 14 diabetic subjects (8 No-DN and 6 Established-DN)] underwent detailed assessment of peripheral nerve function including: neuropathic symptom evaluation, clinical examination to determine the Neuropathy Impairment Score of Lower Limbs (NIS[LL]), 5 attributes of nerve electrophysiology, vibration detection threshold and heart rate with deep breathing test. MR imaging of the cervical spine and thalamic H-MRS were conducted within one year. Cervical cord cross-sectional area at disc level C2/C3 was calculated. Established markers of neuronal function [N-acetyl aspartate:choline (NA:Cho)] were obtained from the thalamus using long echo time H^+MRS.
Results: There was no significant difference in subgroup demographics [age: HV 42.5(15.4), No-DN 42.8(8.7), and Established-DN 48.4 (11.3)]. NIS[LL]+7 test score was significantly higher in subjects with Established-DN [21.8(15.2)] compared with No-DN [1.14(1.07); $p<0.05$]. Subjects with Established-DN had significant reduction in both cervical cord area [ANOVA p=0.002; Established-DN mean(SD) 52.1(4.1) vs No-DSP 68.8(8.20), p=0.001 and Established-DN vs HV 68.7(10.4), p=0.002] and thalamic NA:Cho [ANOVA p=0.013; Established-DN 1.58(0.16) vs No-DN 1.80(0.15) and Established-DN vs HV 1.74(1.0)] compared to the other groups. Among subjects with diabetes, cervicalcord area was significantly related to thalamic NA:Cho (r=0.42, p=0.04).
Conclusion: Diabetic subjects with Established-DN had the greatest level of spinal cord atrophy and thalamic neuronal dysfunction compared those with No-DN and HV. Significant positive correlations between spinal cord area and thalamic NA:Cho suggest progressive, concomitant involvement of the central nervous system in DN. The pathophysiological insult on the nervous system caused by DN appears more generalised, involving both the peripheral and central nervous systems.
Supported by: Diabetes UK

Symptomatic neuropathy in type 1 diabetes is preceded by subclinical electrophysiological abnormalities - a prospective study

N. Alstrand[1], J. Ludvigsson[2], L. Hyllienmark[3], J. Wahlberg[1];
[1]Department of Medical and Health Sciences, Division of Internal Medicine, Faculty of Health Sciences, Linköping, [2]Department of Clinical and Experimental Medicine, Division of Pediatrics, Faculty of Health Sciences, Linköping, [3]Department of Clinical Neuroscience, sections of Neurology and Clinical Neurophysiology, Karolinska Institutet, Stockholm, Sweden.

Background and aims: It is assumed that overt neuropathy with symptoms is preceded by a subclinical form which can be detected by studies of nerve conduction velocity. However, long-term studies in patients with type 1 diabetes with multiple insulin-injection therapy are lacking. The aim of the study was to elucidate if subclinical electrophysiological abnormalities can predict symptomatic neuropathy in patients with type 1 diabetes.
Materials and methods: Fifty-nine patients with type 1 diabetes were examined twice, 43 already in year 1994, and 16 in year 2000. From onset of diabetes all patients were treated with multiple insulin-injection therapy. Duration of diabetes at the second examination was 20.1 +/- 5.4 (range 10-31) years. The first examination included motor nerve conduction velocity (MCV), compound muscle action potential (CMAP) in peroneal and median nerves and sensory nerve conduction velocity (SCV) and nerve action potential (SNAP) in sural and median nerves. The second examination included also assessment of quantitative sensory thresholds (QST), neuropathy impairment assessment (NIA) and neuropathy symptom assessment (NSA). Symptomatic neuropathy was defined as NSA of ≥ 1.
Results: At the second examination symptomatic neuropathy was found in 12/ 59 (20%) of the patients. Those with symptoms on follow-up had lower peroneal and median MCV at baseline compared to those without symptoms ($p < 0.05$ for both parameters). In a logistic regression model, baseline long-term HbA1c and baseline median MCV predicted symptoms of neuropathy at follow-up. A decrease in peroneal MCV by more than two standard deviations at baseline significantly increased the risk of symptomatic neuropathy (OR=17; $p < 0.03$) A combination of both long term HbA1c ≥ 7.0 and a baseline decrease in peroneal MCV (≥ 2 SD) increase the risk of future symptoms (OR=21; $p<0.000$). In addition, the decrease in peroneal MCV at baseline showed a positive correlation with all parameters of nerve conduction at follow up ($p < 0.003$).
Conclusion: Despite multiple insulin-injection therapy symptomatic neuropathy is seen in 20 percent of patients after 20 years of type 1 diabetes. Overt diabetic neuropathy with symptoms is preceded by a subclinical form detectable by studies of nerve conduction.

PS 108 Somatic neuropathy - clinical observations

1118

Significant impact of mood disturbances on pain perception in painful DPN: time to re-evaluate current practice?

A. Sankar[1], D. Selvarajah[2], R. Gandhi[2], M. Oleolo[2], C. Emery[2], S. Tesfaye[2];
[1]Diabetes Research Department, University of Sheffield, [2]Diabetes Research Department, Royal Hallamshire Hospital, Sheffield, United Kingdom.

Painful diabetic peripheral neuropathy (DN) is common and has a negative impact on mood, functionality and quality of life. Unfortunately, current clinical practice focuses on pharmacological interventions directed at pain relief without adequate assessment of mood. An understanding of the impact of mood disorders on pain reporting and perception may result in better characterisation of the pain experience and patient tailored management strategies.
Method: 60 patients with painful DPN [mean age: 56.5(10.2), male:61%, type 2 DM: 79.7%] underwent: 1) clinical examination and nerve conduction studies to quantify DPN; 2) assessment of pain intensity with Neuropathic Pain Scale (NPS) and 3) assessment of mood with Hospital Anxiety and Depression Scale, Pain Acceptance Questionnaire (CPAQ) and Pain Catastrophising Scale (PCS). Based on these assessments on subjects that had been referred to our tertiary, specialist painful DN clinic were found to have severe symptoms [diabetes duration: 13.9(8.3), pain intensity VAS: 7.2(2.1)].
Results: All subjects had moderate to severe painful DPN with group average NIS(LL) + 7 test score of 26.9(14.1). There was a high prevalence of mood disturbance with 70% suffering with either anxiety and/or depression. The presence of anxiety appears to result in reporting a greater variety of pain [anxiety vs no anxiety, NPS: 5.3(1.8) vs 4.3(1.1); p=0.03] and significantly higher pain scores [NPS: 6.2(1.9) vs 4.6(2.2); p=0.002]. However, subjects who were depressed were less likely to accept pain [CPAQ depression vs no depression, pain willingness: 20.6(11.8) vs 40.0(14.9); p=0.009] and engage in social and/or physical activity [CPAQ, activities engagement: 29.0(11.8) vs 46.1(18.3); p=0.04]. Anxiety [PCS: 5.2(3.0) vs 2.0(1.5); p=0.03] and depression [PCS: 5.4(2.8) vs 1.9(1.7); p=0.01] both result in a significant magnification of symptoms.
Conclusion: This study found a very high prevalence of mood disorders in patients with severe painful DN. It also highlights the differing but significant impacts of anxiety and depression on an individual's pain experience. As we have quick and simple screening tools and effective treatments for mood disorders, an appreciation/assessment of the psychological impact of mood on pain may lead to better clinical outcomes for sufferers.

1119

Prevalence of painful diabetic neuropathy and quality of life in patients with type 1 or type 2 diabetes mellitus in specialist care

K. Algür, H.W. de Valk;
Department of Internal Medicine, University Medical Centre Utrecht, Netherlands.

Background and aims: Chronic painful distal neuropathy (CPDN) is a major complication in diabetes mellitus. However, little is known about prevalence, severity, determinants and impact of CPDN on quality of life. This information is necessary to improve care of patients as well as to design preventive strategies and evaluate current and future therapies. In this observational study we assessed prevalence and effect on quality of life in patients with CPDN in one large hospital in the Netherlands.
Materials and methods: A total of 720 patients with either type 1 (DM1, n=334)) or type 2 (DM2, n=386)) attending the out-patient clinic for Diabetology of the University Medical Centre Utrecht received a set of questionnaires by mail. Response rate in DM1 was 50.6% and in DM2 51.0%. Questionnaires sent were pain visual analogue scale (0-10 point VAS), a 0-100 rating scale of quality of life on the day of the questionnaire (S100) and 3 quality of life (QoL) questionnaires (Euro-QoL EQ-5D, QoL-Enjoyment and satisfaction, and Medical outcomes study sleep scale). Other study data were collected from medical records. A diagnosis of CPDN was established when vibration sense at the level of the hallux was diminished or absent in combination with a VAS-score ≥4. No obvious other causes of painful neuropathy (severe alcoholism, inflammatory nerve damage, untreated B12 deficiency) were present.
Results: Mean age DM1 44.1±12.9, DM2 61.9±12.6 years (p<0.001); duration of disease DM1: 25.9±14.7, DM2: 15.0±8.3 years (p<0.001); males: DM1: 43.5; DM2: 60.2% (p<0.01); 93.4% patients with DM2 on insulin. Prevalence of CPDN in DM1 was 13.4% and 26.6% in DM2 (p<0.001). Both in DM1 and DM2, CPDN had a major, statistically highly significant (p<0.001) negative effect on daily activities, mood and well-being, professional activities, domestic and family activities, social relations, sexual activities as well as on sleep quality. S100 was 57.6±19.3 with pain and 77.0±16.5 without pain in DM1 (p<0.001); percentages in DM2 50.9±18.8 and 70.2±18.8 (p<0.001). S100 was significantly higher in DM1 than in DM2 in subjects without CPDN whereas S100 was comparable between DM1 and DM2 with CPDN.
Conclusion: In conclusion, chronic painful distal neuropathy is a common feature in both type 1 and type 2 diabetes, significantly more so in DM2 compared to DM1 and has a major negative influence on all aspects of quality of life. Quality of life constitutes a major effect parameter.

1120

BMI and nerve dysfunction in diabetic patients

C.N. Manes, T. Exiara, M. Psallas, G. Tsiantas, D. Skoutas;
Diabetes Center, Teaching Hospital "PAPAGEORGIOU", Thessaloniki, Greece.

Background and aims: Recent epidemiological studies have found a strong correlation between diabetic neuropathy and body weight. Furthermore small fiber neuropathy tends to develop within a few years of diabetes as relatively early complication. Early recognition of potentially modifiable risk factors for diabetic neuropathy - a known risk factor for foot ulcers - is crucial if we are to succeed in prevention of diabetic foot lesions. The aim of the present study was to investigate the relationship between BMI (modifiable risk factor) and small and overall nerve fiber dysfunction in diabetic patients.
Materials and methods: 278 consecutive diabetic patients (type 2) were investigated. Males=147, Mean age (yrs) was 63,31±11,25, Mean duration of diabetes (yrs) 12,85±8,56. The Neuropathy Disability Score (sensory signs) was used to identify those patients with overall nerve dysfunction (NDS≥3: abnormal). The sum of deficits of pain and cold sensation was used to identify any impairment of small fiber dysfunction (NDS_1≥2: abnormal). BMI was calculated as usual (kg/m^2). Statistical analysis was performed in a univariate and multivariate model (level of significance 0,05).
Results: 1) BMI<25 (NDS_1: 0,4±0,3), 25<BMI<29 (NDS_1: 0,53±1,05), BMI≥30 (NDS_1: 1,04±1,01). p<0,05 for every comparison between two groups. Correlation between BMI and NDS_1 was significant (p: 0,05 r^2:0,026). 2) BMI<25 (NDS: 0,7±0,8), 25<BMI<29 (NDS: 1,1±0,9), BMI≥30 (NDS: 2,01±2,0). p<0,05 for every comparison between two groups. Correlation between BMI and NDS was also significant (p: 0,05 r^2:0,026). 3) In the multivariate analysis BMI and duration of Diabetes were significant factors for overall nerve dysfunction (p<0,05).
Conclusion: The present study shows that nerve fiber dysfunction is also associated with the body weight e.g. elevated BMI. This finding supports the role of other factors (modifiable) apart from the already known in the pathogenesis and progression of diabetic neuropathy and prevention of foot ulcers. Larger studies are needed to confirm this finding.

1121

Association between peripheral nerve function and bone mineral density in patients with type 2 diabetes mellitus

W. Wang, Y. Xie, D. Yu;
Diabetic neuropathy department, Metabolic Disease Hospital of Tianjin Medical University, China.

Background and aims: To investigate the association between peripheral nerve function and bone mineral density (BMD) in patients with type 2 diabetes mellitus(T2DM).
Materials and methods: A total of 169 patients with type 2 diabetes were enrolled. All the patients were tested with fasting blood glucose (FBG), postprandial 2h blood glucose (P2BG), hemoglobin A1c (HbA1c), triglycerides, cholesterol, urinary albumin excretion,serum , serum calcium, serum phosphorus, serum magnesium, serum bone alkaline phosphatase isoenzyme . Lumbar and hip BMD were measured by dual-energy X-ray absorptiometry and according to the T-score ,all the patients were categorized into the osteoporosis group (T-score≤-2.5), the osteopenia group(-2.5<T-score≤-1)and the control group(-1< T-score≤1). The factor affecting T-score was analyzed

too. Nerve function was assessed by 10-g monofilament detection, vibration threshold, and bilateral sural nerve amplitude(CMAP) and conduction velocit(NCV) y, peroneal amplitude and NCV on the dominant side, and median motor and sensory amplitudes and NCVs on the nondominant side.
Results: Among the female patients, a higher proportion of postmenopausal women in osteoporosis group compared with controls(P<0.05). Patients with osteoporosis had older age(P<0.05) and longer T2DM duration (P<0.05) than control group both in male and female patients .No difference of the parameters of laboratory was seen among the groups, while, except the parameter of bone metabolism, B-ALP was elevated in osteoporosis group compared with controls . monofilament detection, and peroneal NCV) and CMAP were significantly lower in Patients with osteoporosis as well as the vibration threshold was significantly higher in them compared with control group. Relative analysis showed that the lumbar spine and hip BMD of T2DM group had negative correlation with age, duration menopause, severity of diabetic neuropathy and positive correlation of B-ALP . After adjusting for age, diabetic course, B-ALP, menopause, poor nerve function (lower nerve conduction amplitude and velocity) was associated with lower T-score of both lumbar spine and hip BMD significantly.
Conclusion: Lower BMD was associated with poor peripheral nerve function (both sensory nerve and motor nerve) in the type 2 diabetes mellitus, diabetic neuropathy was an independent risk factors of osteoporosis inT2DM. The pathophysiological mechanisms of bone metabolism and diabetic neuropathy should be the concern of further research.

1122

High prevalence of vitamin D deficiency in type 2 diabetic patients with neuropathy

S. Skalli[1,2], M. Muller[1], S. Pradines[1], S. Halimi[1], N. Wion-Barbot[1];
[1]Diabetology Department, [2]Pharmacy Department, CHU Grenoble, France.

Background and aims: The pro-inflammatory profile (IL-6, TNF-α, IL-1, IL-8) in monocytes from type 2 diabetic patients is down-regulated by 1,25(OH)2D3, and levels of acute-phase proteins are significantly associated with neuropathic deficits in diabetic patients. Several studies have demonstrated alterations in vitamin D metabolism in those patients and adverse outcomes associated with vitamin D insufficiency have been described in the human musculoskeletal, innate immune, and cardiovascular systems. We report a pilot study assessing the relationship between peripheral neuropathy in type 2 diabetic patients and vitamin D depletion.
Materials and methods: We conducted a prospective and observational study of 111 consecutive type 2 diabetic patients ambulatory treated in Diabetology Department between January and April 2009. Subjects were tested for deep tendon reflexes at patella, and Achilles, sensory loss using vibration perception with 128-Hz tuning fork by the on-off method, and pressure perception with 10 g Semmes-Weinstein monofilament. Exclusion criteria were neuropathy from other etiologies (e.g., familial, alcoholic, nutritional and uremic) and vitamin D supplementation. Following data were recorded: Age, body mass index (BMI), glycated haemoglobin (HbA1c), duration of diabetes, peripheral neuropathy status (PN), intact serum parathyroid hormone (PTH), serum 25-OH vitamin D (25OHD) concentration, total serum calcium concentration and serum creatinine.
Results: Overall, 111 patients were evaluated and the majority (55.85%) of them had peripheral neuropathy. Patients with PN were significantly older, 70.58±10.85 vs 57.57±12.27 years respectively (p<0.0001) and had significantly longer diabetes duration, 17.61± 9.52 vs 10.21±6.97 years respectively (p<0.0001). No significant differences were observed in BMI and HbA1c. Significantly decreased 25OHD levels were found in the PN group, 24.6±11.98 vs 34.74±17,26 nmol/l (p<0.0001). Frank vitamin D deficiency rate (25OHD < 50 nmol/l or 20 ng/ml) was significantly higher in PN group, 95% vs 79,5% (p<0,05). Vitamin D insufficiency rate (25OHD between 50-75 nmol/l or 20-30 ng/ml) did not differ significantly between the two groups 5% in the PN group vs 16.5%. PTH levels and creatininemia were significantly increased in the PN group (p<0.05).
Conclusion: In type 2 diabetic patients, peripheral neuropathy is associated with significantly lower levels of 25OHD. Although these data do not prove the existence of a causal link between vitamin D deficiency/insufficiency and PN, they have major clinical and therapeutic implications for the management of PN. Vitamin D-deficient status potentially increases risk of non vertebral and hip fracture in this older population with muscle weakness at higher risk for falls. Vitamin D deficiency/insufficiency also decreases antibacterial responses in this PN population at higher risk for foot ulcers. On the other hand, the importance of the Nerve Growth Factor, which is up-regulated by Vitamin D, has been established in the development of diabetic PN using diabetic animal model. Further studies are needed to understand the causes and to investigate the clinical significance of vitamin D replacement therapy in PN diabetic patients. Determining what is the adequate vitamin D level for PN diabetic patients and how much supplementation is necessary is now a matter of crucial concern in the management of diabetic PN.

1123

Association between symptoms of neuropathy, nerve conduction and levels of heat shock protein 27 in type 2 diabetes

K. Pourhamidi[1], L.B. Dahlin[2], O. Rolandsson[1];
[1]Family Medicine, Department of Public Health and Clinical Medicine, Umeå University, [2]Department of Clinical Sciences Malmö – Hand Surgery, Skåne University Hospital, Lund University, Malmö, Sweden.

Background and aims: Increased levels of serum HSP27 (sHSP27) are associated with distal symmetric polyneuropathy (DSPN) in type 1 diabetic patients. However, the association between nerve function and sHSP27 has not been studied in subjects with type 2 diabetes (T2D) and impaired glucose tolerance (IGT). Thus, our objectives were to investigate the association between nerve conduction in the legs, symptoms of distal polyneuropathy and sHSP27 levels.
Methods: Subjects were consecutively recruited from the population-based Västerbotten Intervention Program; controls (n=39, m/f=19/20, mean age=61± 0.6 years), IGT (n=29, m/f=15/14, mean age=61± 0.8 years), T2D (n=51, m/f=30/21, mean age=61± 1.3 years). Nerve conduction studies were performed. Z-scores for motor conduction velocity (CV) of the peroneal nerve, and the sensory CV and amplitude of the sural nerve were measured and compiled into a composite Z-score of the right leg (Z-score leg). Neurological Disability Score (NDS), including examination of sensory perception, reflexes and muscle strength, were used to evaluate symptoms of neuropathy in the leg. NDS and Z-score leg were categorized into tertiles, respectively. sHSP27 levels were measured and divided into low and high levels.
Results: Subjects in the highest NDS tertile had lower sHSP27 levels (328 ± 287 pg/mL) compared to subjects in the lowest NDS tertile (558 ± 404 pg/mL, p=0.04). Subjects in the lowest tertile of Z-score leg were in the lowest sHSP27 group (63%) compared to the subjects in the highest group (38%, p=0.034). The highest tertile of Z-score leg was associated with high levels of sHSP27 (OR 3.8, 95% CI 1.2; 11.5, p=0.02); adjusted for age and sex. However, this association was attenuated when adjusted for T2D status (OR 3.1, 95% CI 0.9; 9.9, p=0.06).
Conclusion: In summary, increased sHSP27 levels were associated with an increasing Z-score of the leg; thus, a better nerve conduction, and fewer symptoms using the whole study population. The attenuation of the association when including diabetic status indicates an altered HSP27 production in T2D patients compared to controls and subjects with IGT.

1124

The relationship between brachial-ankle pulse wave velocity and peripheral neuropathy in type 2 diabetes

J.Y. Park[1], C.W. Lee[1], B.H. Kim[2], J.Y. Mok[2];
[1]Internal medicine, Busan St. Mary's Medical Center, [2]Internal medicine, Pusan national university school of medicine, Busan, Republic of Korea.

Background and aims: Brachial-ankle pulse wave velocity (baPWV) has been shown to be a good surrogate marker of clinical atherosclerosis. The aim of the study was to determine the relationship between baPWV and peripheral neuropathy in patients with type 2 diabetes.
Materials and methods: We assessed 692 patients with type 2 diabetes (314 men, 376 women, mean age 56.9 ± 10.9 years, mean diabetes duration 7.9 ± 6.3 years). The intensity of neuropathic symptoms (pain, burning sensation, paresthesia, and numbness) was scored according to numeric visual analog scales. The total symptom score was calculated from the sum of each neuropathic symptom scores. The neurological assessment (ankle reflexes and 10-g monofilament test) was performed. The baPWV was measured using an automated device.
Results: In bivariate correlation analysis, the presence of peripheral neuropathy (increased total symptom scores or abnormal neurological assessment) was significantly correlated with maximal baPWV (r =0.127, p < 0.01), age (r =0.119, p < 0.01) and sex (r =0.128, p < 0.01). After analysis using independent t- test, the patients with peripheral neuropathy had higher maximal

baPWV, systolic blood pressure and subject number of female sex and older age compared with control (Table).
Conclusion: Peripheral neuropathy was significantly correlated with baPWV in patients with type 2 diabetes.

Comparison of anthropometric characteristics of diabetes with and without peripheral neuropathy

Variables	DPN (n = 253)	Control (n = 439)	*P*-value
Age (years)	59 ± 11	56 ± 11	< 0.01
Male (%)	63 ± 5	50 ± 5	< 0.01
Diabetes duration (years)	8.5 ± 7.1	7.6 ± 5.8	NS
Height (m)	1.6 ± 0.1	1.6 ± 0.1	NS
Weight (kg)	64 ± 10	64 ± 10	NS
Systolic BP (mmHg)	139 ± 21	135 ± 17	< 0.01
Diastolc BP (mmHg)	82 ± 12	81 ± 9	NS

Dyslipidaemia and peripheral prediabetic neuropathy
U.A. Julius[1], Y. Maksimchyk[2], P. Watcho[2], S. Lupachyk[2], I.G. Obrosova[2];
[1]Medizinische Klinik III, Universitätsklinikum Dresden, Germany,
[2]Pennington Biomedical Research Center, Louisiana State University System, Baton Rouge, USA.

Background and aims: Evidence for the presence of diabetes-like neuropathy at prediabetic stage, prior to development of overt hyperglycemia, is emerging from both experimental and clinical studies. Until now, it has not been sorted out whether prediabetic neuropathy results from glucose intolerance, or other factors such as impaired insulin signaling, hypertriglyceridemia, hypercholesterolemia, and/or increased fatty acid concentrations come into play. This study was aimed at evaluating relative roles of the afore-mentioned factors in peripheral nerve function in prediabetic condition.
Materials and methods: Experiments were performed in Zucker lean and Zucker fa/fa rats, a model of prediabetes and obesity. Zucker fa/fa rats of 16 wks of age displayed obesity, glucose intolerance, hyperinsulinemia, hypercholesterolemia, and increased serum NEFA concentrations. They developed sensory nerve conduction velocity (SNCV) deficit and small sensory nerve fiber dysfunction manifest by thermal and mechanical hypoalgesia and tactile allodynia.
Results: In the Zucker fa/fa rats, a 4-wk treatment with the niacin derivative acipimox significantly reduced serum insulin ($p < 0.01$), NEFA ($p < 0.05$), and triglyceride concentrations ($p < 0.01$) without affecting impaired glucose tolerance and total and VLDL-LDL cholesterol concentrations. It also reversed SNCV deficit ($p < 0.01$) and alleviated small sensory fiber neuropathy.
Conclusion: Our findings suggest that impaired insulin signaling, hypertriglyceridemia, and/or increased fatty acids, but not impaired glucose tolerance or hypercholesterolemia are responsible for development of prediabetic neuropathy. The latter provides rationale for new early stage interventions, to stop progression of this devastating diabetic complication.

1126

Effects of long-term administration of moderate amounts of insulin on small and large peripheral nerve fiber function and structure in non-diabetic Wistar rats
K. Sugimoto[1], K. Kojima[1], M. Baba[2], M. Yasujima[1];
[1]Laboratory Medicine, Hirosaki University, [2]Neurology, Aomori Prefectural Central Hospital, Japan.

Background and aims: Insulin exerts neurotrophic and neuroprotective effects on peripheral nerves. In animal models of insulin deficient type 1 diabetes, trace amounts of insulin can ameliorate small and large peripheral nerve fiber dysfunction without influencing the level of glycemia. On the other hand, we have reported that chronic hyperinsulinemic hypoglycemia caused by insulinoma leads to peripheral nerve microangiopathy and large fiber degeneration in non-diabetic rats. Here we aim to investigate the effect of chronic treatment with moderate amounts of insulin on small and large peripheral nerve fiber function and structure in non-diabetic rats in the absence of severe hypoglycemia.
Mterials and methods: Sustained-release insulin pellets were subcutaneously implanted in 10-wk-old non-diabetic male Wistar rats (Ins-rats; n = 17) and delivered 2 to 4 IU/day of insulin continuously to these animals for 14 wks (14Ins-rats; n = 9) or for 30 wks (30Ins-rats; n = 8). Small and large peripheral nerve fiber function and structure of these animals were investigated using behaviorial, histologic and electrophysiological analysis. Age- and sex-matched untreated Wistar rats served as controls (14C-rats; n = 8 for 14 wks, 30C-rats; n=8 for 30 wks).
Results: Both 14Ins-rats and 30Ins-rats showed occasional mild to moderate reduction in blood glucose level of no less than 2.4 mmol/l during the observation period. Final HbA1c level was decreased by 13% ($p < 0.0005$) in 14Ins-rats and by 7% ($p < 0.005$) in 30Ins-rats compared with controls. Final body weight and serum insulin levels did not differ between 14Ins-rats and 14C-rats, whereas final body weight increased by 14% ($p < 0.005$) and serum insulin level increased by 104% ($p < 0.05$) in 30Ins-rats compared with 30C-rats. Behavioral analysis revealed unmyelinated nociceptive fiber dysfunction, as indicated by an 11 to 26% increase in tail flick latency to noxious heat stimulus ($p < 0.05$), until 14 wks after insulin treatment in 14Ins-rats compared with 14C-rats. We also found a 9 to 21% increase in tail flick la-

tency ($p < 0.05$) between 12 and 16 wks after insulin treatment in 30Ins-rats compared with 30C-rats. Final intraepidermal nerve fiber (unmyelinated) density was marginally decreased ($p = 0.057$) in 14Ins-rats compared with 14C-rats (mean ± SE; 47.7 ± 4.5/mm vs 60.0 ± 3.8/mm) and was unchanged in 30Ins-rats compared with 30C-rats (40.4 ± 6.7/mm vs 40.1 ± 4.7/mm). In contrast, final electrophysiological analysis of the sciatic-tibial nerve showed unchanged sensory (SNCV) and motor nerve conduction velocities (MNCV) in 14Ins-rats compared with 14C-rats, while SNCV increased by 10% ($p < 0.05$) and MNCV by 11% ($p < 0.01$) in 30Ins-rats compared with 30C-rats. The increased nerve conduction was associated with a 12% increase ($p < 0.05$) in myelinated fiber density in the tibial nerve in 30Ins-rats compared with 30C-rats.

Conclusion: Treatment of non-diabetic rats with moderate amounts of insulin, without causing severe hypoglycemia, appeared to induce transient unmyelinated (small) fiber dysfunction and loss for periods up to 16 wks, and led to increased myelinated (large) fiber function and density for the more extended period of 30 wks. These functional and structural changes in small and large peripheral nerve fibers merit further investigation to elucidate the mechanism whereby insulin exerts its effects on peripheral nerves.

1127

The comparison of peripheral nerve damage according to the glucose control period in the experimental diabetes

J. Heung Yong, K.A. Lee, J.H. Park, T. Park, H. Baek;
Chonbuk National University, JeonJu, Republic of Korea.

Background and aims: Besides just tight glucose control, early intensive therapy has been reported to be more important for the prevention of diabetic micro-and macro-complication. However, it was not known exactly about the quantitative difference according to the timing delay in the glucose control and whether early period control is really better than late control in the diabetic peripheral neuropathy. Therefore, in this study we investigated the effect of timing difference in glucose control on the peripheral nerves in the course of diabetes.

Materials and methods: The five groups (6-8 number in each group) comprised : Normal glucose rats (Normal), rats with hyperglycemia (designated: DM), rats with glucose control for entire 28-week period (designated: INS (W0-28)), rats with glucose control for early 14-week period followed by hyperglycemia for late 14 weeks (designated: INS (W0-14)), and rats with hyperglycemia for early 14 weeks followed by glucose control for late 14-week period (designated: INS (W15-28)).

Results: In the results, the current perception threshold (CPT) was more reduced in INS (W0-28) and INS (W15-28) group compared with INS (W0-14) or DM group (*P<0.05*). Mean myelinated axon area was larger significantly in INS (W0-28) and INS (W15-28) group (63.5±2.32 and 60.1±2.14 um) than INS (W0-14) or DM group (55.5± 2.81 or 51.5± 2.64 um) (*P<0.05*) and intraepidermal nerve fibers (IENF) density was less reduced significantly INS (W0-28) and INS (W15-28) group (6.9±0.46 and 6.8±0.11) than INS (W0-14) or DM group (5.9.5± 0.32 or 5.3± 0.39) (*P<0.05*). More increased trend of nerve fiber quantity was also observed in INS (W0-28) group than INS (W15-28) group although there was no significant difference.

Conclusion: Our results indicate that continuous glucose control is necessarily important to alleviate the peripheral nerve damage and moreover poor glycemic control during the later period prone to aggravate the neuropathy is more harmful than inappropriate early period management. Therefore, besides earlier management, the importance of continuous glucose control including later period of diabetes should also be emphasized in the diabetic peripheral neuropathy.

1128

Amelioration of diabetic enteropathy in chronic experimental diabetic rats transplanted with autologous adipose-tissue-derived mesenchymal stem cells

H. Mizukami[1], K. Takahashi[1], K. Sugimoto[2], M. Baba[3], S. Yagihashi[1];
[1]Department of Pathology and Molecular Medicine, Hirosaki University Graduate School of Medicine, [2]Department of Laboratory Medicine, Hirosaki University Graduate School of Medicine, [3]Department of Neurology, Aomori Prefectural Central Hospital, Japan.

Background and aims: Gastroenteropathy is a serious complication of diabetes and impairs quality of life, leading to bleak prognosis in diabetic patients. There is no effective treatment for this serious disorder. Cell therapy using adipose-tissue derived mesenchymal stem cells (ADSC) is now a promising approach for the reparative therapy and we applied ADSC to enteropathy in chronic diabetic rats.

Materials and methods: Streptozotocin-induced diabetic rats with 16 wk-duration were transplanted with autologous ADSC ($x10^6$), retrieved from subcutaneous region prior to diabetes onset, into the serosa of terminal ileum. After 6 wk observation period, thickness of mucosal villi, mRNA expressions of various growth factors and neuronal nitric oxide synthase (nNOS) as well as choline acetyltransferase (CHAT), and neuropathology of intestinal walls were examined in transplanted diabetic rats and compared with those in untreated diabetic rats and non-diabetic control animals.

Results: Mucosal villi in the intestine were thickened in diabetic rats and ADSC transplantation (Tx) nearly normalized the thickness of the mocosal wall. Neuronal distribution as demonstrated by PGP9.5 staining disclosed significant reduction of myenteric neuronal area and intramural axonal fibers in diabetic rats and these changes were improved by ADSC-Tx. Consistent with PGP9.5 staining, tissue contents of PGP9.5 were reduced in diabetic rats and corrected by Tx. Similarly, expressions of both PKB/Akt and pAkt were suppressed in the intestinal tissues of diabetic rats and corrected by Tx. There were also reduced mRNA expressions of fibroblast growth factor (FGF), vascular endothelial growth factor (VEGF), insulin-like growth factor (IGF)-I, nNOS and CHAT in the intestine of diabetic rats, and Tx all upregulated the expressions. There was no significant influence of Tx on the mRNA expressions of these factors in normal control rats. The microscopy of transplanted sites revealed increased microvessels and sparse infiltration of inflammatory cells in diabetic and normal control animals.

Conclusion: The results demonstrated that topical application of autologous ADSC into the gut wall improved diabetic enteropathy in rats, warranting the future clinical application of ADSC transplantation for hitherto untreatable condition of diabetic enteropathy.

1129

Oxidative stress damage at pain control serotoninergic and noradrenergic brainstem centres during diabetic neuropathy

C.S.C. Morgado[1,2], P. Pereira-Terra[1,2], M. Martins-Oliveira[1,2], F. Neto[1,2], I. Tavares[1,2];
[1]Institute of Histology and Embryology, Faculty of Medicine of Oporto, [2]IBMC, Porto, Portugal.

Background and aim: Painful diabetic neuropathy was recently shown to be due to central mechanisms, both in humans and animals. Loss of serotoninergic and noradrenergic neurons at brainstem pain control centres was shown to occur in streptozotocin-diabetic rats (STZ-rats). This impairment in descending modulation may account for spinal hyperactivity and exacerbated pain behavioural responses. Oxidative stress is common in diabetes, affecting peripheral sensory system and central areas involved in cognition and memory. Here, we evaluated the occurrence of oxidative stress damage at serotoninergic and noradrenergic brainstem areas directly involved in descending pain modulation.

Materials and methods: Male Wistar rats were injected with streptozotocin (60 mg/kg) or saline and were sacrificed at 10 weeks post-injection. Brainstem sections were immunoreacted for thryptophan hydroxylase (TpH) and tyrosine hydroxylase (TH) to detect serotoninergic and noradrenergic neurons, respectively; and for 8-hydroxy-2'-deoxuguanosine (8-OH-dG), the marker of oxidative DNA damage. Rostroventrolateral medulla (RVM) was analysed for TpH immunoreactivity. The A5, A6 and A7 noradrenergic cell groups were studied for TH expression. Another set of sections was analysed for 8-OH-dG expression in the above mentioned serotoninergic and noradrenergic areas. Data were compared by independent sample *t* test and presented as mean±SEM.

Results: STZ-rats presented marked hyperglycaemia and behavioural signs of painful diabetic neuropathy (mechanical hyperalgesia and tactile allodynia evaluated by the Randall-Selitto and von Frey tests, respectively). Significantly lower numbers of TpH labelled neurons were detected at RVM of STZ-rats (STZ: 4.9±1.71; Saline: 15.8±4.17). Regarding the noradrenergic cell groups, significant low numbers of TH immunoreactive neurons were detected at the A5 (STZ: 9.8±0.73; Saline: 13.9±1.34) with a tendency for reduction in A7 cell group (STZ: 15.6±3.49; Saline: 21.6±2.17). No difference was detected at the A6 noradrenergic cell group. Oxidative stress damage was significantly higher in RVM (STZ: 11.2±2.60; Saline: 1.6±0.80), A5 (STZ: 18.0±5.22; Saline: 4.9±1.49) and A7 (STZ: 10.1±2.49; Saline: 2.3±0.59) noradrenergic cell groups in STZ-rats. In the A6 noradrenergic cell group, oxidative damage was similar in both groups.

Conclusion: The association between decreases in the numbers of serotoninergic and noradrenergic neurons and oxidative stress damage suggests that this may be a leading mechanism in the impairment of inhibitory descending pain modulation in STZ rats. It is likely that a reversal of oxidative stress damage at the brainstem should prevent the observed neuronal losses. This study shows the importance of increasing the intake of antioxidants in diabetic patients in order to control neuronal dysfunction and pain during diabetic neuropathy.

Role for endoplasmic reticulum stress in prediabetic and diabetic neuropathy
I.G. Obrosova, P. Watcho, Y. Maksimchyk, H. Shevalye, R. Stavniichuk, S. Lupachyk;
Mechanisms of Diabetes Complications, Pennington Biomedical Research Center, Baton Rouge, USA.

Background and aims: Endoplasmic reticulum (ER) stress caused by accumulation of unfolded proteins in the ER lumen, contributes to beta-cell loss, insulin resistance, and plays an important role in the pathogenesis of both Type 1 and Type 2 diabetes. Taking into consideration that ER stress is associated with impaired cell signaling and oxidative damage, we evaluated the role of this phenomenon in the pathogenesis of prediabetic and diabetic peripheral neuropathies.
Materials and methods: The experiments have been performed in 1) Zucker lean and Zucker *fa/fa* rats, a model of obesity and Type 2 prediabetes, and 2) control and streptozotocin (STZ)-diabetic rats, a model of Type 1 diabetes. Peripheral neuropathy endpoints included sciatic motor nerve conduction velocity (MNCV), hind-limb digital sensory nerve conduction velocity (SNCV), thermal algesia (paw withdrawal latency), tactile allodynia (tactile response thresholds), and intraepidermal nerve fiber density (fluorescent immunohistochemistry). ER was evaluated by expression of BiP/GRP78 and GRP94 in the sciatic nerve (Western blot analysis).
Results: Both 16-wk-old Zucker *fa/fa* rats and STZ-diabetic rats with 12-wk duration of diabetes displayed ER stress response manifest by overexpression of BiP/GRP78 and GRP94 in the peripheral nerve. They also had nerve conduction velocity slowing and small sensory nerve fiber dysfunction. STZ-diabetic rats displayed reduced intraepidermal nerve fiber density. Treatment with the chemical chaperone trimethylamine N-oxide (TMAO), 1 mmol $kg^{-1}d^{-1}$ in the drinking water, for 4 wks, reversed SNCV deficit and alleviated thermal hypoalgesia and tactile allodynia in Zucker *fa/fa* rats. The same treatment also prevented SNCV deficit and partially prevented MNCV deficit and small sensory nerve fiber dysfunction and degeneration in STZ-diabetic rats. In both studies, TMAO did not affect blood glucose concentrations.
Conclusion: ER stress is implicated in the pathogenesis of prediabetic and diabetic peripheral neuropathies. Studies of biochemical mechanisms of ER stress-induced peripheral nerve damage are in progress.

PS 110 Autonomic neuropathy - clinical observations

1131

The reproducibility of cardiovascular reflex tests is not influenced by actual glucose values in young type 1 diabetic patients
T.T. Várkonyi[1], V. Szidor[1], A. Szász[1], R. Laurentzi[1], É. Börcsök[1], C. Lengyel[1], T. Nyári[2], P. Kempler[3], T. Wittmann[1];
[1]1st Department of Medicine, University of Szeged, [2]Department of Medical Informatics, University of Szeged, [3]1st Department of Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: The reproducibility of cardiovascular reflex tests (CRT) is well-documented, but the possible role of the current glucose levels on the heart rate and blood pressure responses in diabetic patients is unknown. The aim of our study was to analyse the CRT-s as well as continuously measured glucose values during the tests on three consecutive days in young patients with short-standing type 1 diabetes (DM).
Materials and methods: 10 young type 1 DM patients were included into the study (duration of DM: 8.2±6.7 yrs, age: 23.3±0.7 yrs, HbA1c: 8.8±0.6%; mean±SE). The five conventional Ewing CRT-s were performed on three consecutive days. During the tests the current glucose values were detected by continuous subcutaneous glucose measuring system (CGMS; Medtronic Ltd). One-way ANOVA test was applied for the statistical evaluation.
Results: The CRT results did not differ significantly between the days (mean values of the days: Valsalva ratio: 1.57-1.54-1.67; heart rate response to deep breathing: 26.4-22-25.7 beats/min; 30/15 ratio: 0.96-0.99-0.96; diastolic blood pressure response to handgrip: 24.8-19.8-23.9 mm Hg; orthostatic systolic blood pressure response: 7.7-8.9-6.3 mm Hg; AN scores: 2.7-2.4-2.5, $p>0.05$ for all tests). The subcutaneous current glucose levels did not show any statistical association with the daily results of the CRT-s. The fluctuation of glucose was not significant during the three days (mean glucose levels of the days: 7.2-9.6-5.7 mmol/l; $p>0.05$).
Conclusion: Our results confirm the high reproducibility of the cardiovascular reflexes in young type 1 diabetic patients. Data suggest that the short-term variability of cardiovascular responses is not influenced by the actual glucose levels. Our observations might indirectly support the importance of long-term glycemic exposure on the cardiovascular autonomic function in type 1 diabetes.

1132

Gastric neurostimulation significantly relieves symptoms of severe diabetic gastroparesis and reduces frequency of hospital contacts
P. Rask[1], P.F. Jensen[1], N. Ejskjaer[2];
[1]Department of Surgery, [2]Department of Endocrinology MEA, Aarhus University Hospital, Aarhus, Denmark.

Background: In its most unremitting form diabetic gastroparesis may present with continous nausea and vomiting leading to hospitalisation for fluid substitution and blood glucose control. Fortunately the condition is often more limited, although frequently resistant to standard pharmacological and symptomatic treatment.It is, however, commonly accepted that diabetic gastroparesis, symptomatic or asymptomatic, may severely impact blood glucose control and hamper the eficiency of pharmacotherapy.
Method: Selected Type 1 diabetes patients suffering severe symptoms of diabetic gastroparesis underwent extensive clinical examination to exclude other causes of dyspepsia. All were before and after implantation of a high-frequency low-intensity gastric neurostimulator subjected to detailed clinical studies including scintigraphic gastric emptying studies, cardiac autonomic function tests, gastroscopies, visceral-biomechanical studies, 24h-antroduodenal motility testing and qualitative symptomatic testing using a validated questionnaire. Patients: Fifteen patients, 7 male and 8 female, all Type 1 diabetes, all long duration of diabetes, all presenting with an array of late diabetic complications and attending the out-patient clinic at Department of Endocrinology MEA, Aarhus University Hospital. All had suffered symptoms of diabetic gastroparesis for several years resistant to standard treatment measures and all attempts of pharmacotherapy. All were frequently admitted to hospital for this condition. A proportion of the patients had been considered to be candidates for irreversible gastrointestinal surgery.
Results: Fifteen patients have been relieved to varying degrees of their symptoms of diabetic gastroparesis. Two male patients and three female patients

are completely relieved of nausea and vomiting. Several patients demonstrate halving of admission frequency and are predominantly admitted for treatment of competing diabetic late complications. Some have not been admitted to hospital after implantation of the gastric neurostimulator, whereas they were frequently so before. Some have returned to full-time work. We were not able to demonstrate improvements in glycaemic control in this small cohorte.
Conclusion: We conclude that the patients selected and included in our study were significantly relieved of severe symptoms of diabetic gastroparesis and the frequency of hospital contacts overall were reduced.

The association between diabetic autonomic neuropathy and microalbuminuria
E.S. Kim, S. Beom, S.A. Kim, W. Shim, E.H. Lee, J. Yoo, J. Nam, M. Cho, J.S. Park, C. Ahn, B. Cha, E.J. Lee, S. Lim, K.R. Kim, H.C. Lee;
Division of Endocrinology, Department for Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and aims: Diabetic autonomic neuropathy (DAN) has a negative impact on quality of life and survival in patients with type 2 diabetes (T2DM). However, as most of affected patients remain asymptomatic for a long period, it is frequently overlooked. As microvascular diseases share pathogenesis mainly originated from chronic hyperglycemia, microalbumiuria which is annually measured in patients with T2DM might be associated with DAN. We performed this study to investigate whether urinary albumin excretion (UAE) could predict diabetic autonomic neuropathy (DAN).
Materials and methods: We retrospectively reviewed records of patients with type 2 diabetes (n=953) who had received annual diabetes-related complication screening between January 2007 and June 2009. Tests for autonomic functions (AFT) measured heart rate variability during breathing, Valsalva maneuver, 30:15 ratio, blood pressure (BP) response to standing and handgrip. The results of each test were scored as 0 for normal and 1 for abnormal and assessed total score considering positive DAN larger than 2. Urinary albumin excretion (UAE) was calculated in spot urine estimating ratio of urinary albumin (mg) dividing urinary creatinine (g).
Results: The prevalence of DAN was 42.1% (n=401). Subjects with DAN had less prevalent of male and significantly higher age, longer diabetes duration and increased CAVI and IMT. On the contrary there was no difference in glycemic control status (FBS, HbA1C), hypertension, lipid profiles. Urinary albumin excretion was linearly increased according to AFT score [0 (n=176), 1 (n=221), 2 (n=194), 3 (n=79), 4 (n=31), 5 (n=3); UAE 36.1 ± 66.5, 49.7 ± 113.8, 68.3 ± 138.8, 89.9 ± 149.7, 89.8 ± 149.6, 146.1 ±224.2, 403.1 ± 386.0 mg/g, *P* for trend <0.001]. In the multivariate logistic analysis, UAE was significantly associated with DAN [odds ratio (OR) 1.002; 95% confidence interval (CI) 1.001-1003, besides age, female sex, duration, smoking status, previous CAD.
Conclusion: Elevated urinary albumin excretion was significantly associated with AFT score and a predictor for DAN in patient with T2DM. This result suggests that annual exam of UAE could additionally give information to discriminate high risk patients in DAN in addition of diabetic nephropathy.

1134

Effect of adjuvant influenza vaccine on systemic inflammation and cardiac autonomic function in patients with type 2 diabetes
G.A. Lanza[1], D. Pitocco[2], F. Zaccardi[2], L. Barone[1], F. Crea[1], G. Ghirlanda[2];
[1]Cardiology, [2]Internal Medicine, Catholic University, Rome, Italy.

Background and aims: Both inflammation and impaired cardiac autonomic function are known to increase the risk of coronary events. Recent data points out a pathogenetic link between nervous autonomic system (ANS) and inflammation, but the exact terms of this relation in the clinical are still poorly defined. In this study we assessed the effect on cardiac autonomic function of the administration of an inflammatory stimulus, represented by influenza A vaccine. The effect on platelet reactivity was also assessed to better define the cardiovascular risk profile consequent to the inflammatory stimulus.
Materials and methods: A 24-hour electrocardiogram Holter recording was performed both at baseline and after 24 hours from adjuvant influenza A vaccine in 30 patients with type II diabetes mellitus (age 62±8 years, 19 men). C-reactive protein (CRP) and interleukin-6 serum levels were measured, and monocytes platelets aggregates (MPA) were assessed before and 48 hours after vaccination.
Results: Following vaccination, inflammatory cytokines, MPAs and monocyte-platelet receptor expression increased (e.g., CRP: 2.6±2.8 vs. 7.1±5.7 mg/L; p<0.0001), whereas HRV decreased (e.g., very low frequency [VLF] amplitude: 34.6±11.8 vs. 31.0±10.2 ms; p=0.002). The changes in CRP correlated with those of most HRV variables, but greater CRP increases were associated with lower HRV reductions; the most significant correlation was between changes in CRP and in SDNN(r=0.43; p=0.02) and VLF amplitude (r=0.39; p=0.03). MPA changes did not correlate with changes in CRP levels or in HRV variables.
Conclusion: In this study we show that exposition to an attenuated infectious stimulus induces, together with the expected inflammatory reaction, a relative increase of adrenergic tone in the sympatho-vagal balance of cardiac autonomic function. However, enhanced inflammatory reaction seemed to cause a vagal activation which limited the impairment of HRV and was likely finalized to antagonize the inflammatory related tissue damage. Influenza vaccination in our type 2 diabetic patients also induced increased monocyte and platelet activation that might transiently increase the risk of acute cardiovascular events after the treatment.

1135

Erectile dysfunction, androgen deficiency and chronic complications in male diabetic patients
O. Georgescu, M. Ursache, C. Barbu, S. Fica;
Endocrinology, Diabetes and Nutrition, Elias Emergency Hospital, Bucharest, Romania.

Background and aims: Erectile disfunction (ED) can be present in male diabetic patients not only induced by androgen deficiency, but also as a consequence of chronic complications.
The aim of our study was to evaluate the corelation between ED, sex-hormonal status and chronic complications in patients with diabetes mellitus (DM).
Materials and methods: 292 patients (44 T1DM/ 248 T2DM) aged between 20-75 years (mean 52.06±3.7 years) were evaluated by sex-hormonal status (DHEA , free testosterone) and by presence of chronic micro- and macrovascular angiopathy. ED was diagnosed by a score under 22 of the 5-item IIEF questionnaire. All patients with free-testosterone under 70 pg/ml were considered hypogonadic.
Results: The prevalence of ED was 84.24% in whole study group (higher in T2DM 87.5%, than in T1DM 65.9%). In patients with ED the prevalence of hypogonadism was 31.57% in T1DM and 26.73% in T2DM. From hypogonadic T2DM subjects 93.9% have ED, while in hypogonadic T1DM only 66.6% have ED (p=0.04). In older man with T2DM (over 60 years) IIEF-score was significant corelated with DHEA value r=0.57, p=0.008. We did not found any corelation between ED and macrovascular diseases. There was a significant corelation between ED and retinopathy(r=0.37, p=0.003) in T1DM and also with neuropathy (r=0.42, p=0.04) in T2DM.
Conclusion: ED is frequent in diabetic patients more associated with microvascular complications. Hypogonadic status can explain 30% of ED. In older diabetic men the severity of ED is related to low DHEA-value.

1136

Erectile dysfunction in diabetics and non-diabetics due to macrovascular lesions
A.Z. Akbarov, G.N. Rakhimova;
Diabetology, Centre for the Scientific and Clinical Study of Endocrinology, Tashkent, Uzbekistan.

Background and aims: To study incidence of erectile dysfunction (ED) in the diabetics and non-diabetics by macrovascular lesions.
Materials and methods: We examined 601 male patients with type 1 and type 2 diabetes mellitus and 413 non-diabetic persons aged from 20 to 70 in both groups. The examinees were differentiated by presence of ischaemic heart disease (IHD), myocardial infarction, cerebral circulation disturbance and stroke as per medical history, clinical-laboratory investigations and instrumental data. They were inquired with the International Erectile Function Index questionnaire.
Results: ED incidence in the diabetics with IHD (85.4+2.65%) was 18.7% higher (P<0.001) than in the diabetics without macrovascular lesions (66.7+2.5%). Similar tendency in ED incidence was observed in the non-diabetics, thus in persons with IHD but without DM the incidence (79.2+8.29%) was 45.3% higher (P<0.001) than in the non-diabetics and macrovascular

lesions (33.9+2.44%). Comparison of ED incidence in groups of the non-diabetics without macrovascular lesions with ED incidence in the group of the diabetics without macrovascular lesions (66.7+2.5%) showed that it was 32.8% higher (P<0.001) than in the non-diabetics without macrovascular lesions (33.9+2.44%). ED incidence in the diabetics with myocardial infarction (85.0+5.6%) was 18.3% higher (P<0.001) than in the diabetics without macrovascular lesions (66.7+2.5%). Similar tendency was observed in the non-diabetics with and without myocardial infarction. Thus, in 3 of 3 non-diabetics with IHD (100+0%) ED of moderate severity was found in one person, the most severe one being registered in two, while in the non-diabetics without IHD the parameter was 33.9+2.44% (P<0.001). ED incidence in the diabetics with cerebral circulation disturbances was 83.3+7.6%. It is 16.6% lower than the parameter in the non-diabetics. The highest ED incidence could be seen in the diabetics after the stroke (100%). In the group of the non-diabetics without macrovascular lesions the stroke was registered in one patient with ED of intermediate severity.As a whole in both diabetics and non-diabetics with macrovascular lesions higher ED incidence can be observed than in patients without the lesions. Thus, in the diabetics and non-diabetics without the lesions ED incidence was 66.7+2.5% and 33.9+2.44% respectively. At the same time in the diabetics and non-diabetics with the macrovascular lesions ED incidence was found 85.9+2.1% and 84.2+5.9%, respectively.
Conclusion: Thus, in patients with macrovascular lesions (IHD, myocardial infarction, cerebral circulation disturbance and stroke) regardless of DM presence ED incidence is higher than in persons without the lesions in question.

1137

Sexual dysfunction in pre-menopausal normal and diabetic women; clinical, psychologic, cardiovascular, and neurophysiological correlates
A.E. Pontiroli[1,2], D. Cortelazzi[1], C. Mauri[1], A. Marconi[1], M. Guazzi[1], M. Cristina[2], B. Zecchini[2], C. Cattalini[2], A. Innocenti[1], G. Bosco[1];
[1]Dipartimento di Medicina, Chirurgia e Odontoiatria, Università degli studi di Milano, [2]Ospedale San Paolo, Milano, Italy.

Background and aims: Female Sexual Dysfunction (FSD) is frequent in women with diabetes mellitus or metabolic syndrome. Aim of this study was to analyze clinical, cardiovascular, and neurophysiological correlates of FSD.
Materials and methods: We evaluated 66 pre-menopausal women, 42 healthy and 24 with diabetes (8 T1DM, 16 T2DM, duration 9.6±1.91 y, with no clinical micro-, macro-angiopathic, or neurologic complications), through administration of Female Sexual Function Index questionnaire (FSFI). In all women we studied: physical activity, smoking habits, parity, weight, BMI, waist circumference (WC), Beck Depression Inventory (BDI), Diabetic Somatic Neuropathy Score (DSN), endothelial-mediated blood flow, ECG (for heart rate and Qtc, indexes of sympathetic activity), intima-media thickness (IMT), insulin, fasting glucose, HOMA-IR index, fibrinogen, cholesterol (total, HDL-, LDL-), triglycerides, HbA1c, HS-PCR, electromyography (amplitude and conduction of peroneal, posterior tibial, and sural nerves).
Results: Diabetic women differed from healthy women for BDI, fasting glucose, triglycerides, HbA1c, nerve conduction (p<0.05 to p<0.001), and at FSFI for orgasm (p<0.05). In healthy and diabetic women considered together, FSFI score was directly correlated with physical activity (r = .266), and with peroneal nerve amplitude (r = .289), and inversely with parity (r = .298), BDI (r = .483), SDN (r = .439), IMT (r = .329), (p<0.05 to p<0.01).
Conclusion: These data indicate that: 1) FSFI is reduced in reasonably healthy diabetic women even in the absence of complications; 2) FSFI correlates with psychologic, neurophysiologic, and cardiovascular parameters. Longer observation periods are required to evaluate FSFI as a possible risk factor for cardiovascular events.

PS 111 Autonomic neuropathy - blood pressure and heart

1138

Heart rate variability during the night is related to hyperglycaemia in patients with type 2 diabetes
K. Makrilakis[1], S. Liatis[1], P. Thomakos[1], S. Kalopita[1], I. Vlahodimitris[2], N. Katsilambros[1];
[1]First Department of Propaedeutic Medicine, Athens University Medical School, [2]Department of Cardiology, Laiko General Hospital, Athens, Greece.

Background and aims: Heart rate variability (HRV) represents a non-invasive technique that allows a detailed study of the cardiac autonomic nervous system, by assessing the spontaneous fluctuations of heart rate. HRV is reduced in patients with diabetes and is considered a risk factor for cardiovascular mortality. Aim of the present study was to assess the relationship between glycaemia (measured by continuous glucose monitoring subcutaneously [CGMS]) and HRV (measured by continuous ECG monitoring) simultaneously in patients with Type 2 diabetes (T2D).
Materials and methods: A total of 31 (20 males) T2D patients (mean age [±SD] 56.2±9.9 years, diabetes duration 5.5±4.2 years), treated with oral antidiabetic agents, underwent ECG recording and CGMS, simultaneously and continuously, for 48 hours. HRV was calculated by frequency and time domain analysis. A separate analysis was performed regarding HRV during the day and night period (11.00 pm to 08.00 am). CGMS was performed by a needle electrode placed subcutaneously in the abdomen, acquiring data every 5 min (288 measurements/day), with a microdialysis system.
Results: There was no correlation between HRV and HbA1c or 48-h mean plasma glucose. Weak negative correlations were found between HRV indices and hyperglycemia, expressed as the area under the curve (AUC) of glucose values above 180 mg/dl (AUC_{G180}). Strong negative correlations were observed, however, between HRV indices during the night period and 48-h AUC_{G180}. No such correlations were observed during the day time (Table). HRV, in both frequency and time domain analysis, was significantly higher during the night period than during the day (P values for all indices < 0.001).
Conclusion: HRV during the night period is negatively correlated with 48-h hyperglycemia, while no such association is observed during the day. It may be hypothesized that this finding reflects a relation between HRV and hyperglycemia, being unmasked during sleep, when HRV is not affected by day-time activities.

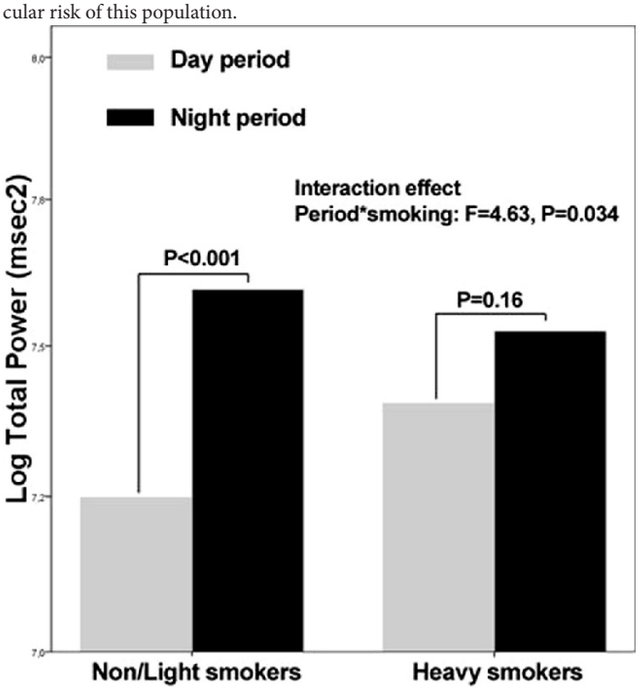
Linear regression of indices of HRV during night and AUCG180 (adjusted for duration of diabetes)

Indices of HRV	β-coefficient	β-coefficient	P	P
A. Time domain analysis	**Day**	**Night**	**Day**	**Night**
Percent of differences between normal-to-normal RR intervals >30 ms (PNN-30)	-0.19	**-0.40**	0.30	**0.03**
Percent of differences between normal-to-normal RR intervals >50 ms (PNN-50)	0.03	**-0.48**	0.97	**<0.01**
Root mean square of successive normal-to-normal RR interval difference in ms (RMSSD)	-0.05	-0.36	0.80	0.052
B. Frequency domain analysis				
Total power of HRV (TP)	-0.1	**-0.38**	0.87	**0.03**
High-frequency domain of HRV (HF)	-0.25	-0.38	0.18	0.051
Low-frequency domain of HRV (LF)	0.10	-0.20	0.61	0.29

1139

Heavy smoking blunts the circadian rhythm of heart rate variability in patients with type 2 diabetes
S. Liatis[1], K. Makrilakis[1], P. Thomakos[1], S. Kalopita[1], I. Vlahodimitris[2], N. Katsilambros[1];
[1]First Department of Propaedeutic Medicine, Athens University Medical School, [2]Department of Cardiology, Laiko General Hospital, Athens, Greece.
.
Background and aims: Autonomic nervous system control of the cardiovascular system has a distinct circadian rhythm and this may be an important mechanism underlying the diurnal distribution of cardiac events. Heart rate variability (HRV) represents a non-invasive technique that allows a detailed

study of the cardiac autonomic nervous system, by assessing the spontaneous fluctuations of heart rate. HRV is reduced in patients with T2D, while it is known that smoking also decreases HRV. Aim of the present study was to assess the effect of smoking on circadian rhythm of HRV in patients with Type 2 diabetes (T2D).
Materials and methods: Sixty three consecutive non-smokers and 35 consecutive smokers, attending the diabetes outpatient clinic of a University Hospital, treated with oral antidiabetic agents, underwent continuous ECG monitoring for 24 hours. HRV was calculated by frequency and time domain analysis. A separate analysis was performed regarding HRV during the day and night period. Smokers were further divided into heavy smokers (n=29), defined as being exposed to ≥10 pack-years (py), and light smokers, being exposed to <10 py.
Results: Smokers were younger (mean age: 54.4±9.6, vs. 61.5±8.8 years, P<0.01) and had a shorter duration of diabetes (median duration: 4 vs. 7 years: P=0.054). Smokers had higher HRV indices than non-smokers, although statistical significance was attained only for high and low-frequency domain analysis during the day. Both smokers and non-smokers had higher HRV during the night (all P values <0.05). Heavy smokers, however, showed a statistically significant increase in HRV during the night period only for some domains of HRV analysis (high-frequency domain (HF), low frequency domain (LF) and percentage of differences between normal-to-normal RR intervals >30 ms [PNN-30]). In one-way repeated-measures ANOVA, heavy smoking was associated with a blunted increase of HRV during the night (Figure). This finding was consistent for all indices of HRV, both in frequency and time domain analysis.
Conclusion: Smoking >10 pack-years blunts the circadian rhythm of HRV in patients with T2D. This effect may be implicated in the increased cardiovascular risk of this population.



1140

Autonomic neuropathy as the cause of the QTc dispersion in diabetes type 2
J. Tatoń[1], M. Bernas[1], Z. Szczeklik-Kumala[1], M. Chmielewski[2];
[1]Department of Internal Diseases and Diabetology, [2]Department of Cardiology, Medical University of Warsaw, Poland.

Background and aims: The increase of the QT_c dispersion reflects the electrical instability of the diabetic heart. It is an important risk factor of sudden death caused by ventricular fibrillation. It occurs in persons with diabetes mellitus more frequently than in the general population. A closer determination of the pathogenetic factors involved in QT_c dispersion should improve the preventive measures.
Materials and methods: For the study, a) a general cohort of 185 males with diabetes mellitus type 2 without symptoms of ischemic heart disease, aged 57.6±7.1 years, and b) 52 persons without diabetes mellitus and without symptoms of ischemic heart disease - males, aged 58.8±7.2 years - were qualified. The following investigations were conducted on those under study: standard clinical examination, indices of metabolic compensation of diabetes mellitus (daily glycaemia profiles, HbA_{1c}, lipid profile), serum potassium, natrium calcium and magnesium levels, resting ECG, exercise test according to Bruce protocol and the battery of tests for the autonomic innervation of the heart according to Clarke protocol. The subgroup of diabetes mellitus type 2 with a diagnosis of autonomic neuropathy was composed of 84 subjects, males aged 56.8±6.5 years. The QT length was derived from the average of readings from a 12-leads ECG and calculated with the Bazett's formula: $QT_{cd} = QT_{c\,max} - QT_{c\,min}$.
Results: In diabetes mellitus type 2 under study, without clinical symptoms of ischemic heart disease, the statistically significant (p<0.001) increase of QT_c - to 41±21 ms - in comparison with the QT_c in the control group, 22±11 ms - was revealed. In the subgroup of diabetes mellitus type 2 with the silent ischemia of the heart, the QT_c values were similar to those in the subgroup of diabetes mellitus type 2 without such ischemia. This was in contrast to the finding of a correlation between the presence of autonomic neuropathy and the increase of the QT_c dispersion.
Conclusion: In persons with diabetes mellitus type 2 without clinical symptoms of heart ischemia the disturbances of the ventricular repolarization as manifested by an increase of the dispersion of QT_c, are correlated with the markers of autonomic neuropathy. Such correlation was not found in the subgroup without symptoms of heart ischemia or with the asymptomatic ischemia of the heart without autonomic neuropathy. Therefore, in cardiological care for diabetic persons, early testing for autonomic neuropathy should be included as a matter of routine.

Diabetes mellitus type 2 no clinical heart ischemia no silent heart ischemia	Diabetes mellitus type 2 silent heart ischemia present
24±11 ms	23±14 ms (p>0.05)
Diabetes mellitus type 2 no clinical symptoms of heart ischemia autonomic neuropathy present	Diabetes mellitus type 2 no clinical symptoms of heart ischemia autonomic neuropathy absent
53±18 ms	38±2 ms (p<0.05)

1141

The prognostic value of sudomotor function for the development of cardiovascular disease and retinopathy: a 3-year follow up of diabetic patients
D.S. Tesic[1], V. Popovic[2], M. Mitrovic[1], J. Novakovic-Paro[1], B. Vukovic[1];
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Institut for Internal Diseases, [2]Clinic of Vascular Surgery, Institut for Surgical Diseases, Novi Sad, Serbia.

Background and aims: The aim of the present study was to evaluate the risk for vascular morbidity or death and retinopathy in relation to an abnormal response to a commercially available test of distal autonomic function (Neuropad®).
Materials and methods: To that end, we performed a 3-year follow- study of type 2 diabetic patients attending the outpatient clinic. A total of 348 adult patients were evaluated for the degree of retinopathy and levels of HbA1c, blood pressure, serume creatinine and proteinuria. Somatic sensory neuropathy was documented using the Neuropathy Disability Score, and autonomic neuropathy (sudomotor neuropathy) was determined on the sole of the foot using the Neuropad® response including time to colour change. Patients were divided into two groups: those without and with new vascular morbidity and causes of death which were registered by one and the most severe event only.
Results: Initially there were 348 patients with type 2 (159 male, mean age 62.0±8.8y; mean disease duration 14.8±8.6y). NDS was >5 (abnormal) in 83 (23.9%) and no change in Neuropad colour by 10 minutes was observed in 103 (29.6%). Significant direct correlations were observed between an abnormal Neuropad test and age (r_s=0.31, p<0.001), waist circumference (r_s=0.17, p=0.003), BMI (r_s=0.25, p<0.001); significant negative correlations were observed with height (r_s=-0.17, p<0.001) and serum HDL cholesterol (r_s=-0.13, p=0.003).The data represent values taken 3±1years (mean±SD) after initial evaluation. Twenty-two patients developed atherosclerotic vascular disease, i.e. myocardial infarction (n=9), cerebrovascular disease (n=9), or amputation (n=4), and 19 died. The observed annual mortality rate was 18.4/1000 compared to an expected rate of 12.6/1000 for the general population with corre-

sponding age and sex. Male gender (62.8% vs. 45.6%, p=0.04), age (68.8±6.1y vs. 61±8.1y, p<0.001), high BMI (30.3±4.9 vs. 27.1±2.3, p<0.01), high triglycerides (3.1±0.9 vs. 2.0±0.7mmol/l, p<0.01), low HDL cholesterol (1.06±0.3 vs. 1.16±0.17mmol/l, p<0.01) and time to complete Neuropad colour change (22.6±5.8mins vs. 9.1±6.7mins, p<0.01) were associated with vascular disease or death. Time until total colour change was found to be a prognostic marker for the development of vascular disease and death in patients treated with insulin at baseline (23.3±5.9mins vs. 8.7±4.7mins, p<0.01), whereas this was not the case in patients treated with oral agents at baseline (11.3±4.5mins vs. 7.4±5.6mins, NS). However, insulin treatment per se was not associated with an icreased mortality or morbidity. Time until total colour change was correlated with incidence of prolipherative retinopathy regardless of diabetes treatment (17.3±6.9mins vs. 9.1± 5.4mins, p<0.01).
Conclusion: This study showed that abnormal test of sudomotor function was a prognostic factor for vascular morbidity and death in type 2 diabetic patients treated with insulin but not in patients treated with oral agents.

1142

99mTc - Myoview gated - SPET and heart rate variability measurement in detection of early cardiovascular changes in diabetic patients
M. Mokan[1], M. Migra[1], M. Kutlák[1], A. Lacko[2], P. Galajda[1];
[1]1. Internal Clinic, Faculty Hospital in Martin, Slovakia, [2]Internal Clinic, Central Military Hospital, Ružomberok, Slovakia.

Background and aims: Chronic metabolic alteration in diabetic disease implicates the changes in myocardial perfusion and autonomic nervous system. Risk of myocardial infarction is 3 times higher compared to whole population. We decided to examine diabetic patients without history of cardiovascular disease for presence of cardiac autonomic cardiomyopathy and compare the results from standard examinating methods (treadmill test and echocardiography) to 99mTc - Myoview gated - SPET findings.
Materials and methods: We examined 47 patients, 20 individuals with T1DM (13 men, 7 women), average age 37 ± 12,7 years and 27 individuals with T2DM (14 women, 13 men), average age 60 ± 9,2 years. Written consent was obtained from all patients prior the study. In all patients we provided echocardiography and battery of Ewing´s testing combined with heart rate variability (HRV) examination. Thereafter patients underwent treadmill test and stress 99mTc - Myoview gated-SPET. Vascular and metabolic determinants were recorded. Colected data were analysed using nonparametric statistic methods.
Results: Treadmill test was negative in all patients. Echocardiography revealed diastolic dysfunction in 10 % of T1DM and 11 % of T2DM, no patient had systolic dysfunction. Scintigraphy confirmed hypoperfusion in 35 % T1DM (p = 0,01) and in 60 % T2DM (p = 0,001). Diagnose of cardiac autonomic neuropathy based on Ewing´s testing and examination of HRV was estimated in 60 % of T1DM patients (p = 0,001) and 77 % of T2DM patients (p = 0,001). In T1DM group we found association between cardiac autonomic neuropathy (CAN) and frequency of hypoglycaemia (p = 0,04) and trend with duration of diabetes mellitus (p = 0,069). We did not find any correlation among all examined parameters in paciwnts with T2DM.
Conclusion: We revealed high incidence of cardiovascular changes characterised with myocardial hypoperfusion and cardiac autonomic neuropathy among diabetic patients while treadmill test and echocardiography showed negative finding. Therefore we suggest that heart disease develops in diabetic patient many years undetected and advanced preventive arrangement is needed.

1143

The effect of cardiovascular autonomic neuropathy on progressing chronic heart failure in patients with type 2 diabetes mellitus
S.N. Botova, L.G. Strongin, I.G. Pochinka;
Nizhny Novgorod State Medical Academy, Russian Federation.

Background and aims: Chronic heart failure (CHF) in patients with diabetes mellitus (DM) is a frequent and with poor prognosis. Cardiovascular autonomic neuropathy (CAN) is a common complication of DM, associated with increased mortality and myocardial ischemia. Aim: to study the influence of CAN on progressing CHF in patients with Type 2 DM.
Materials and methods: Fifty - nine patients with CHF and Type 2 DM with CAN (Group A) and 29 patients with CHF and Type 2 DM without CAN (Group B) were enrolled in the study. Both groups were comparable in age, gender, BMI, stage of CHF, there were no patients with acute myocardial infarction (MI) or advanced diabetic nephropathy. The 6 minutes walking test, echocardiography, and evaluation of the heart rate variability (HRV) by 5 minutes ECG monitoring were performed. The study lasted for a year.
Results: Within a year the MI has developed in 10 patients of group A and 1 patient of group B (p = 0,049). The patients of group A, who have suffered MI during supervision, were characterized by especially low parameters of standard deviation of all NN-intervals (SDNN). In particular, of patients of group A with the level SDNN <20 ms 8 patients (32 % from all patients with level SDNN <20 ms) have suffered MI, on the contrary, in patients with parameter of SDNN within the limits of 20 - 33 ms MI has developed only in 2 (p = 0,016). In both groups severity of CHF has increased, but in group A progressing CHF was more expressed. It has been demonstrated by worsening of clinical features, decrease of the left ventricle function. The decrease of the ejection fraction of the left ventricle, in 1 year was significantly higher in group A compared to group B (Median [25th; 75th percentiles] 4 [3; 7] v 2 [2; 5]), p = 0,019). In a year a decrease according to 6 minutes walking test was significantly higher in group A than in group B (Median [25th; 75th percentiles] 50 [20; 80] v 15 [4; 45], p = 0,023).
Conclusion: The risk of myocardial infarction of the patients with combination of Type 2 diabetes mellitus and chronic heart failure was higher in the presence of cardiovascular autonomic neuropathy. The level of SDNN lower than 20 ms is the precursor of a negative cardiovascular prognosis. Cardiovascular autonomic neuropathy causes the progressing chronic heart failure in the patients with Type 2 diabetes mellitus.

1144

Autonomic function and circadian blood pressure changes in patient with impaired glucose tolerance
N. Nemeth[1], Z. Putz[1,2], Á.G. Tabák[1], I. Istenes[1], T. Martos[1], A. Körei[1], Z. Hermányi[1,2], K. Keresztes[1], G. Jermendy[2], P. Kempler[1];
[1]Ist Dept of Internal Medicine, Semmelweis University, [2]3rd Dept of Internal Medicine, Bajcsy Zsilinszky Hospital, Budapest, Hungary.

Background and aims: Diminished circadian blood pressure changes may be present in patients with diabetes mellitus, in partly related to autonomic neuropathy.
Materials and methods: The aim of our study was to evaluate whether or not a similar connection may exist in patients with impaired glucose tolerance (IGT). We examined 46 patients with IGT (age: 53.04±11.10 years, fasting blood glucose 5.40±0.57 mmol/l; 120 min blood glucose: 8.61±1.01 mmol/l; HbA_{1c}: 5.97±0.38 %; x±SD) while 45 healthy subjects (age: 55.84±11.41 years) served as controls. Cardiovascular autonomic neuropathy was detected by the five standard tests of cardiovascular function. Systolic and diastolic blood pressure (BP) means just as systolic and diastolic diurnal indices were assessed by 24-hour ambulatory blood pressure monitoring.
Results: Significant differences were found between IGT and control subjects regarding the following parameters: beat-to-beat variation (11.90±5.70 vs. 19.50±4.10 beats/min; p=0.0001), Valsalva ratio (1.23±0.25 vs. 1.46±0.22; p=0.0001) and increase of diastolic blood pressure during sustained handgrip (19.90±7.90 vs. 23.70±6.10 mmHg; p=0.012) were lower, while postural systolic blood pressure changes (4.37±5.70 vs. -0.60±2.00 mmHg; p=0.0001) were higher in patients with IGT versus control group. Both systolic (9.58±7.59 vs. 13.70±5.90; p=0.003) just as diastolic (15.50±10.71 vs. 18.93±7.13; p=0.095) diurnal indices were lower in IGT subjects compared to controls. The 24-hour systolic (121.80±5.49 vs. 116.75±9.85; p=0.048) and diastolic (74.95±3.86 vs. 71.61±6.10; p=0.008) blood pressure means were significant higher in IGT versus control group.
Conclusion: Our data suggest that the presence of cardiovascular autonomic neuropathy is associated with diminished circadian blood pressure changes in patients with impaired glucose tolerance.

1145

Influence of vagosympathetic changes on arterial stiffness in diabetic and obese patients
Q. Chen[1,2], H. Dabire[1,3], S. Chiheb[1], I. Banu[1], E. Cosson[1];
[1]Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, BONDY, France, [2]Shanghai Clinical Center for Endocrine and Metabolic diseases, Shanghai Institute of Endocrine and Metabolic Diseases, China, [3]INSERM U841, Maisons alfort, France.

Background and aims: Arterial stiffness is often increased in patients with diabetes or obesity. Several data suggest the role of vagosympathetic changes

in arterial hypertension. The aims of the present study were to examine the role of cardiovascular vagosympathetic changes on peripheral and central arterial stiffness in patients with type 2 diabetes or obesity.
Materials and methods: We included 207 patients (142 hypertensive) with type 2 diabetes (T2D) and 68 non diabetic obese (22 hypertensive) patients. Arterial stiffness was evaluated by measuring carotid to femoral pulse wave velocity (PWV) (Complior®) and by brachial and finger pulse pressure (PP), vagosympathetic activity by spectral analysis of heart rate (HR) and blood pressure (BP) variations (Finapres ; HF : high frequency and LF : low frequency peak).
Results: In T2D patients as compared with obese patients, PWV ($p < 0.01$), brachial ($p < 0.001$) and finger ($p < 0.05$) pulse pressure (PP) were significantly higher and HF-HR ($p < 0.05$) lower, and this was confirmed after age and blood pressure adjustment. In T2D patients, PWV correlated significantly with age, systolic BP, LF-systolic BP, microalbuminuria and duration of diabetes and negatively with creatinine clearance and HF-HR and was significantly higher in the patients with peripheral neuropathy or peripheral vascular disease ($p<0.05$ to <0.001) ; brachial and finger PP also correlated significantly with all these parameters. In obese patients PWV and similarly brachial and finger PP correlated with age, systolic BP, microalbuminuria and negatively with creatinine clearance and HF-HR ($p = <0.01$ to < 0.001). In multivariate analyses including these parameters as independent variables, PWV was significantly associated with age both in T2D and obese patients, and with systolic BP and BMI in T2D patients; brachial PP correlated with age in both groups; finger PP correlated with HF-HR, LF-systolic BP and age in T2D patients ($p<0.001$, 0.01 and 0.05) and with HF-HR and systolic BP in obese patients ($p <=0.01$for both).
Conclusion: These data strongly suggest that in T2D and non diabetic obese patients, vagosympathetic changes play a major role in stiffness of small but not large peripheral arteries.

PS 112 Diabetic foot - clinical observations

1146

Diabetes related amputation incidence in an inner city multiethnic population in the UK before and after the introduction of multidisciplinary diabetes foot care, 2000-2008

M. Rossi[1], P. Tzoulis[1], D. Brudney[1], J. Buchanan[1], J. Preece[1], A. Wilson[2];
[1]Department of Diabetes, [2]Department of Surgery, The Whittington Hospital NHS Trust, London, United Kingdom.

Background and aims: Previous studies have suggested that appropriate multidisciplinary diabetes care can reduce the incidence of lower extremity amputations. According to the U.K. National Centre for Health Development Data for 2003-04, our inner city area in London was reported to have a higher number of diabetic amputations than the national average and amongst the highest within London. The Combined Foot Clinic was established in 2005 to offer multidisciplinary diabetes care for patients with diabetes related foot ulcers. We introduced care pathways and protocols for managing diabetic foot ulcers and raised awareness of the diabetic foot among primary care healthcare professionals through an educational programme. The aim of this study was to assess changes in diabetes-related lower extremity amputations in a multiethnic population over an 8-year period following the introduction of a multidisciplinary foot team. We reviewed the diabetes care of patients with diabetic amputations prior to, during and after admission.
Materials and methods: Our hospital covers a multiethnic population in an inner city area of London. All diabetes related lower extremity amputations in our insitution between 2000 and 2008 were identified via coding. Data were collected retrospectively and were analysed for the period before (2000 - 2005) and after (2006 - 2008) the introduction of the multidisciplinary foot team.
Results: From 2000 to 2005, 104 amputations in 64 patients (mean age 68.6 years, 70% males and 30% females, mean duration of diabetes 15 years) were identified with an incidence of 17.3 amputations/year. There were 38 major amputations (6.3/year) and 66 minor (11/year). Perioperative mortality was 6.6 %. From 2006 to 2008, 44 amputations in 33 patients (mean age 70.1 years, 72% males and 28% females, mean duration of diabetes 15 years) were identified with an incidence of 14.7 amputations/year. There were 9 major amputations (3/year) and 35 minor (11.7/year). Perioperative mortality was 4.6 %. During admission, between 2006 and 2008, 75 % of patients had HbA1c (median HbA1c 7.3%) compared with 41% between 2000 and 2005 (median HbA1c 7.9%). During admission, 81% of the patients were reviewed by Podiatry/Tissue Viability team compared with 40% for the previous period. After discharge, the proportion of patients who had follow-up by the Diabetes team increased from 62% to 73% and by Podiatrist from 43% to 80%. Overall, considerable improvement in the involvement of diabetes team and podiatry services was reported. Improvement in foot care services after 2005 led to a 53 % reduction in the incidence of major diabetes related amputations from 6.3/year to 3/year and a 15 % reduction in total diabetic amputations in our population from 17.3/year to 14.7/year. Overall, the incidence of major diabetes related amputations in our area has decreased to 1.2/100,000 general population/year and of total amputations to 5.8/100,000 population/year and is much lower than the national incidence of 3.4/100,000/year and 8.7/100,000/year respectively. Our perioperative (1-month) mortality rate is 4.6 % compared to 6.6 % nationally.
Conclusion: We demonstrated considerable improvements in outcomes of diabetes related amputations following improvements in foot care through multidisciplinary team work.

1147

Changes in the incidence of lower extremity amputations in people with and without diabetes in England between 2004 and 2008

E.P. Vamos, A. Bottle, A. Majeed, C. Millett;
Department of Primary Care & Public Health, Imperial College London, United Kingdom.

Background and aims: During the last decade, there was a consistent upward trend in the number of non-traumatic lower extremity amputations in people with diabetes in England. However, there is a lack of national data on the incidence of diabetes-related amputations. The aim of this study was to describe recent trends in non-traumatic amputations in people with and without dia-

betes and estimate the relative risk of amputations in diabetes between 2004 and 2008 in England.
Materials and methods: We identified all patients who underwent any non-traumatic amputation in England between 2004 and 2008 using national hospital-activity data from all NHS hospitals. Age- and sex-specific incidence rates were calculated using the total diabetes population in England every year.
Results: Overall amputation rates (minor and major combined) decreased by 9.1%, from 27.5 per 10,000 persons with diabetes in 2004 to 25.0 per 10,000 persons with diabetes in 2008. The rate of minor LEAs fell from 15.7 to 14.9 per 10,000 persons with diabetes and major LEA rates decreased from 11.8 to 10.2 per 10,000 persons with diabetes. The absolute reductions in minor and major LEA rates were slightly greater in men with a decline from 19.9 to 18.3 per 10,000 persons with diabetes compared to a fall from 7.6 to 6.7 per 10,000 persons with diabetes in women. Poisson regression analysis showed no statistically significant change in amputation rates over time in people with diabetes after adjustment for age, sex, level of amputation and year (0.97 decrease per year 95% CI 0.92-1.02, p=0.374). Amputation rates (minor and major combined) decreased from 13.6 per 100,000 persons without diabetes in 2004 to 11.9 per 100,000 persons without diabetes in 2008. Minor and major LEA rates showed a decline from 5.9 to 5.0 100,000 persons without diabetes and from 7.7 to 6.9 100,000 persons without diabetes, respectively. Poisson regression analysis showed that the decline in non-diabetes-related LEAs did not reach statistical significance (0.96 decrease per year, 95% CI 0.93-1.00, p= 0.07). The relative risk of a person with diabetes undergoing a LEA increased slightly from 20.3 to 21.2 when compared with persons without diabetes between 2004 and 2008.
Conclusion: This national study suggests that incidence rates of lower extremity amputation in people with diabetes England remained unchanged between 2004 and 2008. The increased relative risk of amputation among persons with diabetes compared to those without appears to have marginally increased during the study period although this might be explained by decreased risk among people without diabetes.

High prevalence of limb amputation in people with diabetic foot syndrome
S. Lauterbach;
Red Cross Hospital Kassel, Germany.

Background and aims: The diabetic foot syndrome is a preventable long-term complication of diabetes mellitus. One of the St. Vincent targets from 1989 was a 50% reduction in amputation. This target is generally not reached. But to show the prevalence and incidence of limb-amputation is difficult because complete epidemiological data do not exist. The aim of the study was to show the prevalence of limb-amputation in people with diabetic foot syndrome and the mean survival time after the first diagnosis in Germany.
Materials and methods: Anonymous data were obtained from the prospectively compiled IMS Disease Analyzer database. All patients with a first diagnosis of diabetic foot syndrome between January 1, 2001 and December 31, 2005 were included. Patients were required to have continuous data for at least 5 years after the first diagnosis of diabetic foot syndrome (ID). The maximum observation period was 10 years. The primary outcome measure of the study was disease-free survival following a diagnosis of diabetic foot syndrome. The documentation of an amputation [ICD10-Codes: Z894-899] indicated the end of disease-free survival. Kaplan-. Meier plots were generated to analyse the probability of amputation and the amputation-free survival time.
Results: A total of 4,068 patients with diabetic foot syndrome were included in the analysis. The overall mean age at diagnosis was 64.9 (SD: 11.9) years, 39.2% were female, the middle HbA1c was 8.05% (SD: 2.24) and 13.1% of the patient with DFS has a polyneurpathy and 12.1% has peripheral angiopathy. 3,407 patients were in 697 general practitioner practices and 661 patients were in 57 diabetology practices. Within observation time 737 (18.1%) patients had a limb-amputation: 45.2% an amputation of foot and ankle or toes, 32.7% of leg at or below knee 18.1% of leg above knee and 4.0% amputation of both lower limbs. Limb-amputations were registered among 16.6% in general practitioner practices and 26.0% in diabetology practices, 20.2% in male and 15.5% in female patients. The mean amputation-free survival time was 7.8 years (SD: 17.2 days).
Conclusion: Results from this analysis of a large representative German database show, that the prevalence of limb-amputation in people with diabetic foot syndrome is high. Screening methods to find out high risk foot problems and appropriate education in protective foot care for people with diabetes mellitus are established but obviously not effective enough. More long lasting avoiding methods are necessary.

1149

Cost of an episode of diabetic foot ulcer in Spain
J. Marinello[1], J.R. March[2], J.I. Blanes[3], E. Martínez-Aguilar[4], J.R. Escudero[5], A. Masegosa[6];
[1]Hospital de Mataró, [2]Hospital de Getafe, Madrid, [3]Hospital Dr Peset, Valencia, [4]Hospital de Navarra, Pamplona, [5]Hospital Sant Creu I Sant Pau, Barcelona, [6]Complejo Hospitalario Universitario, Albacete, Spain.

Background and aims: The economic burden of diabetic foot is substantial, due to long term treatments, high recurrence rate and high risk of lower extremity amputation associated. In addition, diabetic foot ulcers cause high disability and decrease the health related quality of life. The objective of this study was to obtain data concerning resource consumption in patients with diabetic foot syndrome and to estimate the direct sanitary costs per patient associated to an episode of non-complicated superficial full-thickness neuropathic ulcer of diabetic foot in Spain.
Materials and methods: This is an observational, retrospective and multicenter design. Diabetics with non-complicated superficial neuropathic ulcer of at least 10 cm2 without lower extremity ischemia, and with the study ulcer completely resolved due to wound healed or amputation. Ischemic or neuroischemic ulcers or with foot infection at the time of inclusion were excluded. The study period for each patient was the duration of the complete selected ulcer episode. Collection of study data was performed in an unique visit. The estimation of costs was performed by identification and subsequent quantification of health resources used in the treatment of the diabetic foot episode, assigning a specific unitary cost to each of these resources. Analysis was carried out according to the perspective of the National Health System, taking into account direct sanitary costs, exclusively. Results are shown as total cost per ulcer episode and expressed in Euros (€) from year 2009. The study was performed from a hospital perspective.
Results: The average cost per patient with an episode of diabetic foot ulcer in Spain is estimated at 12525.12€. Only direct sanitary costs have been considered and not the indirect costs related to the loss of productivity of patients and caregivers. The hospital admissions, topical ulcer care and surgery represent the highest percentages of the direct costs, 50.4%, 19.2% and 22.8% respectively. In our study the average cost of amputations as unitary resource cost, and considering the Diagnosis-related groups values, was estimated as 7.730,14€. Taking into account the percentage of patients in the sample that suffered an amputation, this cost represent 1649.49€ per amputation (surgery procedure only) and ulcer episode. In consequence, our study could be underestimating the cost of amputations, one of the costs with highest impact in the average cost per patient.
Conclusion: Diabetic foot is one of the complications of diabetes mellitus that produces a high economic impact in the health systems. In consequence, after estimation in this study and others published in different countries, of the costs that its management involves, it would be necessary to carry out primary and secondary prophylaxis programs in order to decrease the occurrence of diabetic foot ulcers in patients with diabetes. Additionally, it would be necessary to establish an adequate management of the lesion including treatments for accelerating the healing process and cures at home in order to shorten hospital stays. By doing this, the decrease in health related quality of life of these patients would be avoided, as well as the risk of losing the extremity and also the use of the high number of sanitary resources its treatment involves.

1150

Comparison of outcome of diabetic foot ulcer treatment in 3 different centres of North West England
M.S.A. Soliman[1], G. Jones[2], E.B. Jude[3], S. Rajbhandari[1];
[1]Medicine, Lancashire Teaching Hospitals foundation trust, NHS, Chorley, [2]Medicine, East Lancashire Hospitals foundation trust, NHS, Blackburn, [3]Medicine, Tameside General Hospital, NHS, Ashton Under-Lyne, United Kingdom.

Background and aims: Diabetic foot ulcers are managed at different centres as per local protocol, which may vary from place to place depending on availability of local expertise. This may affect the outcome of ulcers. To assess this

we retrospectively studied the outcome of 50 diabetic foot ulcers that presented to 3 different centres in the North West England. The aim of this study was to assess outcome of diabetic foot ulcers in these centres.
Materials and methods: We retrospectively analysed the clinic notes of first 50 patients that attended 3 diabetic foot clinics of North West England from 1st January 2008. The list of patients that presented to diabetic foot clinic was obtained from the hospital system and their notes retrieved. Data was collected in pre-designed form. If needed other hospital IT systems were checked.
Results: Case notes of 148 patients (Mean age 66.3 +/- 12.9 years & 33.8% Females) were studied. Centre A had 46 patients (Mean age 68.7 +/- 13.2 years & 32.6% Females), Centre B had 51 (Mean age 66.0 +/- 11.4 years & 23.5% Females) and Centre C had 51 (Mean age 64.6 +/- 14.0 years & 45.1% Females) patients. There was no difference (p >0.05) in age and sex of patients between these centres. Similarly there was no difference in HbA1c, total cholesterol serum creatinine and blood pressure in patients attending these centres. Table 1 shows the results comparing these 3 centres, which clearly shows improved outcome in Centre B.
Discussion: Our study shows that there was significantly more proportion of ulcers healed by 12 weeks in Centre B, which is due to extensive use of cast and higher proportion of neuropathic ulcers. This trend of improved healing continued for 52 weeks of the study. There was no difference in the presence of infection, proportion of osteomyelitis confirmed on X-ray and amputation rate between these centres. There was a trend for reduced mortality in centre C that could be due to more proportion females in that centre.
Conclusion: This study confirms that there is variable outcome of diabetic foot ulcers even within a small geographical area. This is mainly due to variable use of cast. Similar comparative studies are necessary in order to compare quality of care provided to patients with diabetic foot ulcers.

Table (1): comparison of centre A, B, and C for different aspects of the outcome

Parameter	Centre A	Centre B	Centre C	P value
Healing by 12 weeks	34.8%	47.1%	19.6%	0.01
Healing by 24 weeks	41.3%	68.6%	47.1%	0.06
Healing by 36 weks	60.9%	76.5%	56.9%	0.09
Healing by 52 weeks	69.6%	86.3%	70.2%	0.09
Total Death by 52 weeks	4%	17.6%	17.3%	0.06
Use of Cast	23.9%	72.5%	9.8%	<0.001
Presence of Infection	56.5%	47.1%	62.7%	> 0.05
Osteomyelitis in X ray	34.8%	19.6%	19.6%	> 0.05
Neuropathic ulcers	45.7%	74.5%	52.9%	<0.01
Amputation	17.9%	15.7%	7.8%	> 0.05

1151

Diabetic foot screening: an observational study in a population of diabetics in Forli' (Northern Italy)
S. Acquati, L. Gagliardi, S. Taroni, A. Tartaglia, L. Buci, R. Manini, F. Donadio, C. Ragazzini, G. Silvani, M. Nizzoli;
Endocrinology and metabolic disease department, Forlì, Italy.

Background and aims: Diabetic foot problems are among the most serious and costly complications of diabetes. Epidemiologic reports indicate that over one million amputations are performed on people with diabetes each year. A majority of these amputations are preceded by ulcers. Despite being the most serious complications of diabetes, foot complications can be effectively prevented. Several studies show how the identification of patients at high risk of ulcer and the subsequent education of these patients represent an important step to prevent this complication.
Subjects and methods: In April 2006 in our department we start a diabetic foot screening for all diabetics followed in our clinic, in a managed care organization, in order to intensify primary prevention. Until October 2008 we evaluated 920 patients affected by diabetes (mean age 67.4±12.2 yrs, mean duration of diabetes 10.5±10.8 yrs, mean HbA1c 7.58±1.5 %). Every patient underwent accurate anamnesis, foot examination, ABI and VPT measurement, Semmes-Weinstein monofilament perception, HbA1c measurement. Patients were then stratified into 4 classes of risk according to diabetic foot international guidelines (class 0: absence of neuropathy; class I: presence of neuropathy; class II presence of neuropathy and vasculopathy and/or deformity; class III: previous ulcer or amputation).
Results: Deformities were present in 250 diabetics (27.1%), onychomycosis in 240 (26%), hyperkeratosis in 310 (33.6%), ocycochriptosis in 28 (3%). In 68 subjects we found an incidental lesion or prelesion (7.4%). 435 diabetics (47.2%) showed VPT ≥25. Monofilament was not detectable in 184 patients (19.9%). In 75 patients (8.1%) we found ABI<0,9 while in 41 (4.4%) ABI was >1,3. ABI was undetectable in 90 subjects (9.7%). Of all patients screened only 156 (17%) used proper shoes. In the table we summerised data of the different classes of risk.

Class of Risk	0	I	II	III
N° (%)	388 (42)	202 (22)	241 (26)	89 (9)
Age (yrs)	61.3±12.1	70.9±9.9	70.4±11.1	70.7±11.4
Diabetes Duration (yrs)	8.1±9.9	11.9±9.5	11.4±9.9	14.7±13.7
HbA1c (%)	7.4±1.5	7.7±1.5	7.7±1.5	7.9±1.4
microangiopathy n° (%)	80 (20)	71 (35)	74 (31)	46 (52)
macroangiopathy n° (%)	89 (23)	59 (29)	79 (33)	48 (54)

Conclusion: This study showed a high prevalence of diabetics at risk of ulcer and underlined the importance of an accurate screening in all diabetics at least once. The subsequent classification of the patients in different classes of risk is an important step in order to strengthen both educational and therapeutical strategy in those patients at higher risk of developing ulcers. Our data showed that many patients are not at glycaemic target and underlined the necessity to intensify treatment both in low risk classes, in order to really prevent the development of complications, and in high risk classes, in order to reduce the progression of the complications already present.

1152

Characteristics of diabetic charcot foot in Western Pacific region - ASIPAC foot study 2
S. Kono[1], R. Nakagawachi[1], E. Yunir[2], G.Z. Zhao[3], H. Kajio[4], M. Noda[4], Y. Seino[5], M. Hattori[6], H. Kuzuya[1], B.V. Ta[7], E.A. de Jesus[8], S. Krittiyawong[9], A.J. Boulton[10];
[1]WHO-collaborating Centre for Diabetes, Kyoto, Japan, [2]Internal Medicine, University of Indonesia, Jakarta, Indonesia, [3]Henan Provincial People's Hospital, Zhengzhou, China, [4]National Center for Global Health and Medicine, Tokyo, Japan, [5]Kansai Electric Power Hospital, Osaka, Japan, [6]Division of Diabetes, Kyoto Medical Center, Japan, [7]Hanoi Medical University, Viet Nam, [8]Orthopedics and traumatology, Jose R., Reyes Memorial Center, Kyoto, Philippines, [9]Theptarin Hospital, Bangkok, Thailand, [10]Universities of Manchester and Miami, United Kingdom.

Aims: The aim of this study (ASIPAC FOOT STUDY-2) was to investigate the characteristics of diabetic patients with Charcot foot in 6 tertiary care hospitals in 6 countries (Thailand, Indonesia, China, Philippines, Vietnam and Japan), and to increase awareness of diabetic Charcot foot problems in Western Pacific Region (WPR).
Methods: The study population includes 54 patients presenting with Charcot foot. Data on patient characteristics, as well as foot characteristics were obtained.
Results: General patient characteristics were different in some points between countries. The patients at the onset were in their fifties in most countries except China (average age (years): 50.0 in Philippines (P), 50.7 in Japan (J), 52.9 in Thailand (T), 53.3 in Indonesia (I), 56 in Vietnam, and 65.2 in China (C)). Body mass index (BMI) was lower than 26.0 kg/mm^2 in most countries (mean BMI: 22.4 in V, 25.0 in J, 25.9 in P, 25.9 in C 25.8 in I and 28.4 in T). Most patients have past history of foot ulcer and amputation before the onset (ulcer (%) / amputation (%): 100/42.9 in C, 100/28.6 in I, 61.5/23.1 in T, 50/5 in J, 40/0 in P, 0/0 in V). Many patients in hot countries such as Philippines, Thailand, Indonesia and Vietnam walked with sandals before the onset. It took a long time until the diagnosis of Charcot foot after the onset (average months: 10.9 in T, 5.7 in J, 4.7 in C, 3.1 in I, 2.2 in P and 0.5 in V). About 50% were diagnosed after presenting with mid-foot deformity together with ulcer (at diagnosis, stage 0 (prodromal period): 1.9%, stage 1 (development): 41.5%, stage 2 (coalescence): 5.7%, stage 3 (reconstruction): 50.9% / location (%) : forefoot: 15.8, mid-foot: 59.7, hindfoot: 24.6 / prevalence of ulcer (%) : 71.4 in C, I, and T, 30 in J, and 20 in P). Even after the initiation of the treatment of Charcot foot, many patients showed the progression of foot deformity, chronic foot ulcer and were undertaken amputation (progression of deformity (%): 42.9 in I, and C, 25 in T, and 5 in J / chronic ulcer (%): 90 in T, 66.7 in C, 71.4 in I and 15 in J / amputation (%): 100 in P, 30.8 in T and 14.3 in C). Most patients were not provided with custom-made footwear despite severe foot deformity.
Conclusion: Characteristics of Charcot patients in the WPR differed from those in Western countries in that the BMI was lower, the diagnosis was made later and the overall prognosis was poorer. It is very likely that there are many

more cases of Charcot foot that are misdiagnosed or undetected in the WPR. In order to improve prognosis and reduce amputations in the WPR, it is essential to have a high index of suspicion for Charcot foot, increase awareness of it and to encourage early presentation of the patient.

Brachial-ankle pulse wave velocity predicts healing of diabetic foot ulcers among patients with type 2 diabetes
D. Cho, J. Chung, D. Chung, M. Chung;
Department of Internal Medicine, Chonnam National University Hospital, Gwangju, Republic of Korea.

Background and aims: Some 7-10% of diabetic patients develop chronic foot ulcers, a severe and expensive complication that leads to minor or major amputation in 10-15% of the patients. Peripheral arterial occlusive disease contributes to the impaired healing process. Measurement of pulse wave velocity (PWV) is a useful non-invasive index of arterial distensibility, and predicts cardiovascular morbidity and mortality. Several studies demonstrated that pulse wave velocity a sensitive predicator for peripheral artery disease and cerebrovascular disease among diabetic patients. The objective of this study was to determine whether brachial-ankle pulse wave velocity (baPWV) can predict healing of diabetic foot ulcers.
Materials and methods: We recruited a total of 86 type 2 diabetic patients (52 men and 34 women) with chronic foot ulcers. The age was 62.7±12.3 years, and the diabetes duration was 15.6±11.2 years. Anthropometric, clinical, and laboratory data were measured. All patients were seen weekly for debridement, offloading, and other treatments during the initial 8 weeks. The PWV was measured between the brachial and ankle regions (baPWV), and the baPWV was measured in all patients using a waveform analyser.
Results: At 8 weeks, 31 of the 86 ulcers had completely healed. The 86 patients were divided into two groups according to the clinical outcome of ulcer healing at 8 weeks. There were no differences in age, duration of diabetes, HbA_{1c}, or initial size of the ulcer between the healed and unhealed groups. The healing time of foot ulcers in healed group was 5.2±2.3 weeks (range 1.2-7.7). The baPWV was significantly ($P<0.05$) higher in the unhealed group (1768±290 cm/s) as compared with the healed group (1553±312 cm/s). Age ($r = 0.504$; $p< 0.01$), duration of diabetes ($r = 0.279$; $p< 0.05$), ankle-brachial index (ABI) ($r = -0.328$; $p< 0.05$) and toe-brachial index (TBI) ($r = -0.281$; $p< 0.05$) were significantly correlated with baPWV. But BMI, lipid profiles, HbA_{1c}, and systolic and diastolic BP were not correlated with baPWV. Univariate analysis revealed that baPWV was significantly correlated with healing rate of diabetic ulcers ($r = 0.283$, $p < 0.05$) and age ($r = 0.452$, $p < 0.01$).
Conclusion: We report that increased baPWV is closely associated with the healing time of diabetic ulcers. Our results suggest that the degree of systemic arterial stiffness is predictor of the healing of diabetic ulcers in patients with type 2 diabetes.

1154

Does the type of off-loading have any impact on the quality of life in patients treated for the diabetic foot?
V. Fejfarova[1], A. Jirkovská[1], E. Dragomirecka[2], R. Bem[1], M. Dubský[1], V. Woskova[1], V. Lanska[1];
[1]Diabetes Center, Institute for Clinical and Experimental Medicine,
[2]Psychiatric Center, Prague, Czech Republic.

Background: We often meet in patients with the diabetic foot ulcers (DFU) with invalidisation, higher morbidity and mortality that could lead to deterioration of quality of life (QoL) and enhancement of depression scale. However, there exist extensive inter-individual psychological differences even in patients with DFU that could be influenced by variety of external factors including the method of DFU off-loading which affects patient's mobility, social relations, employment possibilities, etc.
Aims: In our study we assessed the differences in QoL and depression scale in relation to the type of DFU off-loading and DFU duration between patients with DFU treated by half shoes, orthoses and wheelchairs.
Methods: In total, 48 patients with chronic DFU (mean age 60.6±9.4 years, 77% of males, 80% of patients with Type 2 diabetes, mean diabetes duration 20.5±9.6 years, mean DFU duration 16.5±18.7 months) treated in our outpatient foot clinic from 1/2010 to 3/2010 were consecutively included into our study. Patients were divided into 3 study groups according to the type of using off-loading device - patients treated by half shoes (HS group - 26), by different types of orthoses including TCC (O group - 10) and by wheelchairs (WCh group - 12). QoL was evaluated by standardize questionnaire WHO-QoL-Bref assessing 4 domains (physical capacity, psychological well being, social relationships and environment). Depression scale was assessed by Gender Depression Scale (GDS).
Results: The WCh group did not differ significantly in the depression scale when compared to the HS and O groups (mild form of depression was presented in 85.7% vs. 82.6% vs. 100% of patients; NS; no severe form of depression was found in all study subjects). Moreover, in particular domains of the WHOQoL-Bref, the results of WCh group were similar to the HS and O group (physical capacity-12.5±3.5 vs. 12.3±2.7 vs. 12.7±3.2; psychological well being-14.3±3.1 vs. 14.7±2.7 vs. 15.1±1.6; social relationships-15.3±4.7 vs. 14.7±2.7 vs. 13.5±1.8; environment-14±2.6 vs. 14±2.1 vs. 14.6±1.5; all NS). Study groups differed significantly only in DFU duration (7.3±7.8 in WCh group vs. 14.5±15.9 in HS group vs. 33±25.9 months in O group; $p< 0.01$); other evaluated parameters did not differ significantly between the study groups. Suicidal tendencies and pain symptoms were described in 9.1% (4/44) and 56.1% (23/41) of all questioned patients.
Conclusion: The type of off-loading device including wheelchairs did not influence significantly QoL nor depression scale in patients treated for DFU. We suggest the DFU duration rather than the type of DFU off-loading has a greater impact on QoL and depression in diabetic foot patients.

The study on mechanisms of epidermal keratinocyte migration impaired by glycated matrix

Z. Song[1], Y. Demin[1], W. Runxiu[2], T. Ming[3], X. Ting[3], H. Fei[2], Y. Guozhi[2], L. Shuliang[3];
[1]Key Lab of Hormones and Development, Ministry of Health, China, Tianjin, [2]First Affiliated Hospital of Guangxi Medical University, Nanning, Guangxi Zhuang Autonomous Region, [3]Ruijin Hospital, Shanghai Second Medical University, China.

Background and aims: Diabetes mellitus is one of the most common disease in human life. Many kinds of complications caused by diabetes metabolism disorder and its metabolite, including nonhealing wound, now is becoming a difficulty in clinical treatment and academic research. Keratinocyte is the mainly repair cell participating wound healing, whose migration function is the base of wound re-epithelization. Keratinocyte continuously migrates on the wound edge, while wound size reduces to complete healing. If keratinocyte migration is blocked, then it means that the wound can't heal. So the study of keratinocyte migration behavior is of profound significance for exploring the rule of wound healing. This study is to discuss that keratinoctye migration is impaired by glycated matrix and its mechanism.
Materials and methods: Keratinocytes from six male Sprague-Dawley rats' back, cultured for two to three generations, were used for experiments. Glycated laminin model were made by laminin cultured in glycolaldehyde and AGEs concentrations were assessed by detecting total fluorescence in glycated laminin model and immunohistochemistry assay. Keratinocytes were cultured on glycated laminin and normal laminin as study group and control group respectively. Keratinocyte migration was measured by scratch wound healing assay. Adhesion rate was expressed by Optical Density(OD), determined with MTT assay. Keratinocyte morphous was observed by scanning electron microscopy and inverted microscope. F-actin was observed by immunofluorescence. Integrinα3 was determined by flow cytometry.
Results: The amount of migrating keratinocyte in study group is significantly less than control (13±4/HP vs 61±11/HP, P<0.05), which confirmed that keratinocyte migration was obviously inhibited by glycated matrix. There was no difference of adhesion rate between study group and control group(12h OD: 0.102±0.014 vs 0.134±0.062; 24h OD: 0.181±0.050 vs 0.187±0.061,P>0.05), however the morphous of keratinocyte on glycated laminin indicates that the cell body was small and hardly spread compared with that on normal laminin. Microfilament of the keratinocyte on the glycated laminin was sparsely distributed in the cytoplasm and around cell nuclear, but the expression of microfilament in the control group was intensively and distributed on the cell membrane, especially on the free edge. The expression of keratinocyte integrinα3 on normal laminin is significantly higher than that on glycated laminin(11.23±5.27% vs 36.58±11.24%, P<0.05).
Conclusion: Keratinocyte migration is inhibited by the glycated laminin. The reason behind the phenomenon is possibly that integrin signaling disorder leads to decrease of integrin and actin expression, followed by the drop of lamellipodia and filopodia development, and the ultimate consequence would be the contribution to the restrained migration.

IGF-1 is a mediator of inflammation in Charcot Neuroarthropathy and could play an important role in its pathogenesis

T. Musella[1], D. Pitocco[1], F. Zaccardi[1], G. Pozzoli[2], M. Galli[3], C. Torriani[2], G. Tringali[2], C. Dello Russo[2], G. Scavone[1], S. Caputo[1], G. Ghirlanda[1];
[1]Internal Medicine, [2]Pharmacology, [3]Orthopedic Surgery, Catholic University, Rome, Italy.

Background and aims: Charcot neuroarthropathy (CN) is a multifactorial disease in which genetics of the axis RANK-RANK-L- osteoprotegerin and a dysregulation of inflammation seem to be involved. A simultaneous improvement of bone mass density of the foot and a reduction of IGF-1 levels was showed after a treatment with alendronate. Aim of this study was to investigate the possible role of IGF-1 in the modulation of inflammation in CN and further support the functional involvement of the axis RANK-RANK-L-osteoprotegerin (OPG) in its pathogenesis.
Materials and methods: Monocytes were obtained from peripheral blood of 10 healthy Donors (C), 10 subjects with CN not in acute phase and 10 subjects with diabetic neuropathy (DN) but without CN. They were incubated with LPS, that is an inflammatory stimulus and in vitro inhibits RANK rna expression, or IGF-1 and then was measured the production of RANK (expressed as percentage variation compared to C) and prostaglandin E2(PGE-2) levels (RIA method, pg/ml) as marker of inflammatory activation.
Results: At baseline there were no differences about Rank expression and PGE-2 levels among CN, ND and C. After incubation with LPS, CN showed a significant smaller reduction of RANK compared to ND and C, while there were not significant differences about PGE-2 levels, although they were slightly higher in CN (402.2 ± 35.64 vs 353.2 ± 40.88 in C and 381.6 ± 54.87 in ND). After incubation with IGF-1 there were not significant differences about RANK expression among three groups while CN showed a significant increase of PGE-2 levels (144.9 ± 30.93) if compared to DN (46.33 ± 12.24) and C (28.89 ± 6.24) p<0.01.
Conclusion: This study seems to support for the first time the possible involvement of IGF-1 as mediator of inflammation, demonstrated by the increased production of PGE-2 after its stimulus, in the pathogenesis of CN, and further confirm the pivotal role played by the axis RANK-RANK-l-OPG.

1157

Wound healing is selectively modulated by estrogen receptors in diabetes

V.G. Sunkari[1], J. Grünler[1], S. Lindberg[1], I.R. Botusan[1], O. Savu[1], K.R. Steffensen[2], K. Brismar[1], S.-B. Catrina[1];
[1]Department of Molecular Medicine and Surgery, [2]Department of Biosciences, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Impaired wound healing in diabetes is a major medical and economical problem. It is therefore a need to find new therapeutical approaches. The effects of estrogen on cutaneous wound healing are well established and it might explain the defective wound healing in elderly. Estrogen receptors beta (ERβ) have been linked to venous ulcers. However, the effect on diabetic wounds is still unexplored. The present study analyzed the contribution of the Estrogen receptors (ERα and ERβ) to wound healing in diabetic mice.
Materials and methods: We studied the effect of streptozotocin induced diabetes on wound healing rate in estrogen receptor knock out (ERα-ERKO & ERβ-BERKO) and in wild type mice (C57BL/6). The wound model consists of full-thickness wounds made on the dorsum of the animals. The wound area were determined every second day using a digital camera. Wound granulation, dermal and epidermal regeneration were evaluated by hematoxylin and eosin staining and angiogenesis by GS-1 isolectin staining. Markers for inflammation, endothelial precursor´s cell recruitment and cell migration were analyzed by qRT-PCR. Invitro cell migration assay was carried out in Human dermal fibroblasts (HDFs) in order to determine rate of migration in presence of agonists for estrogen receptors alpha and beta.
Results: Diabetic BERKO mice but not diabetic ERKO mice have a faster wound healing rate compared to diabetic wild type mice (50% wound closure at 3.4 +/- 0.3 days (p<0.05), 4.5 +/- 0.5 days respectively 4.7 +/- 0.5 days). HDFs treated with either specific alpha or beta estrogen receptor agonists showed a significant increase in migration rate.
Conclusion: After induction of diabetes β-receptor knock-out (BERKO) mice display an accelerated wound healing rate when compared to α-receptor knock-out (ERKO) or wild type mice (C57BL/6). These data suggest the use of specific ER agonists for therapeutic trials. The different effect of the ERs on wound healing rate is not due to a specific effect on fibroblast migration rate.

Emotional distress may impede diabetic foot ulcer healing through elevated levels of interleukin-6: preliminary findings

L. Vileikyte[1], B.-J. Shen[2], M.J. Hardman[3], R.S. Kirsner[4], A.J.M. Boulton[1], N. Schneiderman[5];
[1]Medicine, University of Manchester, United Kingdom, [2]Psychology, University of Southern California, Los Angeles, USA, [3]Life Sciences, University of Manchester, United Kingdom, [4]Dermatology, University of Miami, USA, [5]Psychology, University of Miami, USA.

Background and aims: Emotional distress induced up-regulation of Interleukin-6 (IL-6) has been found to be detrimental to health. As diabetic foot ulcers are characterized by chronic inflammation, it is plausible that emo-

tional distress could delay the healing of such ulcers by up-regulating and sustaining high levels of pro-inflammatory cytokines such as IL-6.
Materials and methods: Forty five type 2 DM patients (76% male; mean age 55yrs) with plantar neuropathic diabetic foot ulcers (University of Texas Classification: 82% grade 1A; 12% 1B; 3% 2A; and 3% 2B) completed at baseline the self-report measures both of generalized emotional distress (Perceived Stress Scale, PSS: 1.3±0.8 and Hospital Anxiety and Depression Scales: HADS-Anxiety: 13.5±4.4; HADS-Depression: 11.7±5.0) and foot ulcer-specific emotional responses (Neuropathy and Foot Ulcer-Specific Quality of Life, NeuroQoL-Interpersonal Burden scale: 3.7±1.2 and Patient Interpretation of Neuropathy, PIN, scales: PIN-Amputation Worry: 4.1±0.8; PIN-Anger at Practitioners: 2.3±1.0). Ulcer-specific IL-6 levels were determined via quantification of immunohistochemical wound biopsy tissue localization; systemic IL-6 was measured from patient serum via enzyme-linked immunosorbent assay.
Results: In the bivariate analyses, more severe generalized and foot-ulcer-specific emotional distress was associated with higher baseline levels of ulcer biopsy log-transformed IL-6 (raw mean: 608.3±545.5 cells/mm2): HADS-Anxiety (r=0.44; p=0.031), PSS (r=0.44; p=0.034), PIN-Amputation Worry (r=0.54; p=0.007) and NeuroQoL-Interpersonal Burden (r=0.60; p=0.004). Similarly, more severe PSS (r=0.35; p=0.05), PIN-Anger at Practitioners (r=0.33; p=0.03) and NeuroQoL-Interpersonal Burden (r=0.39; p=0.03) were associated with higher baseline serum IL-6 levels (mean: 8.9±4.2pg/ml). Furthermore, patients with higher baseline levels of serum IL-6 were less likely to achieve 80% or greater wound area reduction at 6 weeks (r=-0.35; p=0.03).
Conclusion: These preliminary findings suggest that emotional distress-related IL-6 up-regulation may be one of the mechanisms linking psychological stress to chronicity of diabetic foot ulcers.

Characterisation of circulating stem and progenitor cells in type 2 diabetic patients with foot ulceration
T. Koblik[1], E.K. Zuba-Surma[2], P. Witek[1], W. Nowak[2], A. Jozkowicz[2], M.T. Malecki[1], J. Dulak[2];
[1]Department of Metabolic Diseases, [2]Department of Medical Biotechnology, Jagellonian University of Krakow, Poland.

Background and aims: Type 2 diabetes (T2DM) is a major health problem in Europe due to severe complications, for example the diabetic foot syndrome (DFS). Ulcerations that are often difficult to heal. Their pathogenesis may be associated not only with metabolic abnormalities but also with alterations in stem and progenitor cell mobilization. It has been shown that both the functionality and the number of endothelial progenitor cells (EPC) circulating in peripheral blood (PB) are altered in diabetic patients. However, other stem cell (SC) populations potentially involved in wound healing and regeneration such as i) mesenchymal SC (MSC) and ii) adult pluripotent SC (PSC), including very small embryonic-like (VSEL) SC, have never been examined in T2DM. Aim of the study was to examine the phenotype and level of SC circulating in PB in T2DM subjects with and without DFS as compared to healthy controls.
Materials and methods: Three groups of subjects were included: a) T2DM patients without DFS (n=9); b) T2DM with DFS with ulceration(s) (n=3), c) controls without diabetes (n=4). We employed flow cytometry to evaluate the presence of the following SC populations based on the surface markers: i) EPC (CD31+CD133+CD45-, CD31+KDR+CD34+CD45-); ii) MSC (STRO-1+CD105+CD45-, CD90+CD29+CD45-) and PSC (Lin-CD45-CD133+, Lin-CD45-Tra1.81+).
Results: We found that when compared to healthy subjects, the number of EPC was decreased in both T2DM groups (w/o and with DFS) (9.6±2.1, 5.3±0.7* and 3.4±2.3 of CD31+CD133+CD45- cells/1ml PB, respectively). Similarly, the number of MSC were smaller in both T2DM groups (6.4±1.1, 3.9±0.5* and 2.2±0.4 of STRO-1+CD105+CD45- cells/ 1ml PB, respectively). Interestingly, the numbers of PSC was slightly decreased in healthy controls as compared to T2DM patients (0,27±0.7, 0.30±0.08 and 0.38±0.07of Lin-CD45-CD133+ cells/ 1ml PB, respectively). * P<0.05 vs. control.
Conclusion: For the first time we characterized several subsets of SC circulating in the blood of T2DM patients. Our initial results indicate that as compared to healthy controls, their mobilization may be different, particularly in the subgroup with DFS and ulceration; a potential pathogenic role of this phenomenon should be considered.

The diabetic foot: relevance of endothelial progenitor cells as a prognostic marker of mortality and disease progression
O. Fortunato[1], G. Spinetti[1], D. Cordella[1], P. Portararo[1], E. Faglia[1], P. Madeddu[2];
[1]IRCCS MultiMedica, Milan, Italy, [2]University of Bristol, United Kingdom.

Background and aims: Ischemic diabetic foot ulcers represent an unmet clinical need. To date, the prediction of clinical outcome relies on clinical data rather than on endogenous repair mechanisms. Circulating endothelial progenitor cells (EPC) are implicated in healing processes but reduced in patients with diabetes and inversely correlated with severity of vascular complications. Here, we report the preliminary results of a longitudinal study aimed to verify whether the abundance and functional activity of EPCs predict major endpoints such as amputation and post-angioplasty restenosis.
Materials and methods: The project was designed to enrol 109 diabetic (type 1 and 2) patients and 30 age- and sex-matched non-diabetic subjects referring to our Institution for chronic critical ischemia as defined by the guidelines of the Inter-Society Consensus (TASC) for the management of peripheral artery disease. Baseline testing includes measurement of glycemia, HbA1c, echo-doppler, transcutaneous oximetry (TO) and angiography. A blood sample (30mL) is obtained for isolation of mononuclear cells (MNCs). The migratory activity of isolated MNCs is measured in a transwell migration assay using SDF-1α (100ng/ml) as a stimulus. The antigenic profile of freshly isolated and migrated/non migrated MNCs is evaluated by flow cytometry. All patients are subjected to percutaneous angioplasty and follow up visits are scheduled at 1, 3, 6, 12 and 18 months.
Results: Thirty-four diabetic patients and seven non-diabetic subjects were enrolled to date with an average follow up of 7 months. No fatal event was recorded; 1 major amputation and 5 restenosis occurred in the diabetic group. The number of MNCs did not differ between the 2 groups. EPCs (CD34+KDR+CXCR4+CD45low) tended to be reduced in diabetic (0.009±0.002% vs. 0.012±0.003% in non-diabetic p=0.4). In non-diabetics, SDF-1α stimulation resulted in a 2-fold enrichment of EPCs in the migrated fraction, whereas the response of diabetic EPCs to SDF-1α was totally abrogated. With regard to clinical endpoints, complications were associated with a higher migratory activity of lineage-positive subpopulations of the MNC pool, whereas no difference was found in the number and migratory activity of EPCs. Ad interim analysis of independent variables (number and migratory activity) indicates that the designed study is adequately powered to reach definite conclusions on the predictive value on major endpoints.
Conclusion: This is the first longitudinal study assessing the predictive value of circulating progenitor cells in patients with foot ulcers and critical limb ischemia. Results indicate that diabetes impairs the migratory deficit of circulating progenitors and that unbalanced migratory activity of different MNC subfractions may be associated to a higher risk for complications in the diabetic cohort. Our preliminary data also indicate that the study has enough power to determine whether circulating progenitor cells may represent a valuable biomarker of vascular events in patients with foot ulcers undergoing revascularization.

Explanations for lower peak plantar foot pressures in Indian Asians versus Europeans with type 2 diabetes
C.A. Abbott[1], S. Naqvi[1], N. Chaturvedi[2], R.A. Malik[1], A.J.M. Boulton[1];
[1]Cardiovascular Research Group, University of Manchester, [2]National Heart & Lung Institute, Imperial College, London, United Kingdom.

Background and aims: Risk of diabetes-related foot ulceration and amputation is substantially lower in Indian Asians versus White Europeans in the UK. We have also recently demonstrated that neuropathy (large and small fibre) is less prevalent in Asians, probably accounting for much of the reduced Asian ulcer risk. We now aimed to: (i) compare peak plantar foot pressures, an established risk factor for ulceration, in Indian Asian and European diabetic subjects; (ii) explain any ethnic pressure differences found.
Materials and methods: From our cross-sectional study of a population-based sample of age- and sex-matched adults with type 2 diabetes of European and Asian descent in the UK, a random sub-cohort of 104 Europeans (50 female: 54 male) and 105 Indian Asians (36 female: 69 male) underwent plantar foot pressure measurements using the semi-quantitative PressureStat® system. Ethnic differences in peak pressures were determined at the meta-

tarsal heads, great toe, second toe and heel. Comparisons with a group of 34 age-matched, non-diabetic control subjects (European (12 female: 5 male) and Asian (7 female: 10 male)) were also sought.
Results: Peak pressures (>6kg/cm^2) at metatarsal heads 1, 2, 3, and 5 were consistently more prevalent in the European vs. Asian diabetic group ($p<0.01$). Furthermore, 32% Europeans had ≥4 peak pressure sites compared with just 6% Asians ($p<0.0001$). Logistical regression analysis revealed that fewer peak pressures in Asians vs. Europeans could be partly explained by Asians' lower weight, less plantar callus and more vigilant footcare (attenuating the Odds Ratio from 0.13 (0.05-0.32, 95% CI; $p<0.0001$) to 0.28 (0.10-0.78; $p=0.014$)), however most of this ethnic difference remained unaccounted for. Asian and European control groups showed a consistent trend for fewer peak pressures at plantar sites than their diabetic counterparts, yet peak pressures at the great toe were, conversely, greater. PressureStat® demonstrated a high degree of intra-user agreement with 97.4-99.0% of scores within one range of each other on re-scoring.
Conclusion: Type 2 diabetic Indian Asians have significantly lower peak plantar pressures than their European counterparts, which can, in part, be attributed to lower weight and less plantar callus in Asians. These data may further help explain the substantially reduced Asian foot ulcer risk.

Methicillin resistant staphylococcus aureus in diabetic foot ulcers of a Chinese care hospital: risk factors for infection and prevalence
S. Wang[1], Y. Guo[2], Y. Yuan[1], Z.-L. Sun[1];
[1]The Department of Endocrinology, [2]Department of Neurology and Institution of Cerebral Vascular Disease, affiliated ZhongDa Hospital of Southeast University, NanJing, China.

Background and aims: Retrospective case-control study of 118 (M: F, 68:50) Chinese type 2 diabetic patients with foot ulcers (Wagner's grade 3-5) were studied to determine the prevalence and risk factors for methicillin-resistant Staphylococcus aureus (MRSA) infection, in relation to community or hospital original parameters.
Materials and methods: Ulcer specimens were processed for smear for Gram's staining, aerobic culture, and susceptibility identifications. Staphylococcus species were tested for methicillin resistance by using oxacillin.
Results: S.aureus was the most frequent pathogen (25.6%) in this population, a high proportion of S.aureus isolates were MRSA (63.4%). 65.4% met the definition of hospital associated MRSA (HA-MRSA) infections. Size of ulcer (adjusted OR 1.61; 95% CI 1.22-2.12) and osteomyelitis (adjusted OR 18.51, 95% CI 2.50-137.21) were independent predictors of MRSA infection. The HA-MRSA group had significantly different distributions from the community associated MRSA (CA-MRSA) group with respect to age, long history of diabetes, and length of hospital stay (all P<.001). Neuropathy, vascular disease (all P= .049), and osteomyelitis (P= .026) were the most common underlying conditions observed in the HA-MRSA group.
Conclusion: This study makes contribution to precaution against the emergence of MRSA including different acquired MRSA among the Chinese population with diabetic foot ulcers based on their original or clinical parameter.

The influence of contrast medium on renal function in diabetic patient with critical limb ischaemia after contrast angiography/peripherial transluminal angioplasty
O. Bondarenko, K. Pryakhina, I. Sitkin, G. Galstyan, I.I. Dedov;
Department of the Therapeutic and Surgical treatment methods of Diabetic foot, Research Center of Endocrinology, Moscow, Russian Federation.

Background and aims: The aim of the study was to assess the renal function of diabetic patient with critical limb ischemia (CLI), who underwent contrast angiography (CA)/peripherial transluminal angioplasty (PTA) before and after administration contrast medium (CM).
Materials and methods: 82 patients with PAD recruited in the study (mean age 65±17 years; male/female 47/53%; Type 2 DM 92%; mean diabetes mellitus (DM) duration 17±10 years). Peripherial artery disease was assessed by palpation of pedal pulse, ankle brachial index (ABI) measurement, doppler, transcutaneous oximetry (TcPO2) and duplex scanning (DS). Patients were divided according frequency and volume of CM and accuracy of DS results into 3 groups. The groups were matched by type of DM, age, duration of DM, sex. Group A (n=28) were underwent CA with the mean volume of CM 200 ml and consecutively PTA with the mean volume CM 130 ml. In group B (n=36) endovascular revascularizations were performed with the mean volume CM 130 ml without CA, because of highly valuable of DS results. In group C (n=18) multiple CA and PTA were done with the mean volume CM 480 ml summary. Glomerular filtration rate (GFR calculated by MDRD equation) assessed before and after administration CM on 3-5 days and in a 14 months in all groups.
Results: Initial albumin excretion rate (AER) and GFR were not different in comparing groups. The decrease of mean GFR was 20,2±2,1 ml/min/1.73m^2 in group A; 14,3±1,7 ml/min/1.73m^2 in group B; 19,1±1,9 ml/min/1.73m^2 in group C on 3-5 days after administration of CM. $p_{A-B}<0.01$, $p_{A-C}<0.2$, $p_{B-C}<0.01$. The decrease of mean GFR was 22,2±1,6 ml/min/1.73m^2 in group A; 15±1,6 ml/min/1.73m^2 in group B; 24±1,7 ml/min/1.73m^2 in group C in a 14 months. $p_{A-B}<0.01$, $p_{A-C}<0.2$, $p_{B-C}<0.01$. 1 case of contrast-induced acute renal failure was registered in group A. Microalbuminuria progression according AER was observed in 3 cases in group A and in 2 cases in group C. Neither AER progression nor renal failure were documented in group B. The accuracy and sensitivity of duplex scanning was comparable in the selection of aorto-iliac lesions (86% and 88%) and femoro-popliteal lesions (91% and 93%) in A and B groups, but in infrapopliteal axis these characteristics were significantly higher in group B versus group A, 90% and 78%, respectively.
Conclusion: The results of this study showed that the risk of progression diabetic nephropathy in patients with CLI after CA/PTA increased and depend on frequency and volume of CM. The high accuracy DS in diabetic patients with CLI permits to reduce the frequency of preliminary angiography and prevent the development of deteriorating of renal function.

PS 114 Diabetic foot - treatment

Podiatric insoles cause foot ulcers in diabetic patients

M. van Putten[1], P. Leffers[2], N.C. Schaper[3];
[1]School of Podiatry Eindhoven, [2]Epidemiology, University Maastricht,
[3]Internal Medicine, Maastricht University Medical Center, Netherlands.

Background and aims: Inadequate footwear is an important contributor of foot ulceration in diabetic patients with polyneuropathy and prescription of protective footwear is seen as a cornerstone in preventing ulcers. In several countries preventive diabetic foot care is provided by podiatrists, who can also prescribe insoles. However, recent publications have casted doubt about the effectiveness of these insoles to reduce plantar pressure. Therefore we studied the effect of podiatric insoles on the incidence of diabetic foot ulcers.
Materials and methods: This study was part of the Podopoof trial; in this RCT we compared podiatric (n=284) with usual care by diabetologists (n=285), in diabetic patients with neuropathy and moderate risk (category 2 IWDGF) for ulceration. Podiatric care consisted of ≥ 2 consultations/year and included preventive foot care as well as prescription of podiatric insoles to reduce plantar pressure, if deemed necessary. New cases of diabetic foot ulcers were ascertained during a follow-up period of up to 3 years.
Results: As reported earlier no difference were observed in ulcer incidence between the podiatry and usual care groups, 28 vs 30; data of the intervention and control group were therefore combined. The mean age was 63 years, the modified neuropathy disability score was 3,1, 52% were male. Insoles were prescribed in 184 patients, 177 (62%) in the podiatry and 7 (2%) in the usual care group. Of the patients with an ulcer 65% had insoles. Of the patients with insoles 22 (12%) developed an ulcer, while this occurred in 6 (1%) without insoles (p<0.01). Multivariable Cox regression analysis showed that the time to ulceration in the insole-group is shorter than in the non-insole group. Subgroup analysis showed that men develop more ulcers than women and that the detrimental effect of insoles was also larger in men.
Conclusion: Prescribing preventive insoles for diabetic patients with moderate risk for ulceration with the goal to prevent ulceration can have opposite effects: in the insole-group more ulcers occurred than in the non-insole group. It is our belief that podiatrists should not prescribe insoles in these patients to prevent ulceration.

Rate of relapses diabetic osteoarthropathy and its dependence on the terms and a carrying mode of weight-bearing bandage TotalContactCast at patients with acute Charcot foot

M. Vanyan, I. Ulyanova, G. Galstyan, M. Yaroslavtseva;
Therapeutical and Surgical treatment methods of Diabetic Foot, Scientific research Center of Endocrinology, Moscow, Russian Federation.

Background and aims: The aim was to estimate the results of the treatment Charcot foot (Ch.f) in type 1 and 2 diabetic patients with weight- bearing by TotalContactCast at acute stage of Ch.f.
Materials and methods: In total 47 patients with diabetes mellitus (DM) 1 type (n = 21) and 2 types (n=26), mean age of patients - 49,7 ±13,8 years. All patients divided in 2 groups by temperature criteria: group 1 at 22 patients (Δtº- 5,7º±2,7), and Group 2 - at 25 (Δtº-4,2±2,1). Mean of HbAlc at patients in Group 1 was 9,3 ± 2,34 %, in Group 2 - 8,7 ± 1,6. Difference between occurrence of clinical symptoms diabetic osteoarthropathy and start of treatment was 10,5 ±9 month at patients in group 1, 19,7±15,9 years at patients in group 2. To all patients duration with treatment by TotalContactCast of group 1 was 4,9 ± 1,8 month, in group 2 -7,7 ± 3,6 month. To all patients' correction of therapy diabetes mellitus (DM) metabolic control has done. Differences between groups were examined by using Fisher criteria, significance level is p<0,05. Duration of follow-up period was 24 ± 2.4 months.
Results: In 24 months the decrease of Δ HbAlc achieved at patients in group 1 - 7,2 ± 1,53%, and 6,9 ± 1,9% in group 2. From 47 patients, 68 %(n=32) had good compliance of caring TotalContactCast and at 28% (n=9) relapse osteoarthropathy was observed. 31% of patients (n=15) didn't follow the term of recommended treatment and the relapse of osteoarthropathy was significantly high and observed in 67 % cases (n = 10); remission in 23%, (p = 0,023). In group 1- 22 patients only 63 % (n =14) followed recommendations about carrying period of TotalContacCast and unloading, thus relapse in group 1 observed at 43 % (n=6). Significantly associated in 36 % (n=8) patients, who stopped therapy before term, relapse was revealed at 62 % of patients (n=5), (p = 0,008). In group 2 of 25 patients - of 72 % (n=18) followed the term of carrying TotalContactCast and lower extremity unloading (relapse - at 17 % of patients, n=3). From 28 % (n=7) the patients without observing a mode of unloading, in 71 % of cases (n=5) relapse osteoarthropathy (p = 0,037) is revealed.
Conclusion: Weight-bearing bandage is a highly effective method of treatment of the first choice for therapy Charcot foot: remission of the complication is reached in 72 % of cases, in both groups. At non-observance of conditions fixating therapies remission in 2 year evaluating period makes only 23 % of investigated patients. Thus, the mode of weight-bearing and its duration is crucial to lower the relapse rate of diabetic patients with acute osteoarthropathy, within glycemic control.

1166

Diabetic foot osteomyelitis can be successfully treated with antibiotics

S. Acharya;
Endocrinology and Diabetes, Lancashire Teaching Hospitals NHS Trust, Chorley, United Kingdom.

Background: Osteomyelitis (OM), a common complication of diabetic foot ulcer, is associated with higher risk of amputation. In our centre we treat OM primarily with antibiotics and we wanted to study the outcome of patient who had diagnosis of OM.
Aims of study: The aim of this study was to analyse clinical outcome of subjects who had diagnosis of OM in the past 5 years.
Subjects and methods: In this retrospective study, cases were selected from the electronic record with the diagnosis of OM. Results were crosschecked with radiology database. Pathology and microbiology database were also used to collect data.
Results: 147 cases had clinical diagnosis of OM out of which 130 (mean age 66.2±14.4 years and mean duration of diabetes 13.2±10.9 years) had diagnosis reconfirmed on at least one of the established criteria (Probe to bone 102, X-Ray changes 69, Bone scan 27, leukoscan 4 and bone biopsy 5). Of these reconfirmed cases, majority (66.9%) were male and had type 2 diabetes (80%) with mean HbA1c of 8.1± 2.1% and cholesterol of 4.2±1.5 mmol/L. Peripheral vascular disease, defined by absence of palpable pulses, was present in 61 (46.9%) subjects. Blood count performed on 112 cases showed raised neutrophil count (>7.5) only in 26 (23.2%). 64 had staphylococcus isolated from wound swab of which 20 (31.3%) had MRSA. Flucloxacillin and fusidate combination was used in 81 cases whereas ciprofloxacin and clindamycin combination was used only in 17 cases. 87 (66.9%) healed with single (n=46) or multiple (n=41) courses of antibiotics. 18 (13.8%) had amputation of which 16 (12.3%) were minor (Toes or Ray amputation) and 2 (1.5%) were major (above or below knee). 12 (9.2%) had vascular intervention (8 angioplasty & 4 bypass) and 8 (6.2%) died within 12 months of diagnosis due to other causes. There were no differences in outcome between subjects with or without x-ray changes. When compared between those which healed (n=87) and those patients who died or needed amputation (n=26), there was no difference in age sex, duration of diabetes, site of ulcer, presence of x-ray changes or peripheral vascular disease. OM due to MRSA was the only factor that predicted adverse outcome (21.1% vs 53.3%; p=0.04). Higher rate (p=0.01) of adverse outcome was noted in patients using combination of ciprofloxacin and clindamycin, which may be due to its use as a last resort in our clinic.
Discussion: Our data confirms that OM can be successfully treated with antibiotics. Flucloxacillin and fusidate can be used as first line treatment in majority of cases. Surgery should be reserved only for cases that fail to respond to medical treatment.

1167

Efficacy of moxifloxacin in the treatment of diabetic foot infections: results of the RELIEF study

N. Schaper[1], M. Dryden[2], P. Kujath[3], D. Nathwani[4], P. Arvis[5], P. Reimnitz[6], J. Alder[7], B. Hampel[8], I. Gyssens[9];
[1]University Medical Centre, Maastricht, Netherlands, [2]Royal Hampshire Hospital, Winchester, United Kingdom, [3]University Clinic of Luebeck, Germany, [4]Ninewells Hospital and Medical School, Dundee, United Kingdom, [5]Bayer Schering Pharma, Loos, France, [6]Bayer Schering Pharma AG, Wuppertal, Germany, [7]Bayer HealthCare, Montville, USA, [8]Bayer Schering Pharma AG, Berlin, Germany, [9]Radboud University Nijmegen Medical Centre, Netherlands.

Objectives: Diabetic foot infections (DFIs) cause substantial morbidity. As DFIs are usually polymicrobial, broad-spectrum antibiotics play an important

role in therapy. Due to their wide antimicrobial coverage and pharmacodynamic properties, fluoroquinolones, such as moxifloxacin (MXF), may have several advantages over other antimicrobial classes. The RELIEF study was conducted to provide further data on the efficacy of MXF in specific complicated skin and skin structure infections. Data on DFIs are presented here.
Methods: In this double-dummy, double-blind, randomised, controlled trial, patients with a DFI requiring antimicrobial therapy were stratified according to infection severity and the requirement for surgery. Patients received either IV/PO MXF 400 mg qd or IV piperacillin/tazobactam 4.0/0.5 g tds followed by PO amoxicillin/clavulanate 875/125 mg bd (PIP/TAZ-AMC), for 7-21 days. The DFI diagnosis was based on predetermined criteria, documented by repeated photographs and confirmed by an independent data review committee (DRC). The primary efficacy variable was resolution of infection 14-28 days after completion of study medication (test-of-cure, TOC) as determined by the DRC.
Results: A total of 206 patients (mean age 59.2 years) were valid for the efficacy analysis (MXF=110, PIP/TAZ-AMC=96). Of these, 65.5% of MXF- and 70.8% of PIP/TAZ-AMC-treated patients had clinical signs of peripheral arterial disease (ankle brachial index <0.9, foot pulses barely or non-palpable). Most patients had DFIs with a PEDIS score of 3, i.e. moderate in severity (MXF 81.3%; PIP/TAZ-AMC 86.2%). In the microbiologically-valid (MBV) population, polymicrobial infections were common (MXF: 60.9%; PIP/TAZ-AMC: 62.4%); the most frequently isolated pathogen was *S. aureus* (MXF 69.6%; PIP/TAZ-AMC 81.2%). Meticillin-resistant *S. aureus* was relatively uncommon in the MBV population (MXF 12.0%; PIP/TAZ-AMC 14.1%). A total of 150 (72.8%) patients had initial surgery (MXF 70.9%; PIP/TAZ-AMC 75.0%), including amputation in 46.4% (MXF) and 34.4% (PIP/TAZ-AMC) of PP patients. MXF and PIP/TAZ-AMC had similar efficacy with respect to clinical cure at TOC (Table). A total 20.9% MXF and 25.0% PIP/TAZ-AMC patients had additional surgeries >48 hours after the start of therapy and were assessed as clinical failures. Bacteriological success rates were comparable between treatment arms (Table).
Conclusion: IV/PO MXF had similar efficacy to IV PIP/TAZ-AMC in patients with DFI. MXF can be considered a valuable option for the treatment of moderate-to-severe DFI.

Table: Clinical and bacteriological success rates at TOC overall and by most commonly isolated pathogen

	MXF	PIP/TAZ-AMC	$P^{\ddagger}$ (95% CI)
	n/N (%)		
Clinical cure[§]	84/110 (76.4)	75/96 (78.1)	0.650 (-14.5, 9.0)
Bacteriological success (MBV population)			
Overall	66/92 (71.7)	61/85 (71.8)	0.658 (-16.9, 10.7)
Staphylococcus aureus Meticillin-susceptible Meticillin-resistant	 43/53 (81.1) 8/11 (72.7)	 39/57 (68.4) 10/12 (83.3)	 - -
Escherichia coli	6/8 (75.0)	6/9 (66.7)	-
Enterococcus faecalis	19/30 (63.3)	20/29 (69.0)	-

‡Cochran-Mantel-Haenszel test
§n/N=number of patients experiencing clinical cure/ total number of patients
n/N = number of patients experiencing eradication or presumed eradication/number of patients with pathogen isolated and an evaluable bacteriological response
CI: confidence interval; MBV: microbiologically valid population (all efficacy valid patients with a pathogen isolated at baseline)

The effect of topical phenytoin on healing in diabetic foot ulcers: a randomised controlled trial
J. Shaw[1], C.M. Hughes[2], K.M. Lagan[2], M.R. Stevenson[3], C.R. Irwin[4], P.M. Bell[5];
[1]Podiatry, Regional Centre for Endocrinology and Diabetes, [2]University of Ulster, [3]Department of Medical Statistics, Epidemiology and Public Health, Queen's University, [4]School of Dentistry, Queen's University, [5]Regional Centre for Endocrinology and Diabetes, Belfast, United Kingdom.

Background and aims: Phenytoin (PHT) may have a positive effect on wound healing by increasing collagen production and reducing bacterial load and wound exudate. A randomised, controlled, double-blind, clinical trial was conducted to evaluate the effect of topical PHT on healing in diabetic foot ulcers (DFU).
Materials and methods: A PHT dressing and a control dressing were manufactured. Participants of ≥ 18 years of age with peripheral neuropathy, stable vascular status, and a DFU ≥ 4 weeks duration were included. Participants with renal disease, acute ischaemia, necrosis, worsening infection or osteomyelitis were excluded. Subjects were independently randomised to either PHT or Control groups, received standard wound care, and dressing application. Primary end-point analysis (DFU closed or not at 16 weeks) was calculated by Survival Analysis. Analysis of secondary outcome (percentage change in DFU area over time) used an Ordinal Regression Model.
Results: Participants (n=65, 52 with Type 2 Diabetes) were randomised to the PHT (31) or Control group (34). Following a maximum of 16 weeks treatment, 60% of the DFUs closed overall (18 PHT: 20 Controls) with no statistically significant differences in complete healing or in DFU area over time between the two groups. Pain levels were reduced in the PHT-treated group. At 24 weeks, 1 DFU had recurred.
Conclusion: There were no differences in DFU closure rates or in DFU area over time between the two groups. This study does not support the use of PHT in the treatment of DFUs.

Improved survival in patients with diabetes and chronic foot ulcers after hyperbaric oxygen therapy. Outcome of a randomised double-blind placebo controlled study
M. Löndahl[1], P. Katzman[1], A. Nilsson[2], M. Landin-Olsson[1];
[1]Endocrinology, Clinical Sciences, Lund, [2]Internal Medicine, Ängelholm, Sweden.

Background and aims: Presence of diabetic chronic foot ulcers (DFU) is associated with an increased mortality risk. Hyperbaric Oxygen Therapy (HBOT) has been suggested as a treatment modality of DFU. HBOT increases oxygenation and stimulates angiogenesis. The aim of this study was to evaluate if HBOT improves survival in patients with diabetes and chronic foot ulcers.
Materials and methods: Hyperbaric Oxygen therapy in patients with Diabetes and chronic Foot Ulcers (HODFU) study is a prospective randomized double-blind placebo-controlled study evaluating the effect of 40 HBOT sessions as compared to 40 treatments with hyperbaric air (placebo). Patients receiving more than 35 treatment sessions were included in the predefined per-protocol analysis. Three-year mortality rates were evaluated in this study. Categorical variables were analyzed using Fischer´s exact test, continuous variables using Mann-Whitney U-test and Kaplan-Meier curves using Cox-Mantel test. A two-sided p-value <0.05 was taken as statistical significant.
Results: 75 patients (38 HBOT and 37 placebo) with a similar median age (67 and 71 years (n.s.) (HBOT and placebo)) and a diabetes duration of 22 and 21 years (n.s.) were included in this analysis. No differences were seen in comorbidity between groups. Mortality rates were 10.5 % and 29.7 % (p=0.04) respectively after three years follow-up. Median ages of deceased patients were 79 and 75 years (n.s.).
Conclusion: This study indicates that HBOT may improve survival in patients with diabetes and chronic foot ulcers.

Pathogenetic criteria of differentiation tactics at surgical treatment of purulent necrotic wounds in patients with diabetic foot
M.V. Svyrydov[1], N. Bondarenko[1,2], S. Bolgarska[2];
[1]Surgery, National Medical University, Donetsk, [2]Diabetology, State Institution "V.P. Komisarenko Institute of endocrinology and metabolism of the Academy of Medical Sciences", Kiev, Ukraine.

Background: A search for informative criteria for a wound process course in the treatment of destructive forms of Diabetic Foot Syndrome (DFS) presents a serious clinical problem, which requires new scientific approaches in its solution.
Aims: Development of prognostic criteria for a wound process course allowing choosing pathogenetically justified methods of surgical treatment of wounds in patients with DFS.

Material and methods: The results of a surgical treatment of 186 patients with destructive forms of DFS have been analyzed in accordance with PEDIS classification with $P_{1-2}E_{1-2}D_{2-3}I_{2-3}$ present. The condition of the intracellular tyrosinase system, the content of cytokines (IL-1β, IL-4, TNGα, IFNγ) and eicosanoids (PGE_2, LTB_4, PGI_2) in blood at different stages of the treatment have been studied. A wound coating, autoplasty, a tamponade by dermo-fat flap (DFF) and a culture of cultivated autofibroblasts have been used as means of covering postoperative wound defects, stabilization of a destructive process and acceleration of tissue reparation.
Results: The individual peculiarities of a wound process course were directly dependent on the area and depth of tissue destruction, power of the tyrosinase system, which finds its expression in the results of the tyrosinase index. After a surgical treatment of the wound, changes in the intercytokine coefficient allowed prognosing the course of a proliferation phase - 50% and higher increase of the coefficient was a favorable sign and an indication for the use of a wound coating or autoplasty. 10% decrease of the coefficient and lower appeared to be an unfavorable sign and required the use of a tamponade of a great wound defect by DFF and/or a culture of cultivated autofibroblasts with a further plastic covering of the wound. 14.3% decrease of the eicosanoid coefficient during 3-5 days after a necrosectomy was accompanied by a high efficiency of a wound coating and autoplasty application, quick wound healing. 33.5% and higher increase of the eicosanoid coefficient against the background of LTB_4 and PGI_2 deficiency testified to the humoral control disorder of inflammatory reparative processes which were accompanied by spread of a destructive process, a more prolonged period of wound healing and/or resulted in performing big amputations.
Conclusion: The reparation humoral regulators revealed reflect individual peculiarities of a wound process course and give an opportunity to make a prognosis concerning the outcome of wound healing in patients with DFS operated on.

1171

Outcome of surgical treatment in diabetic forefoot osteomyelitis
R. Da Ros, R. Assaloni, B. Brunato, S. Carlucci, C. Tortul;
Diabetologic Service, Monfalcone Hospital, Italy.

Background and aims: Osteomyelitis is one of the most frequent infections of the diabetic foot. The treatment of osteomyelitis of the foot in diabetic patients continues to be debated, most experts considered that the standard should be the surgical removal of infected bone. Aim of this study is to determine efficacy and relapse rate of surgical treatment of osteomyelitis.
Materials and methods: We performed a surgical removal of infected bone in 206 consecutives diabetic patients. Forefoot osteomyelitis were confirmed by probe to bone test and radiological signs of osteomyelitis.
Results: Osteomyelitis were localized in 140 patients at phalangeal level (68%), in remaining 66 patients at metatarsal head level: 19 first head (9%), 9 second head (4%), 5 third head (3%), 4 forth head (2%), 29 fifth head (14%). Bone culture was performed in 122 patients, in 118 patients was positive and Staphylococcus aureus was the organism isolated in majority of cultures (42%). Kind of surgical treatment: 152 conservative surgical procedures were performed (74%), in the remaining cases: 23 distal finger amputations , 20 finger amputations, 11 ray amputations. 154 patients (75%) healed, mean healing time was 62±42 days. Causes of healing failure were: 19 patients for ischemic relapse, 21 patients for residual osteomyelitis, 12 patients for other causes. 37 patients (18%) healed with a second surgical procedure. Once healed wound relapse was observed in only 5 patients (3%) in a mean follow up of 12±4 months.
Conclusion: Surgical removal of infected bone in forefoot osteomyelitis seem a safe procedure with an elevated healing rate and large possibility of conservative management. Relapse rate is low when healing is reached.

1172

Health Technology Assessment (HTA) on the importance of growth factors for the treatment of Diabetic Foot Ulcers (DFU)
B. Buchberger[1], M. Follmann[2], H. Huppertz[1], J. Wasem[1];
[1]University of Duisburg-Essen, Essen, [2]German Cancer Society, Berlin, Germany.

Background: Ulcers as a result of Diabetes mellitus are a serious problem with an enormous impact on the overall global disease burden due to the increasing prevalence of diabetes. Because of long hospital stays, rehabilitation, often required home care and the use of social services diabetic foot complications are costly. Therapy with growth factors could be an effective and innovative add-on to standard wound care. The aim of the HTA on behalf of the German Institute of Medical Documentation and Information DIMDI is to assess the safety and efficacy of growth factors alone or in combination with other technologies in the treatment of DFU including medical, economical, social, ethical and juridical aspects.
Methods: We systematically searched relevant data bases limited to English and German language and publications since 1990. Cost values were adjusted for the price level in 2008 and converted into Euro. Review and assessment of the quality of publications followed methods conforming to widely accepted standards for evidence-based medicine and health economics.
Results: We identified 25 studies (14 randomized controlled trials (RCT), nine cost-effectiveness analyses, two meta-analyses). The RCTs compared an add-on therapy to standard wound care with standard wound care/placebo alone or extracellular wound matrix: 6 studies used becaplermin, two rhEGF, one bFGF, and five studies the metabolically active skin grafts Dermagraft and Apligraf. Study duration ranged from 12 to 20 weeks and the study population comprised between 17 and 382 patients, average 130 patients. Treatment with becaplermin, rhEGF and growth factors secreting skin implants Dermagraft and Apligraf showed in eight out of 13 studies an advantage concerning complete wound closure and the time to complete wound healing with statistically significant differences. Evidence for a benefit of treatment with bFGF could not be found. In four out of the 14 studies the proportion of adverse events was 30 % per study group with no difference between the treatment groups. The methodological quality of the studies was affected by significant deficiencies. Economic evaluations showed becaplermin being cost-effective whereas no obvious statement can be made regarding Dermagraft and Apligraf because of diverging cost bases and incremental cost-effectiveness ratios.
Discussion: Differences in standard wound care are complicating the comparison of study results. Taking into consideration the small to very small sample sizes and other methodological flaws with high potential of bias the validity of the results with regard to effectiveness and cost-effectiveness has to be considered limited. The duration of treatment and follow-up examinations is not long enough to assess sustainability of intervention and surveillance of ulcer recurrences or potential treatment related adverse events like development of malignancy.
Conclusion: There are indications of an advantage for the add-on therapy with growth factors in DFU concerning complete wound closure and the time to complete wound healing. Further more studies of high methodological quality with adequate sample sizes and sufficient follow-up periods are necessary, also investigating patient-relevant parameters like health-related quality of life, acceptance and tolerance of intervention in addition to clinical outcomes.

PS 115 Retinopathy - prevalence and mechanisms

1173

Prevalence of diabetic retinopathy at first screening event in a national screening programme in Wales UK: 2005 - 2009

S. Roy Chowdhury[1], R.L. Thomas[1], S.D. Luzio[1], S.L. Hale[2], R.V. North[3], D.R. Owens[1];
[1]Diabetes Research Unit, Cardiff University, [2]Department of Ophthalmology, Cardiff and Vale University Health Board, [3]School of Optometry, Cardiff University, United Kingdom.

Background and aims: To report the prevalence of diabetic retinopathy (DR) in subjects with diabetes who attended for their first screening event with the Diabetic Retinopathy Screening Service for Wales (DRSSW) between 2005 and 2009.
Materials and methods: 135,152 subjects with diabetes (55.3% male, 42.6% female, 2.1% not documented) attended for their first screening event. Digital photography (2x 45° field of each eye) was performed following mydriasis with tropicamide 0.5%; retinal grading was based on the UK National Consensus Grading Protocol with the highest (worst) grade for either eye taken as the final grade. Referral to hospital eye services were made for those cases where the level of DR seen was pre-proliferative (PPDR) or proliferative (PDR) with or without the presence of maculopathy or maculopathy only i.e. referable diabetic retinopathy (RDR). The level of DR was considered to be of a sight-threatening level (STDR) if either or both PDR and maculopathy were present.
Results: 88,131 subjects (65.2%) had no DR and 47,021 (34.8 %) (57.5% male, 40.1% female, 1.5% not documented) had evidence of DR. In those subjects with DR at first screen the mean (±SD) age was 63.3 (14.8) years, duration of diabetes was 9.6 (9.0) years; 11.6% were T1DM, 64.9% T2DM and for 23.5% type not recorded. 13.9% of subjects were diet controlled, 42.2% received additional oral hypoglycaemic agents and 23.8% insulin. In 20.1% the treatment modality was not documented. During the five year screening period (Table 1) the prevalence of BDR at first screening remained essentially unchanged at approximately 80% of those patients with any evidence of DR. PDR increased from 0.9 to 2.6% over the 5 year period but maculopathy remained essentially unchanged between 4.4-5.1%. The number of people requiring referral to ophthalmologists increased slightly following the first year but then remained unchanged.
Conclusion: In a national screening programme at first screen 65.2 % of patients had no DR. Of those with DR (34.8 %) the majority had BDR (~80%) which did not require referral to the hospital eye service. In summary only 5.6% of the total population at first screen required further assessment at the hospital eye service.

Table 1 Presence of DR at first screen (2005 - 2009)

	All Years		2005	2006	2007	2008	2009
	N	%	%	%	%	%	%
BDR	36,724	78.1	80.8	76.5	77.6	76.5	76.7
PPDR	2,490	5.3	4.9	5.6	5.6	5.1	5.3
PDR	736	1.6	0.9	1.4	1.7	2.5	2.6
Maculopathy	2,222	4.7	4.4	5.1	4.8	4.6	4.6

Prevalence and associated risk indicators of retinopathy in rural Bangladeshi population with and without diabetes

A. Akhter[1], K. Fatema[1], A. Afroz[1], S.M.A. Hannan Miah[2], A.S.M. Nurullah Awal[3], A. Raihan[3], L. Ali[4], A. Hussain[5];
[1]Dept of Epidemiology & Biostatistics, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh, [2]Dept of Ophthalmology, Thakurgaon Swasthoseba Hospital, Thakurgaon, Bangladesh, [3]ORBIS International, Dhaka, Bangladesh, [4]Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh, [5]Dept of International Health, University of Oslo, Norway.

Background and aims: Retinopathy, a potential sight threatening condition, is a significant public health problem. The absence of reliable population based epidemiological data on retinopathy in Bangladesh is a serious impediment to the effective national planning of eye care programmes. In the above context, we planned to carry out an epidemiological study to create a baseline data focused on retinopathy. We aimed to observe the prevalence of retinopathy among people with normal and abnormal glucose metabolism in a remote rural community of Northern Bangladesh and to identify the associated risk indicators for developing retinopathy in this population.
Materials and methods: This population based cross-sectional study was conducted through screening in camp settings, which included a total of 836 participants (468 male, 368 female), aged at or above 25 years. Retinopathy was determined by ophthalmoscope and fundus photography. Anthropometric measurements (BMI and WHR), OGTT, glycosylated haemoglobin (HbA_1c), blood pressure, lipid profile, serum creatinine and urine albumin-creatinine ratio (UACR) were also observed. Serum glucose (fasting and 2 hr after 75 gm glucose) was measured by glucose oxidase method, HbA_1c by high performance liquid chromatography (HPLC), total cholesterol, triglyceride and HDL were analyzed by enzymatic-colorimetric method, LDL was estimated by Friedewald's formula, serum creatinine and urine creatinine were measured by alkaline picrate method and urine albumin by pyrogallol red method. Logistic regression analysis was used with adjustment for potential confounders.
Results: The overall prevalence rate of retinopathy was 5.4% (95% CI 3.9-6.9). Moreover, the prevalence of retinopathy among the diabetic, prediabetic and nondiabetic subjects were 21.6% (95% CI 11.2-32.0), 13% (95% CI 3.4-22.6) and 3.5% (95% CI 2.2-4.8), respectively. Females (6.0%) had higher prevalence of retinopathy compared to males (4.9%). The peak prevalance of retinopathy (10.7%) was found in the older age group (above 55 years). Age, BMI, WHR, blood pressure, serum glucose (fasting and 2 hr after 75 gm glucose), HbA1c, triglyceride, total cholesterol, LDL-cholesterol, serum creatinine and UACR were significantly ($p<0.05$) higher among the subjects with retinopathy compared to those without retinopathy. The retinopathy subjects with abnormal glucose metabolism had significantly ($p<0.05$) higher BMI, blood pressure, triglyceride, total cholesterol, LDL-cholesterol, serum creatinine and UACR compared to retinopathy subjects with normal glucose metabolism. On logistic regression analysis age, BMI, abnormal glucose metabolism, hypertension and UACR were found as significant independent risk indicators for the occurrence of retinopathy in this population.
Conclusion: The data suggest that, in addition to serum glucose control in diabetic patients, screening for hypertension, general obesity, and proteinuria as well as adequate treatment of these risk indicators may prevent retinopathy in rural Bangladeshi population.

Early-onset type 2 diabetes: high risk for premature significant diabetic retinopathy

S.H. Song, C.A. Hardisty;
Diabetes Centre, Northern General Hospital, Sheffield, United Kingdom.

Background and aims: The incidence of early onset (age of diagnosis <40) type 2 diabetes (T2D) is increasing. Given the potential long duration of exposure to the deleterious diabetic milieu, this cohort is at risk of developing premature diabetes complications. Diabetic retinopathy is a significant cause of morbidity in T2D and at present, the impact of early age of diabetes onset on the burden, severity and prematurity of retinopathy complication remains unclear.
Materials and methods: A cross-sectional study using hospital diabetes register and eye screening database to identify T2D subjects and quantify se-

verity of diabetic retinopathy. Early and later onset is defined as age of T2D diagnosis below and above 40 years respectively. Severity of retinopathy is classified into background, pre-proliferative, proliferative and maculopathy. Significant retinopathy (SigR) refers to pre-proliferative, proliferative or maculopathy. Prevalence and severity of retinopathy was analysed at diabetes durations of <10, 10-20 and >20 yrs.
Results: 2516 T2D subjects were identified of whom 455 were diagnosed below age 40 yrs. Mean age of diagnosis for early and later onset cohort was 32.2 and 54.6 yrs respectively. Despite the short diabetes duration (early vs later; 6.2 vs 6.4 yrs, p=NS), early-onset T2D subjects with mean age of 38.4 yrs had substantial burden of retinopathy of all severity (26.9%), similar to later-onset cohort (29.5%) with mean age of 62.4 yrs. Prevalence of retinopathy of all severity increased with diabetes duration (p<0.05) in both cohort. Diabetes duration was a significant predictor of retinopathy complications (p<0.05). The prevalence of SigR increased substantially after 10 yrs of diabetes with both early and later onset cohort experienced similar complication burden (duration <10 yrs: early vs later; 5.7 vs 8.2%, p=NS; duration 10-20 yrs: early vs later; 26.6 vs 24.3%, p=NS; duration >20 yrs: early vs later, 45.5 vs 38.5%, p=NS) which occurred approximately 15-25 years earlier among early-onset cohort (mean age - duration <10 yrs: early vs later; 38.4 vs 62.4 yrs, p<0.05; duration 10-20 yrs: early vs later; 46.5 vs 68.6 yrs, p<0.05 and duration >20 yrs: early vs later; 58.4 vs 73.8 yrs, p<0.05). Early-onset cohort were more likely to have suboptimal glycaemic control (HbA1c >7.5%) than later-onset cohort irrespective of diabetes duration (duration <10 yrs: early vs later; 67.5 vs 58.6%, p<0.05; duration 10-20 yrs: early vs later; 82.6 vs 67.5%, p<0.005; duration >20: early vs later; 81.0 vs 71.1%, p<0.05).
Conclusion: Early onset T2D subjects have substantial risk of developing sight-threatening eye disease in later years but at an earlier age than later onset cohort. Important contributing factors include suboptimal diabetes control and prolonged exposure to diabetic milieu.

1176

Glycated haemoglobin as a surrogate marker for the appearance and progression of retinopathy in type 2 diabetes mellitus: systematic review and meta-analysis

P. Rys[1], A. Wieczorek[1], A. Marcisz[1], I. Skrzekowska-Baran[2], M.T. Malecki[3];
[1]HTA Consulting, Krakow, [2]NovoNordisk, Warsaw, [3]Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland.

Background and aims: Glycated hemoglobin (HbA1c) is commonly employed in clinical trials as a surrogate marker of diabetes control and the risk for diabetic complications in type 2 diabetes mellitus (T2DM). To date, several trials have examined the relationship between HbA1c and microvascular complications, but no systematic review (SR) has been published. We performed a SR and meta-analysis to examine the association between HbA1c and the appearance and progression of diabetic retinopathy (DR) in T2DM.
Materials and methods: We conducted a systematic literature search in electronic medical databases (MEDLINE, CENTRAL) with highly sensitive search strategy, including over 100 terms grouped into three categories: population (e.g. "diabetes mellitus", "non insulin dependent diabetes mellitus"); surrogate (e.g. "glycosylated hemoglobin") and clinically outcomes (e.g. "retinopathy"). Observational studies (OS) and randomized, controlled trials (RCT) of retinopathy in T2DM patients that reported HbA1c level were included. Estimates were made of the adjusted relative risk (RR) of complications for an increase in HbA1c of 1%. Weighted mean differences (WMD) in HbA1c level between the case (with DR) and the control group (without DR) were also calculated. Meta-regression was used to explain heterogeneity between the studies with respect to the risk of DR. The following covariates were considered: follow-up, HbA1c level, age, disease duration, BMI, cholesterol level and blood pressure.
Results: We identified 17 trials that fulfilled the inclusion criteria, involving a total of 10 236 patients. Based on two RCT (n = 240), pooled RR for incidence of DR was calculated as 1.57 (confidence interval [CI]: 1.21-2.03; p < 0.001) for an increase in HbA1c of 1%. Meta-analysis of OS confirmed the results from RCT (RR = 1,61; CI95% [1.29-2.01]; p < 0.001). Pooled data from 5 RCT (n = 514) showed that RR of the incidence or progression of DR was 1.48 (CI95% [1.04-2.10]; p < 0.029) for an HbA1c increase of 1%. The cumulative results of five OS were similar (RR = 1,50, CI95% [1.28-1.77]; p < 0.0001. Based on data from RCTs and OS there were no significant correlation between incidence of proliferative DR and increase of HbA1c of 1%. Data from one RCT demonstrated that increase in HbA1c level of 1% increased the risk of blindness (RR = 6.20, CI95% [0.95-40.61]; p = 0.057), but this but was of borderline statistical significance. A meta-analysis of two OS (n = 238) demonstrated a lower mean HbA1c level in patients without DR compared with patients with DR (WMD = 0.43, 95%CI [0.15-0.72]; p = 0.003). Pooled results of 5 OS (n = 1874) revealed that HbA1c was significantly lower in the group without progression of DR than in the group with DR progression (WMD = 0.74, 95%CI [0.39-1.08]; p < 0.001). In meta-regression HbA1c explained the heterogeneity in 65.4%. The directional coefficient was statistically significant and equals 0.58, which means that increase HbA1c level by 1% results in increase the risk of DR by 1.79 times (CI95% [1.28-2.51]; p = 0.003). The impact of other covariates on heterogeneity between trials was small and statistically insignificant.
Conclusion: The results of our SR indicate a significant correlation between HbA1c level, and appearance and progression of DR in T2DM. Thus, HbA1c may be considered an appropriate surrogate endpoint for DR in T2DM.

High glucose alters mitochondrial morphology and membrane potential heterogeneity in retinal pericytes

K. Trudeau, A. Molina, S. Roy;
Medicine and Ophthalmology, Boston University School of Medicine, Boston, USA.

Background and aims: Mitochondrial dysfunction is known to play a role in retinal vascular cell loss, which is a prominent lesion of diabetic retinopathy. We have previously reported that high glucose (HG) induces mitochondrial fragmentation and membrane potential heterogeneity in retinal endothelial cells, which contributes to cytochrome c release and apoptosis. Thus, we sought to determine the effects of HG on mitochondrial morphology and membrane potential heterogeneity in retinal pericytes.
Materials and methods: Bovine retinal pericytes (BRPs) were grown in normal (5mM) or HG (30mM) medium for 6 days. Both sets of cells were double-stained with MitoTracker Green FM (MTG, 125nM) and tetramethylrhodamine-ethyl-ester-perchlorate (TMRE, 8nM) and imaged using confocal microscopy. Images were analyzed for average mitochondria shape within a cell using Form Factor (FF) and Aspect Ratio (AR) values of the mitochondria. FF value of 1 corresponds to a circular, un-branched mitochondrion, and higher FF values indicate a longer, more-branched mitochondrion. AR of 1 corresponds to a circular mitochondrion, and higher AR values indicate more elliptical mitochondrion. The images were also analyzed for heterogeneity of mitochondrial membrane potential within a cell, using deviation of fluorescence intensity (FI) values for the ratio of red (TMRE) to green (MTG) dye for several mitochondria within each cell.
Results: BRPs grown in HG media exhibited significant fragmentation of mitochondria compared to BRPs grown in normal media (FF for HG: 1.85 compared to 2.51 in normal, p=0.004, AR for HG: 2.32 compared to 2.80 in normal, p=0.009). Simultaneously, the BRPs grown in HG showed greater heterogeneity of mitochondrial membrane potential compared to normal BRPs (FI deviation for HG: 224 ± 78% of normal, p<0.001).
Conclusion: Under HG condition, mitochondria of retinal pericytes display significant fragmentation and membrane potential heterogeneity. The observed mitochondrial fragmentation and increased membrane potential heterogeneity in HG could play a role in the accelerated apoptosis associated with the retinal pericytes in diabetic retinopathy.

Enhanced thrombin formation, platelet activation in patients with diabetic retinopathy

P. Yu, D. Yu;
Department of Nephropathy & dialysis, University of Tianjin Medicine, Metabolic Disease Hospital, China.

Background and aims: Diabetic retinopathy (DR) is the commonest microvascular complication of diabetes, and remains one of the leading causes of blindness worldwide. Postulated mechanisms of this observation include prothrombotic effects. The aim of the study was to evaluate potential prothrombotic alterations in diabetic retinopathy patients in relation to hyperglycemia, including thrombin formation, platelet activation, and fibrin network structure/function.
Materials and methods: The participants were 120 healthy subjects and 150 diabetic patients. We excluded patients with nephropathy, cardiovascular dis-

ease, and clotting disorder. On the basis of the fundus photography, the participants were divided into four groups, including normal individuals (n=120), diabetes mellitus (DM) (n=45), DM with non-proliferative DR(NPDR) (n=60), and DM with proliferative DR(PDR)(n=45). The lipid profile, C-reactive protein (CRP), glucose, insulin, platelet count, prothrombin time (PT), activated partial thromboplastin time (aPTT), D-dimmer and Fibrinogen were determined using routine laboratory methods. We determined generation of thrombin-antithrombin complexes (TATs) and soluble CD40 ligand (sCD40L), a platelet activation marker, at the site of microvascular injury, together with ex vivo plasma fibrin clot permeability and lysis time.
Results: The DR patients had increased maximum rates of formation and total production of TATs (by 52.9%, P <0.01, and by 22.5%, P <0.01, respectively) as well as sCD40L release (by 19.2%, P<0.01, and by 18.3%, P<0.01, respectively) compared with those with hyperglycemia, whereas PDR patients had the highest values of TATs and sCD40L variables (P < 0.01 for all comparisons). Patients with DR had longer clot lysis time (by 21%, P<0.01) similar to that in diabetic subjects, but not lower clot permeability compared with that in normoglycemic subjects. PT and aPTT were similar for all the four groups; however, their corresponding fibrinogen levels were significantly different between PDR group and controls (4.55 ±2.12g/L vs. 3.06±1.25g/L, P<0.05). There was no difference in fibrinogen levels between NPDR group, DM group and control group.
Conclusion: Diabetic patients, with retinopathy especially with proliferative retinopathy, are associated with enhanced local thrombin generation and platelet activation, as well as unfavorably altered clot features. Our results suggested that prothrombotic alterations in diabetic patients might be implicated in the pathogenesis of diabetic retinopathy.

Retinopathy modulates taurine transporter expression in peripheral mononuclear blood cells of type 2 diabetic patients
G. Seghieri[1], R. Anichini[1], A. De Bellis[1], A. Berti[1], L. Bianchi[2], Z. Napoli[2], L. Della Corte[3], F. Franconi[4];
[1]Dpt. of Internal Medicine, Spedali Riuniti, Pistoia, [2]Dpt. of Clinical Chemistry, Spedali Riuniti, Pistoia, [3]Dpt. of Pharmacology, University of Florence, [4]Dpt. of Pharmacology, University of Sassari, Italy.

Background and aims: Taurine, a semi-essential aminoacid which acts as an antioxidant, cell osmolyte, and modulator of trans-membrane calcium and glucose metabolism, is more concentrated (about 10^3-fold) in the intracellular compartment than in the extra-cellular milieu due to the action of a specific Na-dependent amino acid-transporter namely the taurine transporter (TauT), whose expression has so far been either morphologically and functionally well characterized. TauT is well represented in retinal epithelial cells where is acutely down regulated by high glucose concentrations *'in vitro'*. At the same time taurine appears to be very important in the retinal function besides its known role as modulator of glucose metabolism. However since no study has ever investigated the relationship between TauT expression and diabetes, we conceived this preliminary study to test *'in vivo'* whether TauT expression is modified in blood mononuclear peripheral cells (MPC) of patients with type 2 diabetes with or without micro/macrovascular complications.
Materials and methods: We measured plasma taurine by HPLC and TauT gene expression by real-time PCR analysis in MPC of 74 type 2 diabetic patients with or without micro/macro-vascular complications and in 44 age-and-sex matched controls. In diabetic patients, presence of retinopathy, nephropathy, neuropathy and cardiovascular disease was ascertained by appropriate clinical and instrumental investigations.
Results: Median value [interquartile range] of TauT expression, represented as arbitrary units (AU), was significantly higher in diabetic patients than in age-and-sex matched controls (2.08 [2.42]AU *vs*. 1.07 [2.68]AU; p=0.009) and was weakly related to HbA1c (r=0.29; p=0.001). As compared with uncomplicated individuals a trend toward decreased TauT expression was observed in patients with macroangioapthy (n=16; 1.16 [1.55]AU *vs* 2.24 [2.23]AU), peripheral neuropathy (n=17; 1.71[0.96]AU *vs* 2.16 [2.10]AU) or persistent micro/macroalbuminuria (n=21; 2.06 [2.35]AU *vs* 2.30 [4.20]AU; p>0.05 in all cases). Patients with retinopathy (n=23) had a significantly lower TauT expression than those who were unaffected, exhibiting a median value similar to the value of controls (1.159 [1.554]AU *vs*. 2.240 [2.226]AU; p=0.006). There was no difference in median plasma taurine levels between controls and diabetics, either with or without retinopathy (29.6 [15]µmol/l *vs.* 28.9 [17.2]µmol/l).
Conclusion: TauT gene expression in MPC is modified by type 2 diabetes, being significantly increased in patients without retinopathy, hypothesising its possible selective protective role against the development of this microvascular complication.

Immunoexpression of the vascular endothelial growth factor and its receptors in diabetic lens
D.V. Lipatov, A.G. Kuzmin, A.U. Abrosimov, O.M. Smirnova, M.V. Shestakova;
Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims: The diabetic cataract is one of the causes of blindness among diabetic patients. There are many different factors leading to the cataract formation. It is known that cataract appears earlier in diabetic patients than in general population and has several morphological features. Excessive glucose oxidation, polyol pathway, hyperosmolarity, deposition of advanced glycation end products in the lens and damage of its matrix are shown to lead to lens opacity in diabetic patients. The aim of the study was to indentify the vascular endothelial growth factor (VEGF) and its receptors 1 and 2 types (VEGF-R_1 and VEGF-R_2 respectively) in lens tissue after cataract surgery carried put in diabetic patients.
Materials and methods: 10 extracted diabetic lenses were studied. The mean age of included patients was 69,9±7,69 years, all patients had type 1 and type 2 diabetes mellitus, almost all patients were treated with insulin. For the immunohistochemical staining the paraffin-embedded tissue sections (4 µm) of the formalin-fixed lenses were prepared. Before staining the slides were deparaffinized and rehydrated. The 20 min heat-induced epitope retrieval was done (for VEGF determining - with DakoCytomation Target Retrieval Solution, Ph9; for VEGF-R_1 and VEGF-R_2 - with Citrate buffer, Ph6). The sections were incubating in 10% hydrogen peroxide for 20 min to blocking the endogenous peroxidase activity. The primary anti-VEGF (monoclonal mouse anti-human VEGF, clone VG1, "DAKO") was using at a dilution range of 1:50 and applied on sections using 30 min incubation at room temperature. The primary anti-VEGF-R_1 and anti-VEGF-R_2 (rabbit polyclonal anti-VEGF Receptor 1 and rabbit polyclonal anti-VEGF receptor-2 respectively, "Novus biologicals") were using at a dilution range of 1:50 and applied on sections using 60 min incubation at 36,6°C. The colored end product were developed by using the universal secondary antibodies, detection system "EnVision", "DAKO", and following incubation with 3,3'-diaminobenzidine for 5 min in dark place.
Results: We observed immunoexpression of VEGF only in 2 of 10 diabetic cataracts on the cytoplasmic membrane of the lens fibers. There wasn't found the immunoexpression of VEGF-R_1 in lens sections. But in all lenses the VEGF-R_2 was found both on the cortical subcapsular lens fibers and lens epithelium cells. The immunoexpression was strong and higher in the superficial subcapsular lens fibers.
Conclusion: VEGF is known as the necessary factor for normal growth and development of the eye. For example, it supplies metabolic effect to the retinal pigment epithelium and also is detected in normal lens during ontogenesis. In diabetic patients the lens opacification develops earlier than among nondiabetic population. Our investigation may explain the intensive cataract formation and cortical localization of lens opacity due to the metabolic and proliferative effects of VEGF to lens epithelium via its receptor VEGF-R_2. Activation of VEGF-R_2 in lens epithelium and subcapsular lens fibers may cause excessive permeability and proliferation of lens epithelium and lead to the lens opacity.

PS 116 Retinopathy - new screening tools

Characterising the development of diabetic retinopathy in the Diabetes Care System West-Friesland, the Netherlands

H. Zavrelova[1], T. Hoekstra[2,3], M. Alssema[2], L.M.C. Welschen[4], G. Nijpels[4], A.C. Moll[1], B.C.P. Polak[1], J.M. Dekker[2];
[1]Ophthalmology, , [2]The EMGO Institute for Health and Care Research, [3]Health Sciences, [4]General Practice, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: The development and progression of diabetic retinopathy is known to be influenced by risk factors such as HbA1c, blood pressure and lifestyle variables. It is also known that the pace at which diabetic retinopathy develops, progresses or regresses is heterogeneous. Firstly, we therefore identified distinct developmental patterns of diabetic retinopathy; secondly, we assessed the patient characteristics of these patterns.
Materials and methods: A cohort of type 2 diabetes patients participating in the Diabetes Care System in West-Friesland, The Netherlands was followed for 2 to 8 years, between 1998 and 2005. The first visit was considered baseline. Annually, risk factors were measured and 2-field fundus photographs were taken with a non-mydriatic camera and graded according to EURODIAB. Latent Class Growth Analyses were used to identify distinct developmental patterns of diabetic retinopathy. Baseline characteristics of these patterns were assess with ANOVA with post hoc Bonferroni corrections and Chi-square tests or with a Kurskal Wallis test in case of skewed distribution.
Results: A total of 3392 patients were included in the study. Five clusters of patients with distinct developmental patterns of diabetic retinopathy were identified: A) patients without any signs of diabetic retinopathy, B) patients with fluctuating background diabetic retinopathy, C) patients with mild background diabetic retinopathy progressing to preproliferative diabetic retinopathy, D) patients with severe non-proliferative diabetic retinopathy progressing to (pre)proliferative diabetic retinopathy, and E) patients with persistent proliferative diabetic retinopathy. Risk factors characterizing the various patterns are shown in Table 1. Results show cluster A as the largest cluster characterized by low fasting plasma glucose levels and HbA1c and a short diabetes duration.
Conclusion: Identification of different developmental patterns of diabetic retinopathy is possible and might help understand the influence of certain risk factors on the course of diabetic retinopathy in individual diabetes patients.

Table 1. Selected baseline characteristics of five distinct developmental patterns of diabetic retinopathy (mean ± sd or median (interquartile range)).

	Cluster A (n=2955)	Cluster B (n=297)	Cluster C (n=71)	Cluster D (n=41)	Cluster E (n=28)	P < 0.05 between clusters:
Albumin-creatinine Ratio	3.2 ± 14.0	5.5 ± 17.9	6.4 ± 19.5	9.7 ± 25.1	11.2 ± 22.3	A vs. E
HDL cholesterol (mmol/l)	1.19 ± 0.32	1.20 ± 0.32	1.35 ± 0.81	1.13 ± 0.31	1.26 ± 0.35	C vs. A/B/D
Fasting plasma glucose (mmol/l)	8.8 ± 3.4	9.8 ± 3.1	9.9 ± 2.8	10.9 ± 3.6	10.7 ± 4.2	A vs. B/D/E
BMI (kg/m$^{2)}$	30.1 ± 5.3	28.8 ± 4.8	29.3 ± 4.6	30.7 ± 5.7	31.6 ± 5.6	A vs. B
Systolic blood pressure (mmHg)	142 ± 21	145 ± 22	149 ± 24	143 ± 26	149 ± 22	A vs. C
HbA1c (%)	7.6 ± 1.8	8.1 ± 1.9	8.1 ± 1.6	9.5 ± 2.1	9.0 ± 1.8	A vs. B/D/E D vs. B/C
Diabetes duration (years)	2 (1 - 5)	5 (1 - 9)	6 (3 - 12.5)	10 (4.5 -14)	13 (7.5 - 24.5)	P < 0.001

Information technology to control screening for diabetic retinopathy

A. Gudmundsdottir[1], E. Stefansson[1], E. Olafsdottir[1], T. Aspelund[2], O. Palsson[3], O. Thorisdottir[4], T. Bek[4];
[1]Landspitali, Reykjavik, Iceland, [2]University of Iceland, Reykjavik, Iceland, [3]Risk Medical Solutions, Reykjavik, Iceland, [4]Aarhus University, Denmark.

Background and aims: Annual screening for diabetic eye disease is effective, but may be too frequent and costly for low risk patients. The aim of the study is to use computer based individual risk assessment to make diabetic eye screening programs less expensive and safer.
Materials and methods: We used epidemiological data to create a mathematical algorithm, which calculates individual risk of sight threatening retinopathy. The individual´s risk level is then used to determine his/her screening interval. The algorithm was tested against the diabetes database in Århus, Denmark (5210 patients, 20 years).
Results: In the diabetes database the algorithm (set at risk margin 4%) suggested an average screening interval of 27 months, with a range of 6 to 60 months. 95 patients progressed to sight threatening retinopathy within the recommended screening interval. At risk margin 2% the respective numbers are 17 months and 32 patients. In comparison, with the standard 12 month screening program 149 patients progressed to sight threatening retinopathy within the recommended screening interval. Our algorithm, at risk margin 4%, increases safety by 36% while reducing cost of diabetic screening programs by 55% as compared to yearly screening exams. At 2% risk margin increased safety was 79% and cost reduction 30%.
Conclusion: The use of information technology based on epidemiological data allows individual risk assessment, standardization of risk and an individualized determination of screening intervals. The reduction in screening visits decreases cost of diabetic screening programs by more than 50% compared to programs with yearly screening exams.

Genomic and proteomic characterisation of non-proliferative retinopathy in a mouse model

A. Ribera[1,2], P. Villacampa[1,2], V. Haurigot[1,2], C.J. Mann[1,2], F. Bosch[1,2];
[1]CBATEG and Department of Biochemistry and Molecular Biology, School of Veterinary Medicine, Universitat Autonoma de Barcelona, [2]CIBER of Diabetes and Associated Metabolic Disorders, Barcelona, Spain.

Background and aims: Diabetic retinopathy is the leading cause of loss of visual acuity and blindness in adulthood. Transgenic mice overexpressing Insulin-like Growth Factor (IGF-I) in the retina have retinal alterations characteristic of non-proliferative retinopathy and, with age, mice develop alterations that mimic the proliferative stage of diabetic retinopathy such as neovascularization in the vitreous cavity and retinal neovascularisation. The aim of this study was to perform genomic and proteomic analyses in IGF-I transgenic retinas to identify key molecular markers in early developmental stages of the pathology.
Materials and methods: Retinas from 4 month-old transgenic and wild-type animals were collected, homogenised and total RNA and protein extracts were obtained. We compared gene expression profiles in transgenic and wild-type retinas with microarrays and confirmed the expression of selected genes by RT-PCR. Retinal protein extracts were separated by bidimensional electrophoresis and protein spots were identified using mass-spectrometry.
Results: Gene profile analysis detected 37 genes differentially expressed, 25 of which were up-regulated and 12 genes were down-regulated more than 1.5-fold in transgenic retinas compared with wild-type. Most of the up-regulated genes were classified in three categories: gliosis, retinal stress and angiogenesis, whereas down-regulated genes were related with CNS development and angiogenesis. By RT-PCR we found that transgenic retinas already overexpressed gliosis-related genes (Gfap, S100b, Gja) at an early age (1.5 months old), when transgenic mice neither presented morphological nor biochemical alterations.This overexpression was maintained or even increased in transgenic animals with time. The same pattern was observed with retinal-stress-related genes such as Nupr1, Lcn2 and Edn2. Proteomic studies showed 37 proteins differentially produced in transgenic retinas relative to wild-type, 18 of which were increased, with 19 were decreased. The majority of the identified proteins contribute to metabolic processes.
Conclusion: Most of the alterations found in gene profile analysis in transgenic retinas have also been reported in retinas from diabetic rats and in

human diabetic retinas, suggesting that the activation of glial and stress-response genes play a key role in initiating the pathology. Overall, these results also validate the IGF-I transgenic mouse model as an excellent tool to find therapeutic targets for early stages of retinopathy and to assay new therapies.

1184

Metabolic fingerprints of proliferative diabetic retinopathy. An ^{1}H NMR-based metabonomic approach using vitreous humor

R. Simó[1], I. Barba[2], C. Hernández[1], M.A. Alonso[3], L. Masmiquel[4], D. García-Dorado[2], M. Garcia-Ramírez[1];
[1]Diabetes Research Unit and CIBERDEM, Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, [2]Laboratory of Experimental Cardiology and RECAVA, Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, [3]Ophthalmology Department, Hospital Son Llàtzer, Palma, [4]Endocrinology Department, Hospital Son Llàtzer, Palma, Spain.

Background and aims: To explore the metabolic profile of vitreous fluid from patients with proliferative diabetic retinopathy (PDR) using ^{1}H NMR based metabonomic analysis.
Material and methods: Vitreous samples from 22 type 1 diabetic patients with PDR and 22 vitreous samples from non-diabetic patients with macular hole (MH) (control group), closely matched in terms of age (46·1±9·2 vs. 45·3±11·5 years) were selected from our vitreous bank. The exclusion criteria were as follows: 1) previous vitreoretinal surgery; 2) photocoagulation in the preceding 6 months; 3) recent vitreous hemorrhage (less than 3 months before vitrectomy), macroscopic hemovitreous or intravitreous hemoglobin >5 mg/ml; 4) history of glaucoma; 5) renal failure (plasma creatinine ≥ 120 μmol/l); and 6) other chronic diseases apart from diabetes. ^{1}H NMR spectra were acquired on a 400 MHz (9·4 T) magnet interfaced to a Bruker Avance 400 spectrometer (Bruker, Rheinstetten, Germany). Data analysis included a principal component analysis (PCA) and partial least squares discriminant analysis (PLS-DA). In addition, ^{1}H-^{1}H and ^{1}H-^{13}C HMQC (Heteronuclear Multiple Quantum Coherence) correlation spectra were acquired for the identification of metabolites. Furthermore, the main metabolites accounting for the differences in metabolic profile were also assessed by current biochemical methods.
Results: Lactate was the most abundant metabolite and it was higher in samples from PDR patients than non-diabetic patients (p=0.02). Glucose was significantly higher in samples from PDR patients than non-diabetic patients (p=0.03). After removing the lactate peak at 1.35 ppm, and using PLS-DA, a model was obtained which was able to correctly classify 19 out of 22 patients with PDR and 18 out of 22 controls, resulting in a sensitivity of 86% and a specificity of 81%. The main metabolites involved in this specific pattern recognition were galactitiol and ascorbic acid (AA), and they were significantly lower in PDR patients.
Conclusion: ^{1}H NMR based metabonomic analysis of vitreous fluid permits to obtain a metabolic signature of PDR. Apart from the higher abundance of lactate and glucose, significant deficits of galactitiol and AA are the main metabolic fingerprints of vitreous fluid from PDR patients.

Identification of new pathogenic candidates for diabetic macular oedema using fluorescence-based difference gel electrophoresis (DIGE) analysis

M. Villarroel[1], M. Garcia-Ramírez[1], C. Hernández[1], N. Colomé[2], L. Corraliza[1], L. García-Pascual[3], J. Casado[4], F. Canals[2], R. Simó[1];
[1]Diabetes Research Unit and CIBERDEM, Institut de Recerca Hospital Universitari Vall d'Hebron, [2]Proteomics Laboratory, Vall d'Hebron Institute of Oncology, [3]Endocrinology Department, Hospital Mútua de Terrassa, [4]Ophthalmology Department, Hospital Mútua de Terrassa, Barcelona, Spain.

Background and aims: Diabetic macular edema (DME) is the main cause of visual impairment in diabetic patients. The aim of the present study was to explore the differential proteomic pattern of the vitreous fluid from DME patients by means of fluorescence-based difference gel electrophoresis (DIGE).
Material and methods: Samples of vitreous from 8 type 2 diabetic patients (4 with DME without proliferative diabetic retinopathy [PDR] and 4 with PDR without DME), and 8 from non-diabetic subjects with idiopathic macular hole (control group) were selected from our vitreous bank for proteomic analysis. To further confirm the potential candidates identified by DIGE eighteen additional samples (6 PDR, 6 DME and 6 MH, matched by age) were analyzed by ELISA. Exclusion criteria included photocoagulation during the preceding 6 months and recent vitreous hemorrhage or intravitreous hemoglobin higher than 5 mg/ml.
Results: Selecting an abundance ratio of 1.5-fold, p<0.05, as the threshold for the study, 4 proteins were specifically associated with DME. Hemopexin was significantly higher in the vitreous fluid of patients with DME in comparison with both control subjects and PDR patients. By contrast, clusterin, transthyretin and crystalline S were significantly decreased in the vitreous of patients with DME. The differential production of hemopexin, clusterin and transthyretin was further confirmed by ELISA. In view of the current information, hemopexin and clusterin seems to be more directly related to the development of DME. Hemopexin is the best-characterized permeability factor in steroid-sensitive nephrotic sindrome (SSNS). T-cell-associated cytokines like tumor necrosis factor-alpha (TNF-alpha) are able to enhance hemopexin production in mesangial cells in vitro and this effect is prevented by corticosteroids. It should be noted that proinflammatory cytokines have been involved in the development of DME and, therefore, hemopexin might be a mediator of the disruption of the blood-retinal barrier. Clusterin is associated with protection from apoptotic retinal cell death. Recently, it has been demonstrated that clusterin effectively inhibited vascular endothelial growth factor-induced hyperpermeability in human retinal microvascular endothelial cells (HRMECs) and in retinal vessels from streptozotocin-induced diabetic mice. Since clusterin plays an essential role in restoring tight junctions and limiting the inflammatory response after injury (two capital features in the pathogenesis of DME), it seems reasonable to propose clusterin deficit as a contributor to DME development.
Conclusion: Proteomic analysis by DIGE was useful in identifying new potential candidates involved in the pathogenesis of DME. These results could open up new strategies in the treatment of DME.

Retinal blood flow in patients with type 1 diabetes mellitus with and without diabetic retinopathy

H.-T. Nguyen[1], E. van Duinkerken[2,3], M. Diamant[2], P.J. Ringens[1], B.C.P. Polak[1], F.D. Verbraak[4], A.C. Moll[1];
[1]Department of Ophthalmology, [2]Diabetes Centre / Department of Internal Medicine, [3]Department of Medical Psychology, [4]Department of Ophthalmology, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: Proliferative diabetic retinopathy (pDRP) is a common microvascular complication in patients with long-standing type 1 diabetes (T1DM) and is oftenly associated with poor glycemic control. However, it is currently uncertain whether T1DM, and more in particular, pDRP causes hemodynamic changes in the retina. Therefore, we measured retinal hemodynamic function in T1DM patients with and without pDRP and controls.
Materials and methods: Thirty-three T1DM patients with DRP treated with panretinal photocoagulation (pDRP), 8 T1DM patients with background retinopathy (bDRP) and 32 T1DM patients without retinopathy or other microvascular complications (nDRP) were compared to 44 controls. Retinal blood flow was measured temporal and nasal of the optic disc, using Heidelberg scanning laser doppler flowmetry. Blood flow values of the right eye were used. To control for possible effects of extreme blood glucose values, the T1DM patients had to range between 4 - 15 mmol/l. Blood was drawn to determine lipid levels and HbA1c; 24-hour urine samples were collected to determine albumine:creatinine ratio. MANCOVA corrected for age and hypertension was used to determine group differences and regression analysis for determinants of changes.
Results: Overall, the T1DM group showed increased retinal blood flow as compared to controls for both the nasal and temporal locations (both $P < 0.05$). Regression analysis showed proliferative DRP, and albumin:creatinine ratio to be positively associated with retinal flow (both $P < 0.05$). In a separate analysis, the pDRP group showed significantly higher levels of flow as compared to nDRP patients and controls. Furthermore, a linear trend for retinal blood flow across groups was found (all $P < 0.05$).
Conclusion: In T1DM as compared to controls, retinal blood flow was increased, most pronounced in patients with pDRP. The significant linear trend might be an indication of increasing retinal blood flow with increasing retinopathy severity. The increased blood flow might be a compensatory mechanism for hypoxia, caused by the closure of retinal capillaries. Interestingly, the pDRP group shows higher blood flow even though this group is treated with panretinal photocoagulation. This is most likely caused by the remaining vasculopathy and reduced number of retinal vessels after photocoagulation.

PS 117 Treatment

Positive effects of insulin in early pericyte loss

E. Berrone, E. Beltramo, S. Tarallo, M. Porta;
Internal Medicine, University of Turin, Italy.

Background and aims: Hyperglycaemia is a major risk factor for the typical alterations of diabetic retinopathy, such as loss of retinal pericytes and thickening of the basement membrane. Although many believe "pericyte drop-out" to be the result of glucose damage, the exact mechanism(s) underlining their degeneration has not been conclusively elucidated. Recently, a protective role of insulin from microvascular cell apoptosis was suggested. The objective of this study was to verify the effects of insulin on survival, intracellular glucose and expression of glucose transporters (GLUT 1, 2, 3, 4) in HRP cultured in intermittent high glucose (HGint).
Materials and methods: Pericytes were kept alternatively in high (28 mmol/l, HG) or normal (5.6 mmol/l, NG) glucose at 48h intervals for 8 days, with or without insulin (Ins) 100nM or 1μM. Control cells were cultured in stable NG or HG. GLUT transporter mRNA expression was determined by RT-PCR, intracellular glucose and apoptosis by ELISA, and cell proliferation by cell counts.
Results: HRP express GLUT 1, 3 e 4, but not GLUT2. GLUT1 expression was increased in intermittent HG (HGint) (+19.7% $p<0.05$ vs NG) but reduced when insulin was added to HGint (Ins100nM: -30.4%, Ins1μM: -31%, vs HGint). In contrast, GLUT4 was reduced in HGint (-48.7% $p<0.05$ vs NG) and increased in the presence of insulin 100nM (+34.6% $p<0.004$ vs HGint). GLUT3 mRNA was unchanged in all the above experimental conditions. In HGint, intracellular glucose levels were increased (+72.4% $p<0.05$ vs NG), and reduced by 1μM insulin (-68.3% $p<0.05$ vs HGint). Cell counts were reduced in HGint (-19,2% $p<0.05$ vs NG) and increased by insulin (Ins100nM: +49.5%, Ins1μM: +83.6%, $p<0.05$ vs HGint). Apoptosis increased with HGint ($p<0.001$ vs NG) and was completely normalized by insulin at both concentrations ($p<0.001$ vs HGint).
Conclusion: Insulin may influence the expression of glucose transporters in HRP and protect them from proliferation impairment and increased apoptosis induced by intermittent HG.

Fenofibric acid activates survival signalling and prevents activation of stress kinases in human retinal pigment epithelial cells

A.M. Valverde[1,2], S. Miranda[1,2], A. Gonzalez-Rodriguez[1,2], M. Garcia-Ramírez[3,4], C. Hernández[3,4], R. Simó[3,4];
[1]Consejo Superior Investigaciones Cientificas, Madrid, [2]CIBERDEM, Madrid, [3]Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, [4]CIBERDEM, Barcelona, Spain.

Background and aims: Diabetic retinopathy (DR) remains the leading cause of blindness among working-age individuals in developed countries. In the FIELD study on DR, fenofibrate reduced the frequency of first laser treatment for macular edema by 31% and for proliferative retinopathy by 30%. However, little is known regarding the molecular mechanisms by which fenofibrate exerts its beneficial effects. The aim of the present study was to explore for the first time the effects of fenofibric acid (the active metabolite of fenofibrate) on stress and survival signalling pathways in human retinal pigment epithelium (RPE) cell line under culture conditions mimicking the diabetic milieu.
Materials and methods: Human RPE cells (ARPE-19) were cultured in 5 mM or 25 mM glucose for 21 days. Then, some dishes were treated with fenofibric acid (100 μM) for a further 3 days. At day 3, cells were placed into the hypoxic chamber (1 % oxygen) for 6 or 24 h. As a control, some dishes were maintained under normoxic conditions. At the end of this experimental protocol, cells were harvested and collected for RNA or protein extraction. Immunoprecipitations, Western blot analysis and quantitative real-time PCR were performed.
Results: ARPE-19 cells cultured under hyperglycaemic conditions induced the expression of the hypoxia-inducible factor HIF-1α and the phosphorylation of stress-activated kinases (JNK and p38 MAPK). Under hypoxic conditions, the phosphorylation of JNK as well as its substrate c-Jun and p38 MAPK was increased in parallel with the induction of HIF-1α. This effect was increased by the combination of hyperglycaemic and hypoxic conditions. Cells pre-treated with fenofibric acid were protected against the activation of stress-inducible kinases by hyperglycaemia, hypoxia or both conditions. Moreover, fenofibric acid increased the survival signalling, measured by the expression and phosphorylation of insulin-like growth factor (IGF-I) receptor, IRS-1, IRS-2, Akt/PKB and p44/p42 MAPK, at 6 h of hypoxia plus hyperglycaemia.
Conclusion: The diabetic milieu triggers the activation of stress-inducible kinases in cultured ARPE-19 cells. Under this condition, fenofibric acid elicited a dual protective effect through the down-regulation of stress signalling and the induction of survival pathways. These mechanisms could be involved in the reported beneficial effects of fenofibrate on DR.

Fenofibrate reduces fibronectin overexpression in human retinal pigment epithelial cells cultured under conditions mimicking the diabetic milieu

S. Roy[1], K. Trudeau[1], C. Hernández[2], M. Villarroel[2], R. Simó[2], S. Roy[1];
[1]Medicine and Ophthalmology, Boston University School of Medicine, Boston, USA, [2]Diabetes and Metabolism Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron and CIBERDEM, Barcelona, Spain.

Background and aims: Diabetic retinopathy is the leading cause of blindness and vision loss in the working age population. The fenofibrate Intervention and Event Lowering in Diabetes (FIELD) study showed significant benefit of reducing the risk of microvascular complications in diabetic patients including the need for laser treatment for diabetic macular edema (DME) and proliferative diabetic retinopathy (PDR) by 30%. However, it is unclear how fenofibrate prevents the progression of DME. Having shown that inhibition of fibronectin overexpression restores blood retinal barrier in diabetes, in this study, we examined the effect of fenofibrate on fibronectin expression in a human retinal pigment epithelial (RPE) cell line under culture conditions mimicking the diabetic milieu.
Materials and methods: ARPE-19, a spontaneously immortalized human RPE cell line, was cultured for 18 days in medium supplemented with 10% fetal bovine serum in high glucose condition (25 mM D-glucose). To study the effect of fenofibrate on fibronectin expression, 100 μM fenofibric acid was added in the last 3 days of the experiment (days 19, 20, 21) to cells grown in high glucose medium or high glucose medium plus IL1β (10 ng/ml for 2 days: days 20, 21) until the end of the experiment. The combination of high glucose + IL1β was used to provoke the disruption of the monolayer, thus mimicking the effects of the diabetic milieu. The cells were subjected to serum starvation (1% FBS) during the treatments. Fibronectin expression was evaluated by real time RT-PCR and Western blot analysis. Barrier function of RPE (permeability) was assessed by measuring apical-basolateral movements of FICT-dextran (40 kDa).
Results: Compared to cells grown in normal (5.5 mM glucose) medium, cells grown in high glucose medium or in high glucose medium plus IL1b showed significant upregulation of fibronectin mRNA expression, the latter group showing a more robust (3 fold) fibronectin upregulation. Similarly, fibronectin protein expression was also upregulated in both experimental groups compared to the control. Treatment of cells with fenofibric acid significantly reduced overexpression of fibronectin both at the mRNA and protein level in cells grown in high glucose medium or cells grown in high glucose medium plus IL1β. Tubulin and beta-actin protein levels used as controls were not altered by fenofibric acid. Treatment with fenofibric acid decreased excess permeability induced by high glucose and IL1β.
Conclusion: These results indicate that downregulation of fibronectin overexpression by fenofibric acid may have a protective effect on the leakage of the outer blood-retinal barrier. This could be one of the mechanisms involved in the beneficial effects of fenofibrate against the development of excess permeability associated with diabetic retinopathy.

Puerarin inhibits advanced glycation end products-induced retinal pericyte apoptosis *in vitro* and *in vivo* by blocking Rac1-dependent signalling and the nuclear factor-kappaB pathway

J. Kim, K.M. Kim, C.-S. Kim, J.M. Kim, D.S. Jang, J.S. Kim;
Diabetic Complications Research Center, Korea Institue of Oriental Medicine, Daejeon, Republic of Korea.

Background and aims: Retinal pericyte loss is one of the histopathological hallmarks of early diabetic retinopathy. Puerarin (4'-7-dihydroxy-8-beta-d-glucosylisoflavone), an isoflavone-C-glucoside isolated from *Puerarin lobata*, has various pharmacological effects, including anti-hyperglycemic and anti-inflammatory activities.
Materials and methods: In the present study, we determined the efficacy and the possible mechanism of puerarin on advanced glycation end products (AGEs)-induced apoptosis of cultured bovine retinal pericytes and retinal microvascular cells in intravitreally AGEs-modifed rat serum albumin-injected eyes of rats. We also examined the potential preventive effect of puerarin on diabetic retinopathy in streptozotocin (STZ)-induced diabetic rat. Puerarin (10 and 50 mg/kg body weight) was treated once a day orally for 16 weeks.
Results: Puerarin significantly inhibited pericyte apoptosis as well as reactive oxygen species (ROS) generation, NADPH oxidase activity and phosphorylation of Rac1 and p47phox induced by AGEs treatment. Further studies revealed that puerarin treatment remarkably suppressed the activation of nuclear factor-kappaB (NF-κB). In vivo retinal pericyte apoptosis of rats evoked by intravitreally injection of AGEs was evidently attenuated by the treatment of puerarin. In addition, the long-term administration of puerarin also prevented several histological changes, such as pericyte ghost and acellular formation of capillaries in STZ-induced diabetic rats. In fluorescein angiography, the changes of retinal vasculature (non-perfusion of fluorescein, fluorescein leakage and vessel narrowing) were significantly reduced in STZ-induced diabetic rats treated with puerarin.
Conclusion: These results demonstrate that puerarin may exert inhibitory effects on AGEs-induced pericyte apoptosis via interfering with Rac1-dependent ROS pathways and blocking NF-κB activation, thus resulting in the amelioration of diabetic retinopathy in STZ-induced diabetic rats.

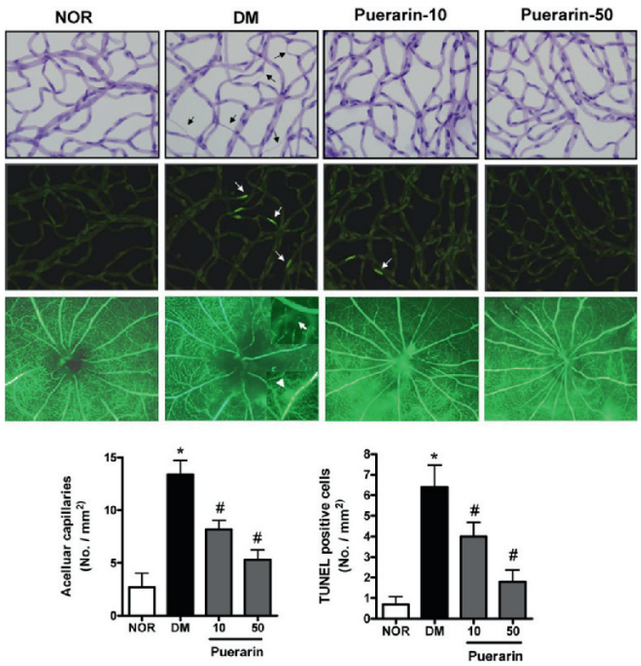

Figure 1. Effects of puerarin on diabetic retinopathy. The trypsin-digested retinal vessels from a normal rat (NOR), STZ-induced diabetic rat (DM) and diabetic rat treated with peurarin (10 and 50mg/kg, Puerarin-10 and -50) were stained with Periodic acid-Schiff and TUNEL. Acelluar capillary (black arrow) and TUNEL-positive retinal pericytes (white arrow) were observed in STZ-induced diabetic rats. In fluorescein angiography, white thick arrow and white arrowhead indicate the vessel narrowing and fluorescein leakage, respectively. All data were expressed as mean±SE. *p<0.01 vs. normal rat, #p<0.01 vs. diabetic rat.

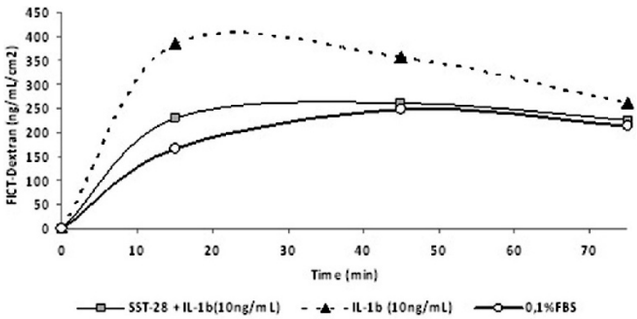
Somatostatin 28 (SST-28) prevents the breakdown of human retinal pigment epithelial cells induced by the diabetic milieu

L. Corraliza, M. Garcia-Ramírez, M. Villarroel, A. Ciudin, C. Hernández, R. Simó;
CIBERDEM (Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas) (Instituto de Salud Carlos III) and Diabetes Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Spain.

Background and aims: Diabetic macular edema (DME) results from fluid accumulation due to the breakdown of the inner and outer blood retinal barriers (BRBs). The outer BRB is formed by the tight junctions (TJs) between retinal pigment epithelial (RPE). Somatostatin (SST) has been involved in the transport of water and ions in several tissues. Various ion/water transport systems are located on the apical side of the RPE, adjacent to the subretinal space, and, indeed, a high expression of SSTR2 has been shown in this apical membrane of the RPE. In addition, we have previously demonstrated a significantly lower intravitreous concentration of SST in patients with DME in comparison with non-diabetic control subjects, being SST-28 the main molecular variant accounting for this deficit. These findings suggest that SST could have a relevant physiological role in preventing fluid accumulation within the retina, and the deficit of retinal SST observed in diabetic patients could favour the development of DME. On this basis, the aim of the study was to explore the SST effects on the outer BRB permeability in a human retinal pigment epithelial (RPE) cell line under culture conditions mimicking the diabetic milieu.
Material and methods: ARPE-19 cells (an spontaneous immortalized RPE cell line) were cultured in hyperglycemic conditions (25 mM D-glucose) for 18 days at 37ºC under 5% CO_2 in medium (DMEM/F12) supplemented with 10% fetal bovine serum. SST-14 and SST-28 ($1x10^{-7}$ M) were added to the apical side of the monolayer the last 4 days of the experiment (days 14, 15, 16 and 17) (1 application/day). Cells were also treated with IL1β (10 ng/ml) for 48 hours until the end of the experiment in order to mimic the diabetic milieu (days 16, 17). The permeability of RPE cells was determined at 18 days by measuring the apical-to-basolateral movements of fluorescein isothiocyanate (FICT) dextran (70 kDa). Lactate dehydrogenase production and cell count was used to determine putative changes in the citotoxicity or proliferation related to the different treatments.
Results: Treatment of ARPE-19 cells with SST-28 ($1X10^{-7}$) was able to prevent the increase of permeability induced by IL-1β. By contrast, treatment with SST-14 did not produce significant changes on monolayer permeability. No differences in cell number or citotoxicity were observed among the different treatments.
Conclusion: SST-28 but not SST14 has a significant protective effect on RPE disruption caused by conditions mimicking the diabetic milieu. Further investigation addressed to determining the mechanisms by which SST-28 exerts its effects in reducing permeability and their potential efficacy in DME treatment are needed.



Results of 70 kDa FICT-Dextran Permeability

Efficacy and safety of ranibizumab monotherapy or adjunctive with laser versus laser therapy in patients with diabetic macular oedema: 12-month results of the RESTORE study

P. Massin, on behalf of the RESTORE study group;
Ophthalmology, Hôpital Lariboisière, Paris, France.

Background and aims: Diabetic macular edema (DME) is the leading cause of blindness in diabetic patients (pts). The pathogenesis of DME is characterized by elevated levels of vascular endothelial growth factor (VEGF) in the vitreous of patients. The RESTORE study was designed to demonstrate superiority of ranibizumab 0.5mg monotherapy or as adjunctive therapy to laser photocoagulation compared to laser alone, based on mean best-corrected visual acuity (BCVA) change from baseline over 12 months in patients with DME. We present the 12-month efficacy and safety results of the RESTORE study.
Materials and methods: Randomized, double-masked, multicenter, laser controlled Phase III study of 12 months duration with ranibizumab 0.5mg in DME pts. A total of 345 pts were randomized in a 1:1:1 ratio to one of the three treatment arms: intravitreal ranibizumab 0.5mg and sham laser (ranibizumab) or ranibizumab adjunctive to laser (ranibizumab + laser) or sham injections plus laser (laser) for 12 months. The primary endpoint was the mean change of BCVA from baseline (bsl) to the average BCVA from Month 1 to 12. Treatment arm difference relative to laser were analyzed as least square means [dLSM]) using a two-sided stratified Cochran-Mantel-Haenszel test. Key secondary endpoints were mean BCVA change, safety assessed by 12-month incidence of adverse events (AEs).
Results: A total of 88% pts completed the study. The superiority of ranibizumab compared to laser was demonstrated when administered both as monotherapy and as an adjunct therapy to laser treatment with mean average BCVA changes (SD) of 6.1 (6.43), 5.9 (7.92), 0.8 (8.56), respectively (dLSM: 5.4 [ranibizumab] and 4.9 [ranibizumab + laser], both [p<0.0001]). The incidence of ocular serious AEs was low (2 pts in each of the ranibizumab + laser and laser arms). Non-ocular serious AEs were reported in 19.8% (ranibizumab), 14.4% (ranibizumab + laser) and 13.5% (laser) pts. Two deaths were reported in each treatment arm, none of which were suspected to be related to study drug or injection procedure. Ocular AEs were reported in 42.2% (ranibizumab), 43.2% (ranibizumab + laser), 38.7% (laser); eye pain being the most frequently reported ocular AE (9-10%). Non-ocular AEs were reported in 57.8% (ranibizumab), 46.6% (ranibizumab + laser) and 61.3% (laser) pts; nasopharyngitis being the most frequently reported non-ocular AE (10-14%).
Conclusion: Ranibizumab monotherapy or as adjunctive therapy with laser photocoagulation provided significantly superior benefits in BCVA as compared to laser therapy. No new safety findings were identified for ranibizumab in either arm within this study.

Green tea (Camellia sinensis) ameliorates the oxidative stress and nitric oxide synthase isoforms in the retina of diabetic hypertensive rats

K.C. Silva, M.A.B. Rosales, J.B. Lopes de Faria, J.M. Lopes de Faria;
Faculty of Medical Sciences, State University of Campinas, Brazil.

Background and aims: Green tea (GT, *Camellia sinensis*), a popular beverage consumed in some parts of the world, is a rich source of polyphenols and acts as an antioxidant, antiproliferative, antitumor, and anti-angiogenic, so also may be useful to prevent diabetes in humans. A polyphenolic constituent, (-)-epigallocatechin-3-gallate (EGCG), is the major and most effective chemopreventive agent in GT. Because several lines of evidence suggest that oxidative stress and nitric oxide (NO) system contributes to the pathogenesis of diabetic retinopathy (DR), we tested the hypothesis that GT prevents retinal oxidative/nitrosative stress and thus ameliorating the early markers of DR.
Materials and methods: Diabetes was induced in spontaneously hypertensive rats (SHR) with 12 week-old. Control rats received only vehicle (citrate buffer). The diabetic SHR (DM-SHR) groups were assigned to receive or not receive, daily freshly prepared GT (13.3 g/L). After 12 weeks, the animals were euthanized and the retinas collected. The results were compared by Analysis of Variance (ANOVA) followed by Fisher's protected least significant difference test.
Results: As expected, body weight was lower and glycaemia was greater in diabetic SHR's than in non-diabetic rats ($p < 0.0001$); the systolic blood pressures were equal in all studied groups. The early molecular markers of DR were evaluated through glial reaction by expression of glial fibrillary acidic protein (GFAP) and blood retinal barrier breakdown by the estimation of the tight junction protein expression occludin. It was observed that there was a significant increase in GFAP expression (p=0.0003) and a decrease in occludin levels in retina (p=0.01) of non-treated DM-SHR group compared with control rats. Retinal oxidative damage evaluated by immunohistochemistry for 8-hydroxy-2'-deoxyguanosine (8-OHdG) and nitrotyrosine (NT) levels, were greater in diabetic than in nondiabetic rats (p<0.0001 for 8-OHdG and p=0.04 for NT). Similarly, the retinal inflammation estimated by immunolocalization of ED1/microglial positive cells was significantly higher in diabetic than in control SHR's (p=0.003). The phospho-serine isoforms of neuronal (Ser 847-nNOS) and endothelial nitric oxide synthases (NOS) (Ser 113-eNOS) were also increased in retina of diabetic SHR rats compared with control (p=0.0002 for Ser 847-nNOS and p=0.02 for Ser 113-eNOS). The Cu/Zn superoxide dismutase enzyme (Cu/Zn-SOD), an important antioxidant defense, was marked elevated only in animals which received oral treatment with GT compared with no treated groups (p=0.0006). The treatment with GT reestablished all of the above-mentioned parameters.
Conclusion: GT prevented the oxidative damage and reduced the activation of the constitutive NOS isoforms in retina from diabetic hypertensive rats. As a consequence, it was observed an ameliorating in DR indicators. These findings suggest that GT displays protective effects against retinal diabetic disease.

Diabetic retinopathy before and after cataract surgery

S. Khutsurauli[1], A. Memarne[2], R. Kurashvili[3], L. Tsutskiridze[3];
[1]High Medical School "Aieti", [2]High Medical School, [3]Georgian Diabetes Center, Tbilisi, Georgia.

Background and aims: Increased retinopathy progression has been reported after cataract surgery in patients with diabetes mellitus. To assess the influence of cataract surgery on visual acuity and retinopathy progression, all diabetic patients who were subjected to cataract surgery during 2007-2009 have been followed up at the Ophthalmology Clinic.
Materials and methods: One eye of each of 70 patients was included in the study, 35 monocularly and 35 binocularly operated on. Sixteen of the 70 patients had proliferative diabetic retinopathy (PDR) at baseline. The degree of glycaemic control was assessed by measurements of HbA1c.
Results: Most patients obtained improved visual acuity; a postoperative visual acuity of 0.5 or better was achieved in 89% of diabetic surgical eyes. Progression of the retinopathy occurred in 30 out of the 70 eyes, and was associated with mean level of HbA1c (p=0.04), duration of diabetes (p=0.02), insulin treatment (p=0.001), and presence of retinopathy at baseline (p=0.01). Patients who progressed had a significantly higher incidence of macular oedema (p=0.006) than those who did not progress. No significant differences were found when operated and non-operated eyes were compared in the 35 patients with monocular surgery. Two patients in this group, however, ended up with macular oedema and worse vision in the operated eye than in the eye which was not operated on. Both patients had background retinopathy before surgery.
Conclusion: Patients in this study, also those with PDR, obtained good visual acuity, better than in most previous studies. Poor glycaemic control was a factor of importance for the progression of diabetic retinopathy after cataract surgery.

PS 118 Diabetic nephropathy: clinical observations

Prescription of medications: Cumulative costs in outpatients with type 1 diabetes (The FinnDiane Study)

R.H. Lithovius[1,2], V. Harjutsalo[1,2], P.-H. Groop[1,2], C. Forsblom[1,2], FinnDiane Study Group;
[1]Institute of genetics, Folkhälsan Research Center, [2]Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

Background and aims: Diabetes' high prevalence, chronic nature, and its association with complications increase the use and the costs of medications. The identification of subgroups of patients may give a more precise view of the real costs. The aim of this study was to estimate the cumulative costs of medications according to the complication status and duration of diabetes.
Materials and methods: The Finnish Diabetic Nephropathy Study (FinnDiane) data (N=3 721) were linked to the Drug Prescription Register (mean age 39.1±11.8 yrs, 51% men, mean duration of diabetes 30.9±11.4 yrs). 11-year cumulative costs of medication for each patient were calculated between 1998 and 2008. Costs were inflated to year 2008 Euros using the Consumer Price Index. Patients were divided in 10-year groups according to the duration of diabetes in 1998. Data on macrovascular diseases (MVD) and progression to end stage renal disease (ESRD) were retrieved from follow-up visits, medical files, or death certificates for all patients until 2008. One quarter of patients (n=883) had MVD (stroke, AMI, CHD, coronary revascularization, amputation) and/or ESRD (dialysis, kidney transplantation). Based on the complication status the patients were divided into 4 groups: no MVD or ESRD, MVD only, ESRD only, and both MVD and ESRD. Generalized linear mixed models were used to evaluate the 11-year cumulative costs. Costs were adjusted for age, sex, duration of diabetes, total insulin dose/day and body mass index, complication status and contributing years.
Results: The observed cumulative medication costs were 11 000 (no MVD or ESRD), 15 200 (MVD only), 80 900 (ESRD only), and 67 200 € (both MVD and ESRD) in the respective complication status groups. The average costs per year were 1 000, 1 600, 8 000, and 7 500 €, respectively. On average men's costs were 16% higher than women's. After adjustment, the cumulative costs of medications were 65% higher when MVD was present (increased from 11 600 to 19 000 € per patient). Notably, costs increased substantially when ESRD was present, being 7.5 times higher and, when antidiabetic medications (ATC A10) were excluded, even 22 times higher. The costs were approximately 10% lower when both MVD and ESRD were present probably due to the high mortality rate in this group (54% of the patient died during 1998 - 2008) and hospitalisation (inpatient medications costs were not included). The costs of antidiabetic medication remained rather stable, irrespective of complication status or duration of diabetes. However, when complications were present these costs were markedly lower in all 10-year duration groups. Without complications the costs of medications related to comorbidity (other than ATC A10) were rather low in all duration groups (3 000 - 5 700 €). In contrast, with complications these costs increased remarkably.
Conclusion: The cumulative costs of medications increased substantially when ESRD was present. Since no considerable differences were observed in the costs of antidiabetic medications, the observed increase was entirely due to the increase in the costs of medications related to comorbidity.

1196

Cardiovascular risk factors differ between type 2 diabetic patients with and without renal impairment

M.K. Svensson[1], J. Cederholm[2], B. Eliasson[1], B. Zethelius[3], H. Afghahi[4], H. Hadimeri[4], S. Gudbjörnsdottir[1];
[1]Department of Medicine, Sahlgrenska Academy at the University of Gothenburg, [2]Department of Public Health and Caring Sciences, Family Medicine and Clinical Epidemiology, Uppsala University, [3]Department of Public Health and Caring Sciences/Geriatrics, University of Uppsala, [4]Department of Nephrology, Kärnsjukhuset, Skövde, Sweden.

Background and aims: Diabetes, albuminuria and renal impairment are all major determinants of cardiovascular disease. The aim of this cross-sectional study was to assess potential differences in cardiovascular risk factors in type 2 diabetic patients with and without renal impairment. This was done in National Diabetes Register (NDR), a large nation-wide population-based diabetes register.
Materials and methods: 62 661 patients with T2D aged 18-80 years with complete datasets on albumin excretion, renal function (serum creatinine) and clinical characteristics reported to the Swedish National Diabetes Register in 2008 were included. Albuminuria was defined as urinary albumin excretion rate > 20 μg/min and renal impairment as estimated glomerular filtration rate; eGFR< 60 ml/min/1.73 m2 according to MDRD. Values are given as crude means and standard deviations (SDs). In addition, data was analysed with least square (LS) means and frequencies, standard errors (SE) for clinical characteristics, comparing patients with renal impairment and those with no renal impairment at GLM regression adjusting for all other variables. P-values for each variable are given after these adjustments.
Results: 15% of all patients had renal impairment (n=9 308) and 58% of these patients were non-albuminuric. Several differences in cardiovascular risk factors were found between patients with and without renal impairment. Patients with renal impairment were older (71.2±6.7 vs. 64.0 ±9.3), had a longer diabetes duration (11.1±7.7 vs. 7.8±6.4 years), were more often women (50 vs. 40%), had significantly lower total- and HDL-cholesterol (4.6±1.0 vs. 4.7±1.0 and 1.23±0.4 vs. 1.28±0.4 mmol/L, respectively), higher triglycerides (2.0±1.2 vs. 1.8±1.1 mmol/L), higher HbA1c (7.1±1.1 vs. 7.0± 1.1 % (DCCT)), higher BMI (30.2±5.3 vs. 29.7±5.2 kg/m^2) and higher systolic blood pressure (138±18 vs. 137±16 mmHg). In addition, fewer patients with renal impairment performed physical activity >3 times a week (44 vs. 52%) and a smaller proportion were smoking (10 vs. 15%) (All p-values <0.001) compared to patients without renal impairment. When patients with renal impairment were compared with those without renal impairment at GLM regression adjusting for all other variables similar relationships were found for all variables except for HbA1c and systolic blood pressure where adjusted values were lower in patients with renal impairment (7.0±0.01 vs. 7.1± 0.01 % (DCCT) and 135±0.2 vs. 137±0.1 mmHg) (adjusted LS means±SE).
Conclusion: The majority of patients with type 2 diabetes and renal impairment were non-albuminuric. Several differences in cardiovascular risk factor pattern were found between type 2 diabetic patients with and without renal impairment. Interestingly, patients with renal impairment had better glycemic control and blood pressure when adjusting for all other variables. This finding should be further investigated. The cause-effect relationship and potential treatment effects could not be assessed in this cross-sectional study and thus prospective studies are warranted.

1197

Relation between echocardiography and coronary artery disease in asymptomatic type 2 diabetic patients with elevated urinary albumin excretion rate

H. Reinhard[1], P.R. Hansen[2], N. Wiinberg[3], C.L. Petersen[3], H.-H. Parving[4,5], P. Rossing[1], P.K. Jacobsen[1,6];
[1]Steno Diabetes Center, Gentofte, [2]Department of Cardiology, Gentofte University Hospital, [3]Department of Clinical Physiology and Nuclear Medicine, Frederiksberg University Hospital, [4]Department of Medical Endocrinology, University Hospital of Copenhagen, [5]Faculty of Health Science, Aarhus University, [6]The Heart Centre, University Hospital Rigshospitalet, Copenhagen, Denmark.

Background and aims: Coronary artery disease (CAD) is the major cause of morbidity and mortality in type 2 diabetic patients, especially in patients with elevated urinary albumin excretion rate. Left ventricular (LV) hypertrophy and systolic/diastolic abnormalities has been suggested as part of the diabetic cardiomyopathy, but relation to CAD is unclear. This study examined echocardiographic parameters, including LV mass index, LV systolic and diastolic function, and their relation to screen detected previously undiagnosed CAD in type 2 diabetic with urinary albumin excretion rate (UAER) >30mg/24h.
Materials and methods: The study included 200 type 2 diabetic patients without prior clinical CAD. Patients with plasma NT-proBNP >45.2 ng/L and/or coronary calcium score >400 were arbitrarily stratified as high risk patients for CAD (n=133), and all other patients as low risk patients (n=67). High risk patients were examined by myocardial perfusion imaging (MPI; n=109), and/or CT-angiography (CTA; n=20), and/or coronary angiography (CAG; n=86). LV systolic and/or diastolic dysfunctions were evaluated in all patients by conventional echocardiography and tissue Doppler imaging. Moderate-severe LV hypertrophy was defined by LV mass index >131 g/m^2 in men and >108 g/m^2 in women.
Results: Patients received multifactorial treatment, yielding mean (SD) HbA_{1c} 7.9 (1.3)%, plasma total cholesterol 3.9 (0.9) mmol/L and arterial blood pressure 130 (17)/75 (11) mmHg. The LV mass index was 87 (21) g/m^2 and 8 (4%) patients had moderate-severe LV hypertrophy. LV systolic function was well preserved (LV ejection fraction 59 (5)%) and impaired (<50%) in only 5% of patients. LV diastolic dysfunction (LVDD) was found in 109 patients (54.5%),

of whom 7 (3.5%) had impaired relaxation and 102 (51%) had a pseudonormal pattern of LV filling. In 70 high risk patients, significant CAD was demonstrated by MPI, and/or CAG. In a multiple regression model, the adjusted odd ratio (OR, 95% CI) for having significant CAD was 2.91 (1.41-6.00) in patients with LV mass index above the median. Patients with right atrial volume above the median (>49.1 ml) had higher risk of CAD (unadjusted OR 2.20 (1.06-4.56) than other patients. LVDD was not associated with LV mass index or significant CAD but was associated with poor metabolic control (adjusted OR 1.46 (1.14-1.87) per 1% increase of HbA_{1c} (p=0.003)).
Conclusion: In our study of asymptomatic type 2 diabetic patients with elevated UAER but receiving multifactorial treatment, the prevalence of abnormal LV mass and function was low. However, even within normal range LV mass index was an independent predictor of significant CAD. LVDD was common but not associated with CAD.

Changes in skin microcirculation and large arterial vessels in patients with diabetic nephropathy
M. Walus-Miarka[1], P. Miarka[2], M. Dubiel[3], M. Stompór[3], E. Chowaniec[2], M. Krzanowski[2], T. Grodzicki[3], B. Idzior-Walus[1], W. Sulowicz[2];
[1]Department of Metabolic Diseases, [2]Department of Nephrology, [3]Department of Internal Medicine, Medical College, Jagiellonian University, Krakow, Poland.

Introduction: Diabetic vascular complications are divided into microangiopathies (pertaining to microvasculature) and macroangiopathies (pertaining to large vessels) that lead to the development of atherosclerosis that clinically manifests as ischemic heart disease or cerebral stroke. Increasing vessels stiffness and intima-media thickness (IMT) are indicators of macroangiopathy progression. Abnormalities of microcirculation are the basis of microvascular complications in diabetes and present in many organs. The doppler laser method allows for direct evaluation of skin microcirculation.
Aim: Study aim was to assess changes in the macro - and microcirculation in patients with diabetic nephropathy, as well as the influence of nephroprotective therapy on the evaluated parameters.
Materials and methods: 70 patients diagnosed with diabetes mellitus type II were studied: group 1- 48 patients with nephropathy, group 2 - 22 patients with diabetes mellitus without vascular complications (comprising the control group), and group 3- 25 patients with nephropathy, examined 36 months post intensive nephroprotective therapy. Visual diagnostic procedures evaluating macro- and microvessels were performed in all patient groups using usg (IMT) and laser doppler [skin mean basal flow (MFb), post occlusion flow (PF)].
Results: In the group with diabetic nephropathy, significantly higher values of PWV, as well as IMT were noted in cervical arteries when compared to the control group (p<0.01). In this group, significantly slower flow in microcirculation (MFb) at rest was noted (p< 0.01); as well as post occlusion (PF) (p=0.05) when compared to the group without complications. After 36 months of nephroprotective therapy in the studied group - stabilization of renal function was found and no substantial differences were noted in aortic pulse wave velocity (AoPWV) and also in IMT when compared to initial values at the beginning of the study. However, improvement was noted in skin microcirculation parameters when compared to initial values (p= 0.05); as well as a trend for improvement of maximal flow post occlusion (p= 0.09) and at the temperature of 44°c (MF44) (p= 0.05). Results are presented in the table.
Conclusion: Study results point to an existence of advanced atherosclerotic changes and decreased microcirculation skin flow in the group of patients with nephropathy than in the patient group without diagnosed nephropathy. After 36 months of observation and intensive nephroprotective therapy - stabilization of macrocirculation changes and regression of skin microcirculatory abnormalities were observed.

Serum uric acid is related to cardiovascular events and correlates to NT-proBNP and albuminuria in patients with diabetes mellitus
M. Clodi[1], M. Resl[1], H. Kormoser[1], S. Neuhold[2], M. Hülsmann[2], A. Luger[1], R. Pacher[2];
[1]Department of Endocrinology and Metabolism, [2]Department of Cardiology, Medical University of Vienna, Austria.

Background and aims: Hyperuricemia is a risk factor for cardiovascular events and renal insufficiency. It correlates to intima media thickness and microalbuminuria. The aim of this study was to evaluate the relationship between NT-proBNP as an established marker for subclinical cardiovascular disease and uric acid in patients with diabetes mellitus.
Materials and methods: In a prospective observational study we recruited 494 patients with diabetes mellitus. Serum uric acid, NT-proBNP, urinary albumin to creatinine ratio and HbA1c as well as other cardiovascular risk factors were evaluated at baseline. Patients were then followed for 12 months and hospitalisations due to cardiac events (ischemic heart disease, rhythm disturbances, heart failure) were recorded.
Results: The mean duration of diabetes was 13 ± 11 years. Patients were 60 ± 13 years old and mean HbA1c was 7.7 ± 3.2%. At baseline mean uric acid was 5.3 ± 1.6 mg/dl, NT-proBNP was 248 ± 412 pg/ml and mean urinary albumine to creatinine ratio was 96 ± 361 mg/g; Uric acid significantly correlated to NT-proBNP (r= 0.258 p < 0.001) and urinary albumin to creatinine ratio (r = 0.198 p< 0.001). In a logistic regression model including the variables uric acid, NT-proBNP, systolic blood pressure and urinary albumin to creatinine ratio, NT-proBNP was the best predictor of cardiac events (Hazard Ratio 1.002, Wald 37.2 p < 0.001). In a second step uric acid provided additional prognostic information (Hazard Ratio 1.353 Wald 7.0 p < 0.05).
Conclusion: Serum uric acid is a predictor of cardiac events and correlates to NT-proBNP underscoring the importance of uric acid as a cardiovascular risk marker in patients with diabetes mellitus.

Serum osteoprotegerin is related coronary artery calcification, urinary albumin excretion, and diabetic retinopathy in Japanese patients with type 2 diabetes
N. Takebe, M. Masaya, K. Nagasawa, T. Takahashi, H. Honma, M. Yamashina, M. Ishii, F. Fujiwara, T. Kajiwara, H. Taneichi, K. Takahashi, J. Satoh;
Division of Diabetes and Metabolism, Department of Internal Medicine, Iwate Medical University, Morioka, Japan.

Background and aims: Osteoprotegerin (OPG), a secreted glycoprotein identified as an inhibitor of bone resorption, has recently been indicated to act as an important regulatory molecule in the vasculature. Recent studies also suggest that serum OPG levels are associated with endothelial dysfunction, coronary artery calcification (CAC), and micro- and macroangiopathy in Type 2 diabetes, and, in addition, diabetic microangiopathy is correlated with macroangiopathy. However, a mechanism(s) underlining a relationship between diabetic macro- and microangiopathy is unclear. Therefore, we have measured serum OPG levels and cross-sectionally investigated relationships among OPG levels, macroangiopathy, and diabetic microangiopathy (retinopathy and nephropathy) in 82 Japanese patients with type 2 diabetes mellitus.
Materials and methods: Blood samples were obtained in fasting state. Variables analyzed were age, sex, blood pressure, BMI, waist/hip ratio, daily blood glucose profile, M value and MAGE as markers of blood glucose fluctuation, HbA1c, glycated albumin (GA), serum levels of OPG, IRI, TC, TG, HDL-C, LDL-C, Lp(a), uric acid (UA), homocysteine, adiponectin, leptin, and PAI-1, and urine C-peptide (CPR), surrogate markers of macroangiopathy [carotid IMT and plaque, pulse wave velocity (PWV), ankle-brachial index (ABI), and CAC score (CACS)], and presence of microangiopathy [DR > simple retinopathy, and urine albumin excretion (UAE) as a marker of nephropathy].
Results: Serum OPG levels were positively correlated with age, DM duration, systolic BP, PWV, log(CACS+1), BUN, logUAE, and presence of DR, whereas inversely with U-CPR, and postprandial glucose excursion. Multiple regression analysis showed that significantly independent predictors for the OPG levels were systolic BP and DR. Log(CACS+1) tended to be significant. On the next step, we analyzed focusing on an association of macroangiopathy [log(CACS+1)], and micropangiopathy (DR and logUAE) with the serum levels of OPG. Log(CACS+1) was positively correlated with OPG levels, age,

waist, systolic BP, PWV, IMT, BUN, UA, postprandial glucose excursion, and MAGE, whereas inversely with ABI. Multiple regression analysis showed that independent predictors for log(CACS+1) were OPG, DR, age, and waist. In comparison with patients without DR, those with DR had significantly higher levels of serum OPG, DM duration, PWV, UA, and log(CACS+1), whereas significantly lower levels of HDL, U-CPR, and diastolic BP. Logistic analysis revealed that independent predictors for DR were OPG levels, diastolic BP, GA, and log(CACS+1). Finally, logUAE was positively correlated with OPG, SBP, PWV, UA, LDH, and postprandial glucose excursion. Multiple regression analysis showed that independent predictors for logUAE were OPG, ABI, PWV, and MAGE.
Conclusion: Thus, these results indicate serum OPG level was an independent predictor for CAC, DR, and UAE, and vice versa in Japanese patients with type 2 diabetes. The results imply that there may be a bilateral interaction between coronary artery atherosclerosis, diabetic retinopathy and nephropathy in Type 2 diabetic patients.

Chronic cigarette smoking could contribute to diabetic nodular glomerulosclerosis
R. Halmai, I.A. Szijártó, P. Degrell, Á. Mérei, P. Brasnyó, I. Wittmann;
2nd Department of Internal Medicine, University of Pécs, Medical Faculty, Hungary.

Background and aims: Nodular glomeruloclerosis, glomerulomegaly, thickening of glomerular basement membrane and arteriolar hyalinosis are present both in diabetic nephropathy with nodular glomerulosclerosis and in idiopathic nodular glomerulosclerosis, which suggests a common mechanism. Chronic smoking is known as a risk factor in the former and a potential causative factor in the latter disease. We hypothesized that there are more smokers among patients with diabetic nephropathy with glomerulosclerosis (DNP + NGS), than among patients with diabetic nephropathy without nodular glomerulosclerosis (DNP without NGS).
Materials and methods: A retrospective analysis of all native renal biopsy specimens (n=890) available in the Renal Pathology Laboratory at our clinic from 2002 to 2009 was performed. The characteristics of patients were collected from medical documents and the smoking habits were confirmed by a questionnaire.
Results: The data revealed significantly more smokers (10 out of 11) among patients with diabetic nephropathy and nodular glomerulosclerosis compared to the random selected patients (4 out of 10) with diabetic nephropathy without histological signs of nodular glomerulosclerosis (p=0.024). Between the two group of patients (DNP + NGS and DNP without NGS) no significant difference was found in the age (56±14.7 vs. 53.7±7.7years, p=0.875), body mass index (30.5±5.6 vs. 31.9±4.1 kg/m2, p=0.578), duration of diabetes mellitus (12.11±5.67 vs. 8.89±6.51 years, p=0.279), prevalence (89% both) and duration (10.43±8.92 vs. 12.25±13.55 years, p= 0.573) of hypertension, serum total cholesterol (7.5±5.3 vs. 6.9±2.2mmol/l, p=0.781), serum triglyceride (4.5±4.4 vs. 2.8±1 mmol/l, p=0.344), serum creatinine (225.6±136.2 vs. 180.6±88.1, p=0.479), estimated (MDRD) renal function (39.51±24.58 vs. 45.24±26.92ml/min, p= 0.685) and the renin-angiotensin system blocker treatment (100% vs. 75%, p=0.155) at the time of the kidney biopsy.
Conclusion: Our results show, that chronic cigarette smoking could be a potential cause of nodular glomerulosclerosis seen in diabetic nephropathy patients.

1202

Erythropoetin therapy affects HbA_{1c} levels in patients with diabetes mellitus and chronic kidney disease not on haemodialysis
J.M. Ng[1], M. Cooke[2], S. Bhandari[2], S.L. Atkin[1], E.S. Kilpatrick[2];
[1]Hull York Medical School, [2]Hull Royal Infirmary, United Kingdom.

Background and aims: Glycated haemoglobin (HbA1c) is the most widely accepted and used method of assessing chronic glycaemia in patients with diabetes mellitus (DM). Treatment of anaemia in patients with chronic kidney disease (CKD) using erythropoietin stimulating agents (ESAs) has resulted in significant improvements to quality of life and levels of anaemia without the need for blood transfusions . Although some studave shown a fall in HbA1c in patients treated with ESA therapy it is not known whether there is a change in mean blood glucose. This study has therefore sought to establish the effect of ESA therapy on both HbA1c and mean blood glucose amongst a group of patients with diabetes and known CKD.
Materials and methods: This was a prospective study of patients with DM and CKD stage III or IV selected for treatment with erythropoietin stimulating agents (ESA) from Jan 2009 to December 2009 inclusive. All patients were requested to perform 7 point glucose monitoring (7PGM) 3 times weekly for a month before commencement of ESA until the end of the study. Continuous glucose monitoring (CGMS) was performed measurements of interstitial glucose levels were made. Mean blood glucose (MBG) of each patient was calculated by averaging daily capillary glucose readings on days where patients had more than 3 readings a day or more and discerning the results of the CGMS.
Results: There were 15 patients (11M 4F, median age 70 (IQR 62,75)) with Type 2 DM. The mean follow up time of was (mean±SD) 17.3±3.3 weeks. There was a statistically significant rise in haemoglobin and haemotocrit levels following ESA therapy and no significant change in the eGFR. The HbA1c levels fell without discernible alteration in glycaemic control. The mean HbA1c fell from 7.3 to 6.6% (p=0.001, paired t test). This change occurred in the presence of a MBG which remained unchanged (8.7 mmol/L vs 8.7 mmol/L, p= 0.89).
Conclusion: Anaemia is a common phenomenon in patients with CKD. This study confirms the fall in HbA1c as a result of ESA treatment and proves that this is independent of a change in glycaemia. In these patients, therefore, alternative markers of glycaemia are needed to accurately assess their glucose control.

Patients on ESA therapy

	Before ESA mean (95% CI)	After ESA mean (95% CI)	p (paired t test)
HbA1c(%)	7.31 (6.42,8.54)	6.63 (6.03,7.36)	0.01
Hb (g/dl)	9.52 (9.18,9.86)	11.51 (11.15,11.85)	<0.01
Haematocrit	0.324 (0.296,0.350)	0.378 (0.341,0.398)	<0.01
Mean blood glucose (mmol/L)	8.72 (7.31,10.12)	8.78 (7.47,9.99)	0.89

1203

Irbesartan treatment does not influence plasma levels of the advanced glycation end products CML and CEL in patients with type 2 diabetes and microalbuminuria. An IRMA2 substudy
L. Engelen[1,2], F. Persson[3], I. Ferreira[1,4], P. Rossing[3], P. Hovind[3,5], T. Teerlink[6], C.D.A. Stehouwer[1,2], H.-H. Parving[7,8], C.G. Schalkwijk[1,2];
[1]Internal Medicine, Maastricht University Medical Centre, Netherlands, [2]Cardiovascular Research Institute Maastricht (CARIM), Netherlands, [3]Steno Diabetes Center, Gentofte, Denmark, [4]Clinical Epidemiology and Medical Technology Assessment (KEMTA), Maastricht University Medical Centre, Netherlands, [5]Clinical Physiology and Nuclear Medicine, Glostrup Hospital, Denmark, [6]Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands, [7]Medical Endocrinology, University Hospital of Copenhagen, Denmark, [8]Faculty of Health Science, University of Aarhus, Denmark.

Background and aims: Guidelines state that patients with type 2 diabetes who develop microalbuminuria should be treated with angiotensin receptor blockers (ARBs). In vitro studies and animal experiments have shown inhibiting effects of ARBs on advanced glycation end products (AGEs), which are known to be involved in the development of cardiovascular complications in diabetes. However, human data to confirm such beneficial effects of ARBs are lacking.
Materials and methods: We analysed data from a multicentre, double-blind, randomised controlled trial in patients with type 2 diabetes and microalbuminuria, the primary goal of which was to examine the renoprotective effects of irbesartan (150 or 300 mg once daily). Secondary endpoints included, among others, measures of the plasma levels of the AGEs N^{ε}(carboxymethyl)lysine (CML) and N^{ε}(carboxyethyl)lysine (CEL) in the treatment arm receiving 300 mg irbesartan (n =139) and in the placebo group (n =125). Effects of treatment at 1- and 2-year follow-up were analysed by means of generalized estimating equations.
Results: Levels of CML and CEL (as well as all other patients' characteristics) did not differ between groups at baseline. No significant changes were observed in CML and CEL over time in either group and there was no effect of treatment at any time-point. Mean differences between groups over time were -0.96 nM/mM lysine (95%CI: -3.43; 1.51) for CML and -0.10 nM/mM lysine (95%CI: -0.76; 0.56) for CEL (Figure 1).
Conclusion: Long-term irbesartan treatment does not influence plasma levels of the AGEs CML and CEL in patients with type 2 diabetes and micro-

albuminuria. These findings do not support the concept that ARBs inhibit the process of advanced glycation in humans.

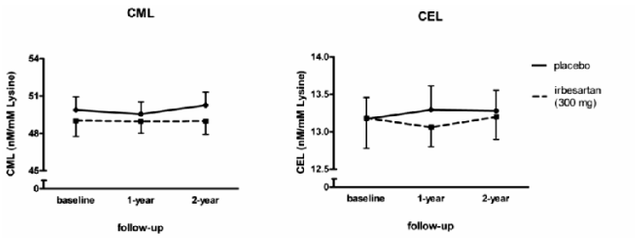

Figure 1. Means and standard errors of plasma levels of CML and CEL at baseline, 1-year and 2-year follow-up for the irbesartan treatment group and the placebo group

PS 119 Nephropathy - role of renal function

1204

Direct correlation between initial glomerular filtration rate and long-term urinary albumin excretion in patients with type 1 diabetes

S.L. Hyer[1], C. Soper[2], A. Tran[1], A. Rodin[1];
[1]Diabetes, St Helier University Hospital, Carhsalton, United Kingdom, [2]Diabetes, Mayday University Hospital, Croydon, United Kingdom.

Background: Increased glomerular filtration pressure and glomerular filtration rate (GFR) occur early in type 1 diabetes although their significance in the pathogenesis of diabetic nephropathy remains controversial.
Aims: To examine the relationship between initial GFR and urinary albumin excretion after at least 10 years follow-up.
Methods: 77 male patients (aged 18-42) with type 1 diabetes of short duration (4-8 years) and normal urinary albumin excretion (albumin: creatinine ratio (ACR)< 2.5 mg/mmol on 3 occasions) were studied at baseline using inulin clearance (ICL) to assess GFR. At baseline, 13 patients had evidence of glomerular hyperfiltration (ICL>145 ml/min/1.73m^2). Mean HbA1c: 8.3%. All patients were invited to attend a follow-up study after a median of 163 (151-168) months where they provided 3 consecutive early morning urine samples for ACR.
Results: Complete data collection was available for 12 patients; the others were either untraceable or declined to participate in the follow-up study. At follow-up, all were normotensive (mean BP: 127/75), with normal renal function; mean HbA1c 7.6%; eight patients were taking statins and 3 were on ACE-inhibitor drugs. One patient had developed overt microalbuminuria. A significant correlation was shown between baseline ICL and follow-up mean (log) ACR (r^2=0.4; p=0.028). Baseline and follow-up HbA1c were closely correlated (r^2=0.52; p=0.008). When HbA1c was entered as a covariate, the correlation between ICL and ACR just failed to achieve significance (p=0.055).
Conclusion: The results of this study support a link between GFR measured by inulin clearance and the development of nephropathy reflected by urinary albumin excretion. The relationship is, however, strongly influenced by the prevailing glycaemic control.

Background and aims: Albuminuria in the 'high-normal' range, is a predictor of cardiovascular morbidity and mortality. Which factors account for this increased risk and whether such a prediction is maintained also in the absence of a concomitant reduction of glomerular filtration rate (GFR) is unclear yet. The aim of the present study was to explore, in a large cohort of patients with type 2 diabetes (T2DM) with normoalbuminuria and no evidence of kidney impairment, the association between traditional cardiovascular risk factors and urinary albumin excretion.
Materials and methods: This was a cross-sectional study investigating 1148 (556M/592F) patients with T2DM, age 60.4 ± 10.1 yrs, duration of diabetes 10.5 ± 9.1 yrs, with normoalbuminuria [ACR 0.80 (0.01 - 3.49) mg/mmol] and estimated-GFR ≥ 60 ml/min/1.73m^2 (89.5 ± 20.8 ml/min/1.73m^2). Normoalbuminuria was defined if the albumin/creatinine ratio (ACR) was <2.5 in men and < 3.5 mg/mmol in women. Estimated-GFR was derived by serum creatinine.
Results: ACR significantly and independently correlated with gender (p=0.016), age (b=0.112, p=0.001), HbA1c (b=0.137, p <0.0001), BMI (b=0.106, p=0.036) and SBP (b=0.076, p=0.013). A gradual increase by tertiles of ACR in the proportion of patients with HbA1c ≥ 7% [269 (70.4%) vs 305 (79.6%) vs 313 (81.7%), p<0.0001], hypertension [282 (73.8%) vs 286 (74.6%) vs 322 (84.0%), p =0.020], Metabolic Syndrome [291 (76.1%) vs 298 (77.8%) vs 324 (84.5%), p=0.021] and retinopathy [83 (21.7%) vs 120 (31.3%) vs 128 (33.4%), p=0.001] was also observed.

Conclusion: Our data indicate that patients with T2DM and albuminuria in the high-normal range, even in the absence of GFR reduction, are characterized by the presence of several cardiovascular risk factors and suggest they may deserve a careful clinical follow-up. Prospective studies are needed to investigate whether a new threshold to define microalbuminuria and to be used as cut-off in the stratification of global cardiovascular risk is needed.

Association of renal function with anaemia in diabetic kidney disease

S.A. Martynov, M.V. Shestakova, Y.I. Suntsov, O.V. Maslova, I.I. Dedov;
Endocrinology Scientific Center, Moscow, Russian Federation.

Background and aims: Anemia is a common complication of chronic kidney disease (CKD) particularly in patients (pts) with diabetic kidney disease (DKD). In DKD anemia occurs early and is more severe than in non diabetic CKD. The aim of the study was to estimate the prevalence of anemia in diabetes mellitus (DM) pts with and without renal damage.
Materials and methods: A total 2015 DM type 1 (DM 1) (n=807; 40%) and type 2 (DM 2) (n=1208; 60%) pts were screened for presence of anemia. Their mean clinical data: age - 50,0±16,1 years, DM duration - 12,2±8,6 years, $HbA1_c$ - 8,7±2,0 %, hemoglobin (Hb) - 134,8±17,8 g/l. Mean glomerular filtration rate (GFR) was calculated using the MDRD formula - 107,6±39,8 ml/min/1,73 m^2, The 66.3% pts had arterial hypertension. Anemia was defined as Hb < 13.0 g/dl for men and Hb < 12.0 g/dl for women by the gender specific definition of WHO for pts without DKD and Hb < 13.5 g/dl for men and Hb <12.0 g/dl for women by the definition of anemia in CKD by National Kidney Foundation/Kidney Disease Outcome Quality Initiative (NKF/KDOQI) for pts with DKD. Evaluation of the distribution of anemia was based on 5 stages of CKD categories according NKF/KDOQI. Patients with GFR<15 ml/min/1,73 m^2 (5 stage of CKD) and treated by erythropoesis-stimulating agents were not included.
Results: The prevalence of anemia in DKD pts (n=971; 48.2%) was 32.4% compared to 13.8% in pts without renal damage (n=1044; 51.8%) (p<0.001). In DM 1 with DKD, the anemia prevalence was significantly higher than in DM 2 (41.9% and 23.7%, respectively (p<0.001)). Comparison of anemia prevalence based on pts gender did not find significant discrepancy in total group of DKD pts and pts DM 1 with DKD, except in pts DM 2 (male - 30.5% vs female - 21.9%, respictevely (p<0.05). The prevalence of anemia significantly increased in pts with evident renal injury and achieved to 47.1% in proteinuric pts (n=323), that greatly higher compared to pts with microalbuminuria - 25.7% (n=607) (p<0.001) and normoalbuminuria - 14.3% (n=1085) (p<0.001). Anemia prevalence significantly increased when the renal failure progresses (Table 1; *P<0.05; **P<0.01 between CKD 1 stage and other CKD stages). In DKD the Hb had strong association with GFR (R=0,41; p<0,001), DM duration (R=-0.27; p<0.001). Independent factors for Hb level by multiple logistic regression analysis were DM type - 1 (beta = -0.21), gender - male (beta = -0.30), albuminuria (beta = -0.10), hypertension (beta = -0.08) and GFR (beta = 0.33) (p<0.001).
Conclusion: Anemia is a prevalent finding in pts with DKD, especially in DM 1. In half of DM 1 pts and in one-of third type DM 2 pts anemia develops when the mild decrease of GFR (60-89 ml/min/1,73 m^2). The prevalence of anemia in DKD is clearly related to the degree of albuminuria and decreasing of renal function.

Anemia prevalence in diabetic kidney disease patients according to CKD stages (%)

	CKD 1 stage (GFR ≥ 90 ml/mi/1,73 m^2), n=523	CKD 2 stage (GFR 60-89 ml/min/1,73 m^2), n=231	CKD 3 stage (GFR 30-59 ml/min/1,73 m^2), n=169	CKD 4 stage (GFR 15-30 ml/min/1,73 m^2), n=48
All patients (n=971)	21.1	35.9**	46.7**	87.5**
Type 1 (n=403)	25.5	46.5**	66.1**	85.3**
Type 2 (n=568)	18.2	27*	36.4**	92.8**

1207

Renal perfusion is reduced in apparently uncomplicated type 1 diabetic patients

S.M. Marshall[1], R. Taylor[2], P.E. Thelwall[2];
[1]ICM, Newcastle University, [2]Newcastle Magnetic Resonance Centre, Newcastle University, United Kingdom.

Background and aims: Magnetic resonance imaging (MRI) offers novel, non-invasive techniques for investigation of diabetic nephropathy. We assessed renal perfusion in control subjects and Type 1 diabetic patients with and without microalbuminuria.
Materials and methods: 8 Type 1 diabetic patients (T1C) (age 40.1±6.7 years, duration diabetes 28.4±6.2 years, eGFR 76.1±8.24 ml/min/1.73 m^2, albumin: creatinine ratio (ACR) persistently <2.5 mg/mmol, BP <130/80 mmHg on no treatment, no or minimal background retinopathy), 8 Type 1 diabetic patients with microalbuminuria (T1M) (ACR persistently >5.0 mg/mmol), eGFR 78.1±9.9 ml/min/1.73 m^2 ,age 41.2±7.3 years, duration diabetes 27.3±5.6 years, all with significnat retinopathy, and seven healthy control subjects (C), age 39.0±7.9 years, on no medication, participated. Six T1M participants were studied on (T1Mon) and after 4 weeks off (T1Moff) RAAS inhibition. Blood pressure (BP) control off RAAS inhibition was maintained by non-RAAS agents. Studies were performed fasting. Blood glucose was maintained at 4.0-6.0 mmol/l in the diabetic subjects by IV insulin infusion. Phase-contrast angiography was performed to measure renal artery flux over the cardiac cycle before and after water loading (20 ml/kg body weight), when urine flow >8 ml/min.
Results: Renal artery flow rate (RAF), corrected for body surface area and pulse rate, was higher in the control subjects (791±253 ml/min/1.73 m^2 body surface area) compared to T1C (622±128) and T1Moff (580±188; ANOVA p=0.05), with no significant difference between T1C and T1Moff. There was no change with water loading. RAF (587±118 vs 580±188 ml/min/1.73m^2) and eGFR (71.1±10.4 vs 78.1±9.9 ml/min/1.73m^2) were similar in T1Mon and T1Moff. RAF correlated with eGFR in all diabetic patients (r=0.59, p=0.031), and in T1C (r=0.84, p=0.01) but not in T1Mon (r=0.39, p=0.52) or T1Moff (r=0.008, p=0.99).
Conclusion: In longstanding apparently otherwise healthy Type 1 diabetic patients with clinically normal renal function, renal perfusion is decreased to a level similar to that in Type 1 microalbuminuric patients. Perfusion is unaltered by water diuresis or RAAS blockade. The different relationships between eGFR and RAF in the normo- and micro-albuminuric patients suggest different haemodynamic changes. The reasons for reduced perfusion are unclear.

Determinants of decline in glomerular filtration rate in association with progression of albuminuria in type 2 diabetes

H. Yokoyama[1], S. Kannno[1], S. Takahashi[1], D. Yamada[1], J. Honjo[1,2], H. Sone[1,3], M. Haneda[2];
[1]Internal Medicine, Jiyugaoka Clinic, Obihiro, [2]Department of Medicine, Asahikawa Medical College, [3]Department of Internal Medicine, University of Tsukuba Institute of Clinical Medicine, Japan.

Background and aims: Some normoalbuminuric type 2 diabetic subjects have a reduced glomerular filtration rate (GFR), but common and independent risks for GFR decline and albuminuria progression remain unclear.
Materials and methods: An observational 4-year cohort study was performed on 1,002 subjects with preserved GFR (699 normoalbuminuric), and the predictive value of baseline variables on the GFR slope was investigated. GFR decliner and albuminuria progressor were defined as a GFR slope <-4.0 %/year and changes in the geometric mean in urinary albumin from baseline to follow-up >150%, respectively.
Results: Multiple linear regression analysis indicated that GFR slope was predicted by baseline variables of urinary albumin, GFR, HbA_{1C}, systolic blood pressure, plasma total protein, and retinopathy. The effects of these risks appeared variable according to whether individuals had high or low urinary albumin and GFR levels. Subjects cross-classified according to GFR decliner/albuminuria progressor consisted of 51%(-/-), 13%(-/+), 28%(+/-), and 8%(+/+). Common risks for GFR decline and albuminuria progression were retinopathy, neuropathy, HbA_{1C}, and urinary albumin. Independent significant risks for GFR decline were baseline GFR, systolic blood pressure, total protein, and hypertension. Proportion of progression to albuminuria was similar between GFR decliners and non-decliners.

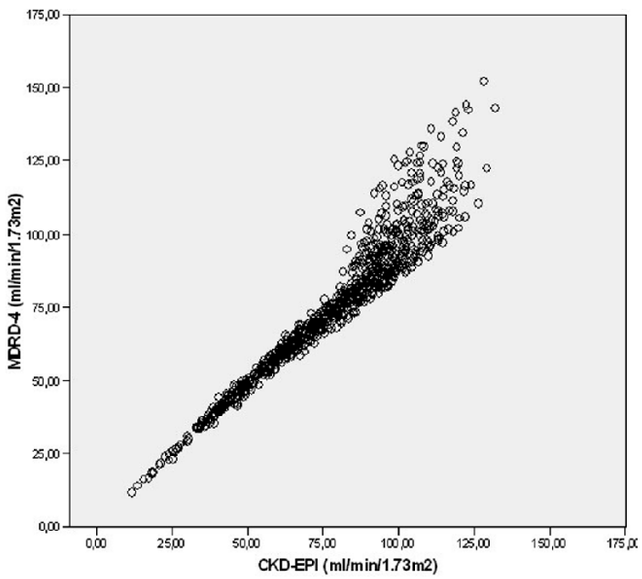
Conclusion: In type 2 diabetes, the GFR slope was predicted and affected at various stages by multiple factors. Isolated GFR decline and albuminuria progression are not rare, and common and independent risk factors predictive for GFR decline and albuminuria progression exist.

1209

The chronic kidney disease collaboration equation: not of additional value compared to the modification of diet in renal disease equation in diabetic patients

I. Drion[1], H. Joosten[1,2], L.J. Ubink-Veltmaat[3], L.G. Lieverse[4], K.J.J. Van Hateren[1], K.H. Groenier[5], N. Kleefstra[1,6], H.J.G. Bilo[7,1];
[1]Diabetes Center, Zwolle, [2]Internal Medicine, University Medical Center Groningen, [3]General practice 't Veen, Hattem, [4]Internal medicine, Maxima Medical Center, Eindhoven,[5]General practice, University Medical Center Groningen, [6]Langerhans Medical Research Group, Zwolle, [7]University Medical Center Groningen, Netherlands.

Background and aims: Equations to estimate the glomerular filtration rate (GFR) are routinely used to assess kidney function. Due to the systematic underestimation and limited precision of the current prediction equations, especially when GFR is ≥60ml/min/1.73m^2, a new prediction equation was developed with the aim to reduce these problems: the chronic kidney disease collaboration equation (CKD-EPI). We aimed to compare the outcomes of the CKD-EPI and MDRD-4 equation with the creatinine clearance (CrCl) in a cohort of diabetic adults.
Materials and methods: In this retrospective cohort study of 844 diabetic outpatients, the MDRD-4 and the CKD-EPI were calculated and compared by means of correlation to the 24 hour CrCl, 'the golden standard of daily practice'. MDRD-4 was correlated to CKD-EPI to assess in which clearance ranges differences between the two prediction equations were present. Bias and precision were evaluated to determine the degree of reliability and consistency of both equations. Furthermore, the percentage of subjects having an under- or overestimated kidney function was calculated.



Results: Both the MDRD-4 and the CKD-EPI equation were similarly, though only moderately correlated with CrCl (r=0.69 and r=0.73, respectively). The MDRD-4 showed a high correlation with the CKD-EPI (r=0.98) for patients with an eGFR ≤90ml/min. The correlation decreased to r=0.46 for patients with an eGFR >90ml/min (figure 1). Mean overall bias (SD) of the MDRD-4 and CKD-EPI compared to CrCl were -32.8 (±32.3) ml/min/(1.73m^2) and -33.3 (±32.6) ml/min/(1.73m^2), respectively (p=0.2). Mean bias (SD) between CrCl and MDRD-4 / CKD-EPI in the clearance category >60ml/min were -37.1 (±31.5) ml/min (1.73m^2) / -37.8 (±31.5) ml/min (1.73m^2) respectively (p=0.14). In the different KDOQI stages, the differences between MDRD-4 and CKD-EPI were small and non-significant. When using either CKD-EPI or MDRD-4 for identifying patients with CKD, only approximately 50% of the patients were correctly classified, even when a dispersion of 30% compared to CrCl was accepted.
Conclusion: The CKD-EPI appeared to have no additional value compared to the MDRD-4 when used in a cohort of diabetic patients with a relative preserved renal function. Our data do not support adjustment of current guidelines towards the use of this new prediction equation.

1210

Estimation of glomerular filtration rate in patients with diabetes mellitus type 2: comparison of CKD EPI equation and cystatin C-based formula

T. Didangelos[1], A. Ntemka[1], F. Iliadis[1], A. Makedou[2], C. Margaritidis[1], E. Papanastasiou[3], K. Makedou[2], A. Gotzamani-Psarakou[3], D. Grekas[1];
[1]Diabetes Division,1st Propeudetic Department of Internal Medicine, [2]Laboratory of Lipids, 2nd Paediadtric Department, [3]Laboratory of Nuclear Medicine, ''AHEPA'' Hospital of Thessaloniki, Aristotle University of Thessaloniki, Greece.

Background and aims: The estimation of Glomerular Filtration Rate (GFR) by the Modification of Diet in Renal Disease (MDRD) equation, which is based on serum creatinine (Scr), has recognised limitations. A new equation was proposed by the Chronic Kidney Disease Epidemiology Collaboration (CKD EPI) to improve estimation of GFR. The CKD-EPI equation showed improved performance compared to the MDRD equation. Moreover, serum cystatin C (ScysC) has been proposed as a potential replacement of Scr in GFR estimation. We compared the CKD-EPI equation to a Scyst based formula for GFR estimation in patients with type 2 diabetes.
Materials and methods: We studied 368 Caucasians participants with type 2 diabetes, 168 (45.7%) men, with [mean (SD)]: age 65 (10) years, BMI 30.7(5.1) Kg/m^2, HbA1c 7.0 (1.5)%. GFR was measured using plasma clearance of 51Cr-EDTA (mGFR). In parallel, GFR was estimated twice, using the CKD-EPI equation [If female and Scr ≤ 0.7 mg/dl, CKD-EPIGFR = $144 \times (Scr/0.7)^{-0.329} \times (0.993)^{Age}$ - if female and Scr >0.7 mg/dl, CKD-EPIGFR = $144 \times (Scr/0.7)^{-1.209} \times (0.993)^{Age}$ - if male and Scr ≤0.9 mg/dl, CKD-EPIGFR = $141 \times (Scr/0.9)^{-0.411} \times (0.993)^{Age}$ - if male and Scr >0.9 mg/dl, CKD-EPIGFR= $141 \times (Scr/0.9)^{-1.209} \times (0.993)^{Age}$] and the Stevens equation which is based on ScystC [cystCGFR: $127.7 / (ScystC^{1.17}) \times (age^{-0.13}) \times (0.91$ if female)]. Estimated GFR results were compared with isotopic GFR by means of two-tailed, paired t tests and by Levene's test for equality of variance. Bland-Altman plots were obtained.
Results: MGFR was 72.0 (22.3) ml/min per 1.73 m^2, CKD-EPIGFR was 83.0 (20.3) ml/min per 1.73 m^2 (p<0.05 for difference from mGFR) and cystCGFR was 72.5 (27.9) ml/min per 1.73 m^2 (NS difference between mGFR and cystCGFR). Bland-Altman plots showed that 95.1% and 93.9% of estimations for CKD-EPIGFR and cystCGFR respectively, lie within the ± 1.96SD of the mean difference. Bias (mean difference between estimated GFR and mGFR) was 10.5 and 0.45 ml/min per 1.73 m^2 for CKD-EPIGFR and cystCGFR respectively (p<0.05 for difference in bias between CKD-EPIGFR and cystCGFR). Precision (SD of the bias) was 13.8 and 21.96 ml/min per 1.73 m^2 for CKD-EPIGFR and cystCGFR respectively (p<0.05 for difference in precision between CKD-EPIGFR and cystCGFR). Accuracy 10% (proportion of estimated GFR results within 10% of mGFR) was 34.8% and 33.2% for CKD-EPIGFR and cystCGFR respectively (NS difference in accuracy 10% between CKD-EPIGFR and cystCGFR). Accuracy 30% (proportion of estimated GFR results within 30% of mGFR) was 72.4% and 72.6% for CKD-EPIGFR and cystCGFR respectively (NS difference in accuracy 30% between CKD-EPIGFR and cystCGFR).
Conclusion: Stevens cystatin C based formula was less biased than and CKD-EPI equation. On the other hand CKD-EPI equation was more precise and presented higher agreement with measured GFR. These results support the superiority of CKD-EPI equation over Stevens cystatin C based formula for estimation of GFR in patients with type 2 diabetes.

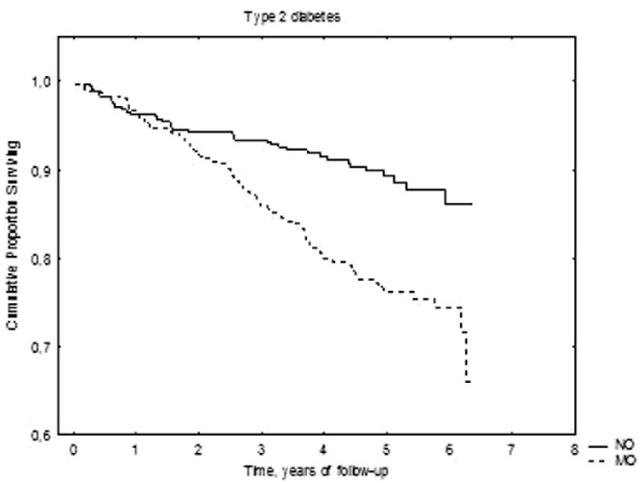
Orosomucoid excretion in urine predicts mortality in type 1 and type 2 diabetes

M.S. Christiansen[1], J. Mølvig[1], E. Magid[2];
[1]Department of Internal medicine, Amager Hospital, Copenhagen,
[2]Department of Clinical Biochemistry, Amager Hospital, Copenhagen, Denmark.

Background and aims: Increased mortality compared to the background population is still a problem of serious concern in diabetes mellitus. Previously we have shown that increased urinary excretion of the inflammatory protein orosomucoid (UOER) independently predicts cardiovascular mortality in patients with type 2 diabetes (T2DM). The evaluation was in a dichotomous comparison. The aim of the present study was to evaluate the predictive value of UOER in a continuous scale on mortality in patients with type 1 (T1DM) and T2DM.
Materials and methods: Patients with diabetes were consecutively included from the outpatient clinic at Amager Hospital provided they had negative urine sticks. Urine samples were analysed for orosomucoid and albumin by immunoturbidimetry. Cut-off value for increased UOER was 2.04 μg/min. Survival analyses were done using Kaplan-Meier survival curves and compared by log-rank test. Cox proportional hazards regression analysis with backward stepwise regression was used for multivariate analysis.
Results: 195 patients with T1DM and 706 patients with T2DM were followed for mean (SD) period of 4.6 (1.3) years. For T1DM mean age was 42 (14) years, HbA1c was 8.6 (1.9) %, median (range) duration of diabetes was 10 (0-44) years and median UOER was 1.00 (0.02-350) μg/min. For T2DM mean age was 59 (11) years, HbA1c was 8.2 (1.8) %, median duration of diabetes was 6 (0-44) years and median UOER was 2.05 (0.03-225) μg/min. Eight patients with T1DM and 120 patients with T2DM died in the follow-up period. In T1DM there was a significant difference in survival between patients with normal (NO) versus increased (MO) UOER ($p<0.006$). There was also a highly significant difference in survival in T2DM ($p<0.0003$) (figure). Using multivariate regression analysis we found that increased UOER (μg/min) (OR: 1.12 (95% CI: 1.04-1.20); $p< 0.003$), age (years) (1.37 (1.27-1.46); $p< 0.00001$) and male sex vs. female (1.12 (1.04-1.20); $p< 0.002$) independently predicted mortality in T2DM. The analyses were adjusted for BMI, HbA1c and systolic blood pressure. When albumin was included in the analysis UOER was not a significant predictor of mortality in T2DM. In a dichotomous comparison UOER was still an independent predictor of mortality in T2DM: NO vs. MO: (1.12 (1.04-1.20); $p< 0.004$), age (1.35 (1.26-1.45); $p< 0.00001$) and sex (1.10 (1.02-1.18); $p< 0.02$) independently predicted mortality. For T1DM: NO vs. MO (1.24 (1.06-1.44; $p< 0.008$)), age (1.18 (1.01-1.37); $p< 0.04$) and BMI (0.83 (0.72-0.97); $p< 0.02$) independently predicted mortality. The latter 2 analyses were adjusted for BMI, HbA1c, systolic blood pressure and microalbuminuria. In a dichotomous comparison microalbuminuria was not an independent predictor of mortality in T1DM or T2DM.
Conclusion: For the first time we have shown that UOER independently predicts mortality in patients with T1DM and confirmed the results in T2DM in a dichotomous comparison. In a continuous scale albuminuria was superior to UOER in T2DM.



1212

Microalbuminuria but not reduced GFR is a marker of subclinical atherosclerosis and arterial stiffness in type 2 diabetes

P. Sjöblom[1], J. Engvall[2], T. Länne[1], F. Nyström[1], C. Östgren[1];
[1]Department of Medical and Health Sciences, Linköping University,
[2]Department of Clinical Physiology, Linköping University Hospital, Sweden.

Background and aims: Microlbuminuria is a strong predictor for cardiovascular disease in patients with type 2 diabetes. However, the role of reduced renal function, expressed as an estimated Glomerular Filtration Rate (GFR) as a risk assessment tool for macrovascular complications is unclear. The aim of this study was to explore the associations between GFR vs. microulbuminuria and subclinical organ damage in patients with type 2 diabetes.
Materials and methods: Baseline data were analysed from 706 patients who participated in the Cardiovascular Risk factors in Patients with Diabetes - a Prospective study in Primary care (CARDIPP). The Patients, aged 55-65 years, were consecutively recruited 2005-2008 from 22 primary health care centres in Sweden. Urine and blood samples for laboratory analyses were taken in the morning following 10 hours fasting. Presence of microalbuminuria (alb) was defined as u-albumin/creatinine ratio (ACR) >3.0 mg/mmol. GFR was calculated by use of the MDRD formula and reduced renal function defined as < 60 ml/min/1,73m^2. Office blood pressure (BP) was measured by dedicated nurses and 24h-ambulatory BP was also performed. The carotid intima-media thickness (IMT) was determined by ultrasonography. Arterial stiffness was evaluated by pulse wave velocity (PWV) measured as transit time between the carotid and femoral arterial pulse waves. Left ventricular mass was measured echocardiographically, corrected for body surface area expressed as left ventricular mass index (LVMI)
Results: Patients with alb had increased IMT (0.78 vs 0.73 mm), PWV (11.5 vs 10.1 m/s) and LVMI (134.4 vs 118.3 g/m^2) compared to subjects with no alb. The table shows the results further divided and analysed for significance. There were no statistically significant differences in IMT, PWV or LVMI between patients with reduced renal function according to GFR compared to subjects with GFR > 60 ml/min/1.73m^2.
Conclusion: We conclude that microalbuminuria defined as ACR, but not impaired renal function according to GFR, is a marker for subclinical organ damage in terms of atherosclerosis, arterial stiffness and increased left ventricular mass in patients with type 2 diabetes.

Table

Albuminuria is associated with angiographically determined coronary atherosclerosis both in patients with type 2 diabetes and in non-diabetic individuals

C. Boehnel[1,2], P. Rein[1,2], C.H. Saely[1,2], A. Vonbank[1,2], S. Beer[1,2], V. Jankovic[1,2], J. Breuss[1,2], L. Risch[1], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Prinicpality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Albuminuria is associated with atherothrombotic events and all-cause mortality in patients with diabetes as well as in non-diabetic individuals. In the present study we aimed at investigating whether albuminuria is associated with directly visualised atherosclerosis in the same manner.

Materials and methods: We enrolled 909 consecutive Caucasian patients, including 226 patients with type 2 diabetes (T2DM) and 683 non-diabetic subjects who were referred to coronary angiography for the evaluation of stable coronary artery disease (CAD). Elevated urinary albumin excretion (UAE) was defined as an urinary albumin to creatinine ratio (ACR) ≥30 μg/mg; significant CAD was diagnosed in the presence of coronary artery lumen narrowing ≥50%.
Results: The prevalence of significant CAD was significantly higher in patients with an elevated UAE than in those with normal UAE (65.9 vs. 51.4%; p <0.001). Logistic regression analysis adjusting for age, gender, smoking, hypertension, LDL cholesterol, HDL cholesterol, CRP, BMI, use of ace/angiotensin II antagonists, aspirin and statins, as well as for the gomerular filtration rate (eGFR) and for T2DM confirmed elevated UAE as a significant predictor of angiographically determined CAD (OR=1.68 [1.15-2.44]; p=0.007). Similarly, the ACR was significantly associated with significant CAD when treated as a continuous variable (standardized adjusted OR=1.45 [1.13-1.86]; p=0.004). The prevalence of elevated UAE was significantly higher in patients with T2DM than in non-diabetic patients (38.9 vs. 18.0%; p <0.001). Like in the total study cohort, the prevalence of significant CAD was higher in patients with elevated UAE than in those with normal UAE out both in patients with diabetes (75.0 vs. 60.9%; p = 0.028) and in those without diabetes (59.3 vs. 49.1; p = 0.040). Concordantly, the ACR proved significantly predictive of significant CAD both in patients with T2DM (1.66 [1.01 - 2.74]; p = 0.045) and in patients without diabetes (1.42 [1.05 - 1.92]; p = 0.023) in a fully adjusted model.
Conclusion: In conclusion, an elevated UAE is strongly associated with angiographically determined coronary atherosclerosis both in patients with T2DM and in non-diabetic patients, independent of conventional cardiovascular risk factors and of the eGFR.

Seasonal variations of urinary albumin/creatinine ratio in subjects with type 2 diabetes and nephropathy

Y. Wada[1], Y. Hamamoto[1], Y. Iwasaki[1], J. Fujikawa[2], S. Honjo[1], Y. Kawasaki[1], K. Mori[1], H. Ikeda[3], K. Nomura[4], H. Koshiyama[1];
[1]Center for Diabetes and Endocrinology, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, [2]Department of Laboratory Medicine, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, [3]Ikeda Hospital, Amagasaki, [4]Division of Diabetes, Metabolism and Endocrinology, Kobe University Graduate School of Medicine, Japan.

Background and aims: It has been recognized that blood pressure shows a seasonal variation. There have been some reports about seasonal change of glycemic control and onset of diabetes. But it remains unknown whether diabetic nephropathy may show a seasonal variation in relation to blood pressure. In the present study, we investigated whether there may be a seasonal change in albumin/creatinine ratio (ACR).
Materials and methods: A total of 430 subjects (male : n=275, female : n=155) with type 2 diabetes and early nephropathy were included, whose mean age was 64.8±0.8 SE years. Those who had advanced stage of nephropathy with increased creatinine were excluded. Data were obtained from 2006 to 2009 at each time of the visit and one-way ANOVA (SPSS-II for windows) was used to determine the presence of seasonal variation.
Results: There were significant seasonal variations in ACR, systolic blood pressure and A1C. The mean ACR was higher in winter (December - February ; 72.8±4.4mg/gCr) than that in summer (June - August ; 54.6±3.4mg/gCr) (p=0.001). The mean systolic blood pressure was higher in winter (136±0.68mmHg) than that in summer (133±0.68mmHg) (p<0.001). The ACR variation showed similar curve to that of the seasonal variation of systolic blood pressure. In contrast, A1C did not show similar curve to that of ACR or systolic blood pressure. The mean A1C was higher in spring (March - May ; 7.39±0.03 %) than that in fall (September - November ; 7.16±0.03 %) (p<0.001). No significant seasonal variation was observed in estimated glomerular filtration rate and diastolic blood pressure.
Conclusion: Our results suggest that there is a hitherto unknown seasonal variation in ACR, and that it may be necessary to consider the seasonal change of ACR especially when we perform intervention study of the nephropathy.

1215

Factors associating with renal interstitial fibrosis in type 2 diabetics with renal artery stenosis and in type 1 and 2 diabetics with diabetic nepropathy

K.O. Kurumova, M. Shamkhalova, I. Klefortova, M.V. Shestakova, I. Sitkin, A. Ilin, M. Arbuzova, N. Goncharov, G. Katsaya, S. Saveleva;
Diabetic Nephropathy, Endocrinology Research Cenre, Moscow, Russian Federation.

Aims: to estimate renal interstitial fibrosis and endothelial dysfunctions factors in type 2 diabetics patients (T2DP) with renal artery stenosis or diabetic nephropathy (DN) and in type 1 diabetics with DN.
Methods: We studied 33 T2DP without renal pathology (I group), 33 T2DP with renal artery stenosis (II group), 24 T2DP with DN (III group) and 30 diabetic type 1 patients with DN (IV group). Patients with T2DP were invited to undergo multispiral computer tomography or selective angiography of renal arteries to define the presence of renal artery stenosis (renal artery stenosis more than 60%). We have measured following parameters in blood: transforming growth factor (TGF - β 1), monocyte chemotactic peptide-1 (MCP-1), regulated on activation normal T-cell expressed and secreted (RANTES), matrix metalloproteinase 9 (MMP - 9),vascular endothelial growth factor (VEGF), vascular cell adhesion molecule (VCAM-1), inhibitor activator of plasminogen (IAP-1), asymmetric dimethylarginine (ADMA), factor von Willebrand (FW), homocystein (HCYST) were measured. The control group included normotensive persons of more than 45 years without diabetes (n=20). Glomerular filtration rate (GFR) was calculated by the MDRD equation.
Results: Studied parameters were higher in groups with renal pathology than in group I (Table 1).

Studied parameters in groups Table 1

Parameter	I group n=33	II group n=33	III group n=24	IV group n=30
TGF - β 1 ng/ml	40,6 [8,6; 81]	121 [11,9; 78]***	80,6 [31,7; 128]**	65 [18,3; 104]***

ADMA mkmol/l	1,42 [0,02; 1,46]	14,1 [0,02; 1,4]**	1,7 [0,4; 1,6]	-
VEGF pg/ml	182 [49; 263]	284 [140; 386]**	203 [61,9; 223]	184 [81; 259]

Results are Me[25%;75%]
* - p <0,05 ** - p<0,01 *** - p<0,0001 vs group I

In groups with renal pathology TGF - β 1, MCP-1, RANTES, MMP - 9, HCYST, were negative correlated with GFR and were positive correlated with albuminuria.
Conclusion: DN in type 1 and 2 patients and renal artery stenosis in T2DP were associated with significant increase of mediators of fibrosis and endothelial dysfunctions factors which is known to have a predictive role in the development of the tubulointerstitial expansion and reduction of renal function.

Urinary proteomics for early diagnosis in diabetic nephropathy

P. Rossing[1], P. Zürbig[2], S. Panagiotopoulos[3], S.E. Nielsen[1], P. Hovind[1], R.J. Maclsaac[3], H. Mischak[2], G. Jerums[3], H.-H. Parving[4,5];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Mosaiques-diagnostics GMBH, Hannover, Germany, [3]Austin Healths, Melbourne, Australia, [4]Endocrinology, Rigshospitalet, University of Copenhagen, Denmark, [5]Faculty of Health Sciences, University of Aarhus, Denmark.

Background and aims: Diabetic nephropathy may be detectable even at early stages in the urinary proteome. In this study we present recent data indicating that urinary proteome analysis is a valuable tool for early and sensitive

detection of diabetes-associated patho-physiological changes, assessment of disease progression and monitoring of therapy success.
Materials and methods: High-resolution capillary-electrophoresis coupled to time-of-flight mass-spectrometry (CE-MS) was used to profile the low-molecular-weight proteome in urine of diabetic patients collected in longitudinal trials for up to 15 years at two different clinical centers in Denmark and Australia.
Results: When applying previously defined biomarker patterns for chronic kidney disease onto the data obtained from urine samples of normoalbuminuric subjects, we could demonstrate that these biomarkers enabled prediction of development of macroalbuminuria with an AUC=0.92 for a period of 3-4 years. One of the hallmarks of diabetes and associated complications appears to be the increase in extracellular matrix (ECM) and the release of its components, most notably collagen. This process appears to be in part due to reduced proteolysis and is reflected at a very early stage by the decrease in urinary collagen fragments. Assessment of these results in a much higher accuracy of predicting DN than clinical parameters like urinary albumin or serum creatinine.
Conclusion: Urinary proteome analysis enables the non-invasive assessment of diabetic kidney disease at an early stage via determination of specific collagen fragments, opening an avenue towards targeted therapeutic intervention. Further, prognosis of progression towards DN will help targeting therapeutic intervention, ideally before irreversible damage has occurred.

1217

Adiponectin is differently associated with nephropathy in type 1 and type 2 diabetes

S. Ljubic[1], B. Novak[1], A. Jazbec[2], A. Piljac[1], T. Kerum[1], M. Vucic Lovrencic[1];
[1]Vuk Vrhovac University Clinic, [2]University of Zagreb, Croatia.

Background and aims: The aim of this study was to compare the relation between adiponectin and nephropathy in type 1 and type 2 diabetes.
Materials and methods: ApN, C-reactive protein (CRP), fibrinogen (FIB), homocysteine (HCY), lipoprotein(a) [Lp(a)], creatinine clearance (CrCl), creatinine, fasting (fPG) and postprandial plasma glucose (ppPG), glycated haemoglobin (A1c), blood pressure (BP), liver function, lipids, ferritin, uric acid (UA), creatine phosphokinase and leucocyte count (WBC) were determined in 164 patients with type 1 (DM1) and type 2 diabetes (DM2). The patients were assigned to subgroups based on their 24-h albumin excretion rate (AER) [<30 (NA), 30-300 (MI), >300 (MA)] and CrCl (normal >0.83 mL/sec for women and >1.17 mL/sec for men (CrCl1)). Differences between types of DM were tested using Student t test or Mann Whitney test if assumption of homogeneity of variance was not met. Differences between ApN according to AER and CrCl were tested using factorial analysis of variance.
Results: Statistically significant differences were found among ApN values according to AER (F=8,45, df=2, p<0.001) in DM1 (NA=12.37±6.62, MI=21.38±7.98 and MA=31.85±18.05) and DM2 (NA=9.05±5.63, MI=7.46±4.58 and MA=5.26±3.3). A statistically significant difference in ApN between the types of DM (F=73.402, df=1; p<0.001), and an interaction between DM type and AER (F=18.12, df=2; p<0.001) were also observed. DM1 had significantly higher ApN than DM2. Significant within-group differences for ApN were found in DM1 between the NA and MI, and the NA and MA subgroups using Tukey post hoc test, while between-group differences in ApN were found in the MI and MA subgroups of DM1 and DM2. In a model for ApN as a dependent variable and the type of DM, CrCl and interaction DM type and CrCl as factors, a statistically significant difference was found for all analysed factors. ApN was found to be higher in CrCl2 than in CrCl1 (F=12.7, df=1, p<0.001) in both types of diabetes (DM1: CrCl1=13.9±7.93 vs. CrCL2=23±12.8 and DM2: CrCl1=7.63±4.76 vs. CrCl2=9.86±6.25). Post hoc test showed that ApN was significantly increased in both CrCl subgroups of DM1 as compared to DM2. In a model for Lp(a) as a dependent variable and the type of DM (F=0.82; df=1; p=0.37), AER (F=0.21, df=2, p=0.81) and interaction between DM type and AER (F=0.06; df=2; p=0.93) as factors, there were no statistically significant differences. After stepwise regression in DM1 for ApN, the best model (R^2=0.9002) included CrCl, BMI, LDL, WBC, CRP and age, whereas in DM2 the best model (R^2=0.2882) included ppPG, LDL, and UA. In DM1 ApN correlated significantly (p<0.05) with HCY (r=0.57), CrCL (r=-0.61), AER (r=0.61) and creatinine (r=0.40), and in DM2 with HCY (r=0.25), CrCl (r=-0.22), creatinine (r=0.20) and diastolic BP (r=-0.19). ApN and HDL were significantly increased (p<0.001) in DM1, whereas CRP (p=0.04), FIB (p<0.001), HCY (p<0.001) and gamma-glutamyl-transpeptidase (p<0.05) were significantly increased in DM2.
Conclusion: ApN was increased in both DM1 and DM2 in the subgroups with decreased CrCl, but with a different albuminuria-related behaviour, showing an increase with a progression of albuminuria in DM1, and a decrease with a progression of albuminuria in DM2. Other inflammatory markers were decreased in DM1. The interaction between renal insufficiency and albumin loss appears to significantly affect ApN level, which is consistent with different courses of nephropathy in DM1 and DM2.

The expression of pigment epithelium-derived factors, matrix metalloproteinase-2 and transforming growth factor-β_1 and the effects of rosiglitazone in diabetic rat kidney

L.-X. Tan, Z.-J. Wang;
Endocrinology, Hebei Medical University, Shijiazhuang, China.

Background and aims: To investigate the expressions of pigment epithelium- derived factor, matrix metalloproteinase-2 and transforming growth factor-β_1 in the kidney of diabetic rats and the effects of rosiglitazone on such changes.
Materials and methods: 45 male SD rats were randomly divided into normal group(NC), diebetic control group(DC) and rosiglitazone treated group(DR), with 15 respectively. After 12 weeks, kidney mass/body mass, 24-hour urinary albumin excretion (UAE), serum creatinine(Scr), blood ureanitrogen (BUN) of every group were measured and the expression of PEDF, MMP-2 and TGF-β_1 in the kidney were determined by immunohisto- chemistry and RT-PCR methods.
Results: (1)KI, BUN, Scr, UAE, TG in DC group were higher than NC group, but decreased in DR group compared with DC group, the differences were statistically significant. (2) Immunohistochemistry showed that renal PEDF, MMP-2 expression in DC and DR group of were lower than NC group (P <0.01), while increased in DR group compared with DC group (P <0.01); the expression of TGF-β1 in DC and DR group were higher than NC group (P <0.01), while TGF-β1 expression in DR group decreased compared with DC group (P <0.01). (3)RT-PCR analysis showed that rosiglitazone can enhance the expression of PEDF mRNA in the kidney, the differences were statistically significant. (4)Correlation analysis showed that there was a negative correlation between the protain expression levels of PEDF or MMP-2 and TGF-β_1 in the kindey of diabetic rats (r=-0.964,P<0.01;r=-0.916,P<0.05). The protein expression levels of PEDF and MMP-2 showed a positive correlation in the kindey of these rats(r = 0.827,P <0.01).
Conclusion: Renoprotection of rosiglitazone on diabetic rats may be mediated through increasing the expression of PEDF and MMP-2 and decreasing the expression of TGF-β_1.

Abnormalities of the OPG/RANKL axis in progressive kidney failure: the variable influence of diabetes

D.K. Singh[1], P. Winocour[2], B. Summerhayes[2], A. Viljoen[3], G. Sivakumar[3], K. Farrington[4];
[1]Diabetes and Renal, Lister Hospital, Stevenage, [2]Diabetes and Endocrinology, QEII Hospital, Welwyn Garden City, [3]Biochemistry, Lister Hospital, Stevenage, [4]Renal Unit, Lister Hospital, Stevenage, United Kingdom.

Background and aims: The high prevalence of cardiovascular disease and vascular calcification in chronic kidney disease (CKD) is associated with both traditional and uremic-specific risk factors. These include hyperphosphatemia, high calcium x phosphate product, chronic inflammation, dyslipidemia and other dialysis-related factors. Recently the role of osteoprotegerin (OPG) and receptor activator of nuclear factor kappa-β-ligand (RANKL) in bone and vascular adaptations has become apparent. This study was designed to investigate the influence of kidney failure on this axis in diabetic and non diabetic subjects.
Materials and methods: Seventy patients were studied - 20 with Stage 3 CKD (CKD_{Mod}), 20 with Stage 4 and 5 CKD (CKD_{Adv}) and 30 on Haemodialysis (CKD_{HD}). Each groups had equal number of diabetics and non-diabetics. Serum OPG and RANKL were measured along with parameters reflecting renal function and mineral metabolism.
Results: Mean OPG levels in the CKD_{HD} group were higher than in the CKD_{Adv} group (p< 0.001) and the CKD_{Mod} group (p<0.001) (9.8 vs. 5.8 vs 5.4

respectively). There were no differences in RANKL levels across the groups. The OPG/RANKL ratio was significantly different across the groups (p = 0.038). Median OPG/RANKL ratio was higher in the CKD_{HD} group than in the CKD_{Adv} group (p = 0.016) and the CKD_{Mod} group (p = 0.066) (109 vs. 45: vs. 61 respectively). In the CKD_{Mod} group OPG levels were higher in diabetic patients than in non-diabetics (6.1 vs. 4.5 pmol/l: p = 0.032). The same was true in the CKD_{Adv} group (6.7 vs. 4.6 pmol/l: p = 0.032). However, in the CKD_{HD} group, diabetics had lower OPG levels (8.6 vs. 10.9 pmol/l), though this difference did not reach statistical significant (p = 0.079).
Conclusion: OPG is secreted by endothelial cells and tends to protect against VC. Rising OPG levels in progressive kidney failure imply mobilisation of protective adaptations to the increased calcific stimulus generated by falling kidney function. The higher OPG levels in diabetics in moderate to advanced CKD can be similarly interpreted. The reversed ratio in HD patients suggests relative failure of protective mechanisms in diabetics in this setting, resulting in an increased calcification potential.

Blockade of advanced glycation end products receptor signalling prevents the glycated albumin induced overexpression of collagen IV
A.I. Serban[1], M.C. Munteanu[2], M. Costache[2], A. Dinischiotu[2];
[1]Biochemistry and Molecular Biology, University of Agricultural Science and Veterinary Medicine, [2]Biochemistry and Molecular Biology, University of Bucharest, Faculty of Biology, Romania.

Background and aims: The expansion of mesangial cells, accumulation of extracellular matrix protein, thickening of glomerular and tubular basement membranes, tubulointerstitial fibrosis and glomerulosclerosis occur in the diabetic kidney and AGEs play an important role in these pathological changes. AGEs may promote pro-fibrotic cellular responses by interacting with their receptor-RAGE or by other pathways in which TGF-β has a pivotal role. Our aim was to investigate the relationship between AGE, RAGE and TGF-β in collagen IV expression in cultured human embryonic kidney cells (HEK293) exposed to glycated BSA (AGE-BSA).
Materials and methods: Cultured cells were treated for 24 hours with AGE-BSA or BSA (control) at concentrations between 50-200 μg/ml in the presence or absence of 20 ng/ml anti-RAGE antibodies. The level of RAGE, TGF-β1 and procollagen α1 (IV) mRNAs was analyzed by quantitative real-time PCR whereas their protein expression was assessed by Western immunoblot (RAGE and collagen IV) and ELISA (TGF-β1).
Results: The mRNA relative expression ratio (R) increased for all target genes proportionately with AGE-BSA concentration. At 100 μg/ml AGE-BSA, R increased to 1.41+/- 0.12, 1.23+/- 0.05, 2.68+/- 0.17 for RAGE, TGF-β1 and procollagen α1 (IV), whereas at 200 μg/ml AGE-BSA was the highest increase of R to 1.83+/- 0.2, 3.4+/- 0.09 respectively 4+/-0.12. The protein levels of RAGE, TGF-β1 and collagen IV were in good correlation with the mRNA expression. The co-treatment with anti-RAGE antibody and 100μg/ml AGE-BSA versus anti-RAGE antibody and 100μg/ml BSA decreased R to 0.65+/-0.09 for procollagen α1 (IV), whereas the mRNA expression of TGF-β1 remained unchanged. In addition, R increased to 2.1 +/-0.2 for RAGE. The relative proteins levels decreased to 0.42 for collagen IV and to 0.62+/-0.12 for protein TGF-β1 but the RAGE one was 1.6 suggesting that the presence of ligand stimulated RAGE expression.
Conclusion: This study demonstrated that the collagen IV synthesis is modulated by the axis AGE-RAGE-TGF-β1, and was increased in an AGE-BSA concentration dependent manner. It appeared that the presence of AGE-BSA induced the increase of RAGE expression when the number of receptors was diminished by anti-RAGE antibodies treatment. These events were probably involved in the development of fibrosis processes related to diabetic nephropathy.

Aldosterone blockade ameliorates nephropathy by increasing glucose-6-phosphate dehydrogenase activity and reducing oxidative stress in diabetic hypertensive rats
M.V. Shanmuganathan, B.S. Pessoa, E.B. Peixoto, J.M. Lopes de Faria, J.B. Lopes de Faria;
Renal Pathophysiology Laboratory, University of Campinas (UNICAMP), Sao Paulo, Brazil.

Background and aims: Oxidative stress is at the center of pathogenesis of diabetic nephropathy. Hyperglycemia decreases glucose-6-phosphate dehydrogenase (G6PD) activity that makes cells very sensitive to oxidant damage via reducing NADPH formation. Spironolactone, a mineralocorticoid receptor blocker, diminishes hyperglycemia induced reduction in G6PD activity. In the present study we investigated whether spironolactone improves nephropathy by increasing G6PD activity and reducing oxidative stress in hypertensive diabetic rats.
Methods: Spontaneously hypertensive rats were rendered diabetic by intravenous injection of streptozotocin (50 mg/kg), control rats received citrate buffer. The diabetic animals were randomized to receive or not receive spironolactone (50mg/kg/day) for 8 weeks. Albumin excretion rate was determined in 24 h urine by ELISA. Renal expression of fibronectin and p47phx were assessed by Western blot. G6PD activity was determined in renal cortex by estimation of the rate of production of NADPH. The antioxidant system,

glutathione, was estimated as the ratio of reduced form of glutathione (GSH) / oxidized form of glutathione (GSSG) by an enzymatic method. Comparisons between groups were done with one-way analysis of variance (ANOVA) followed by Bonferroni test. Nonparametric data were analyzed by Kruskal-Wallis test (for multiple groups) and Mann-Whitney U test (for 2 groups). A value of $p<0.05$ was considered significant.
Results: Plasma glucose levels were higher ($p<0.0001$) in diabetic rats and it was not modified by spironolactone. Likewise, systolic blood pressure was unaltered by diabetes or by treatment. Albuminuria and renal expression of fibronectin were higher ($p=0.01$ and $p=0.03$, respectively) in the diabetic group compared to control, and these parameters were reduced with the mineralocorticoid receptor blockade. G6PD activity and the GSH / GSSG ratio were reduced ($p=0.008$ and $p=0.02$, respectively) in diabetic rats and the treatment restored to control levels. Urinary levels of 8-hydroxi-deoxiguanosine (8-OHdG), a marker of oxidative stress-induced DNA damage was determined by ELISA and found to be higher ($p=0.02$) in diabetic rats when compared to controls, and the treatment reduced to control levels. The production of superoxide induced by NADPH oxidase (lucigenin) and p47phox, an isoform of NADPH oxidase, was higher ($p=0.009$ and $p=0.004$, respectively) in diabetic rats when compared to controls and was significantly reduced in treated rats.
Conclusion: These results suggest that spironolactone ameliorates nephropathy in the diabetic hypertensive rats by restoring G6PD activity and diminishes oxidative stress without affecting blood pressure.

Uncoupled endothelial nitric oxide synthase is ameliorated by green tea (camellia sinensis) in diabetic SHR rats
A.M. Faria, M.V. Shanmuganathan, J.M. Lopes de Faria, J.B. Lopes de Faria;
Faculty of Medical Sciences, State University of Campinas, Brazil.

Background and aims: It has been shown that in hypertensive diabetic rats green tea (GT, *Camellia sinensis*) ameliorates nephropathy by reducing oxidative stress. In experimental diabetic nephropathy, NADPH oxidase and eNOS uncoupling are major sources of local superoxide production. Uncoupled eNOS is a consequence of a reduction in tetrahydrobiopterin (BH4), an essential cofactor required for the synthesis of nitric oxide (NO). Therefore, uncoupled eNOS leads to a reduction of NO bioavailability which is associated with progression of diabetic nephropathy. The aim of the present study was to investigate if green tea can ameliorates uncoupled eNOS in hypertensive diabetic rats.
Materials and methods: Twelve-week-old spontaneously hypertensive rats (SHR) were rendered diabetic by intravenous injection of streptozotocin (50 mg/Kg), control rats received citrate buffer. Diabetic SHR rats were randomized to receive no treatment or treatment with daily, freshly prepared, GT (13.3 g/L). After 12 weeks of treatment, endothelial and oxidative stress markers were assessed in renal cortex. The levels of BH4 were measured in urine and renal cortex samples using UPLC (Ultra Performance Liquid Chromatography). The results were compared by analysis of variance (ANOVA) followed by Fisher's protected least-significant difference test.
Results: The systolic blood pressure did not differ between groups of the study. However, body weight was less ($p < 0.0001$) and glycemia was greater in diabetic SHR rats (treated or not with GT) than in nondiabetic rats ($p < 0.0001$). Oxidative stress, assessed by NADPH oxidase induced superoxide production, was higher in diabetic rats than in controls ($p=0.01$). The formation of peroxynitrite, a result of the binding of NO to superoxide also increased in diabetic rats ($p = 0.01$). GT attenuated renal ROS production by decreasing the production of superoxide ($p=0.01$) and nitrotyrosine (NT) ($p=0.04$). In diabetic animals, the caveolin-1 (CAV-1), a negative regulator of eNOS expression, was significantly increased ($p=0.02$) and reinstated by GT treatment ($p=0.01$). Immuno-precipitation studies revealed a significant decrease in the CAV1-eNOS binding in diabetic rats ($p=0.03$). Total biopterin, BH4 and oxidation rate of BH4 were measured in urine and renal cortex to assess the bioavailability of NO and the eNOS uncoupling. In diabetic rats, we observed a significant decrease ($p<0.0001$) in the levels of total biopterin and BH4 and moderate change ($p=0.004$) in oxidation rate of BH4 in both urine and renal tissue. GT reversed oxidation of BH4 ($p=0.05$), but not modified BH4 production.
Conclusion: In summary**,** green tea GT ameliorated superoxide production and improved the eNOS uncoupling by reversing CAV-1 expression and oxidation of BH4.

Cilnidipine additively inhibits the progression of renal impairment in diabetic rats when used in combination with an angiotensin II receptor blocker (ARB)
K. Matsuura[1], Y. Mori[1], S. Aritomi[2], K. Niinuma[2], T. Konda[2], Y. Itoh[1], J. Yokoyama[1], N. Tajima[1];
[1]Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, [2]R & D Division, Exploratory Research Laboratories, Ajinomoto Pharmaceuticals Co., Ltd, Kawasaki, Japan.

Background and aims: Cilnidipine represents the only calcium channel blocker (CCB) currently available that antagonizes not only the L-type but the N-type calcium channels and is known to provide renal protection by decreasing the activity of the sympathetic nervous system and the renin-angiotensin system (RAS). However, very few studies evaluated cilnidipine for renal protection in diabetic nephropathy. In this study, therefore, we investigated the effect of the L/N-type CCB cilnidipine, as compared to the L-type CCB amlodipine, on diabetic nephropathy in spontaneously type 2 diabetic rats (OLETF rats), when used in combination with an angiotensin II receptor blocker (ARB).
Materials and methods: Seventeen-week-old OLETF rats were randomly assigned to receive cilnidipine (Cil), amlodipine (Aml), valsartan (Val), Cil + Val, Aml + Val, or vehicle (5% HMC; control) for 22 weeks via a gastric tube, with a total of 16 rats assigned to each group.
Results: Antihypertensive potency was found to be nearly equal between the monotherapy groups and between the combination therapy groups compared. Blood pressure lowering with either treatment did not significantly affect the glycemic variables evaluated. However, the increases in urinary albumin excretion (UAE) seen with progression of diabetic renal impairment were significantly suppressed in the rats given Cil or Val, with their additive suppression seen in those given Cil + Val. Furthermore, the norepinephrine (NE) level in the renal tissue as an indicator of sympathetic nervous system activity was shown to be significantly decreased in those given Cil + Val. With regard to the plasma RAS-related variables, Val tended to increase plasma renin activity (PRA) and angiotensin II (Ang II) activity through a feedback mechanism resulting from inhibition of the Ang II type 1 receptor (AT1-R). Additionally, while significant increases in PRA and Ang II were seen in those given Aml + Val, as may be the case with antihypertensive therapy, no increases in PRA and Ang II were seen in those given Cil + Val, a comparably potent antihypertensive regimen.
Conclusion: Study results revealed that cilnidipine produces additive antihypertensive and UAE-lowering effects when combined with an ARB even in type 2 diabetic rats. Furthermore, combination therapy with cilnidipine and valsartan has been shown to significantly reduce NE secretion, suggesting that cilnidipine suppresses the increases in PRA and Ang II associated with antihypertensive therapy by inhibiting the activity of the sympathetic nervous system through its N-type calcium channel antagonism. Thus it is suggested that cilnidipine may inhibit the progression of nephropathy in type 2 diabetes by inhibiting the activity of the sympathetic nervous system as an N-type CCB.

Telmisartan, an angiotensin II type 1 receptor blocker, prevents renal injury via inhibition of the Notch pathway in Ins2 Akita diabetic mice
M. Koshizaka, M. Takemoto, K. Yokote;
Clinical Cell Biology and Medicine, Chiba University, Japan.

Background and aims: There are an increasing number of patients with end-stage renal disease caused by diabetic nephropathy (DN). It has been recently reported that the Notch pathway is involved in the pathogenesis of DN and the activated Notch pathway induces apoptosis to the podocytes. We investigated the activation of the Notch pathway in Ins2 Akita (Akita mouse), a murine model of DN, and the effects of telmisartan, an angiotensin II type1 receptor blocker, on the Notch pathway and whether telmisartan could prevent podocytes apoptosis.
Materials and methods: Akita mice and control mice received telmisartan (5 mg/kg/day) or no treatment, respectively, for 15 weeks. Body weight, blood pressure, and urinary albumin excretion were measured. The effects of telmisartan on the Notch pathway were studied by RT-PCR and immunohistochemisty both *in vivo* and *in vitro* using cultured murine podocytes. And podocytes were treated with angiotensin II (AII) in the presence or absence

of telmisartan. After that, apoptosis was defined as the presence of nuclear condensation on Hoechst staining. Alternatively, the Annexin V/propidium iodide assay was carried out and analyzed by flow cytometry.
Results: Compared to the control mice, the levels of urinary albumin excretion, serum BUN, and creatinine were higher in the Akita mice (10.9 mg/day, 22.2 ± 3.8 mg/dl, and 0.07 ± 0.01 mg/dl vs. 50 mg/day, 64.7 ± 12.3 mg/dl, and 0.19 mg/dl, respectively; $P < 0.05$). Telmisartan treatment significantly decreased those in Akita mice (33 mg/day, 30.2 ± 6.7 mg/dl, and 0.09 ± 0.01 mg/dl, respectively; $P < 0.05$). The intracellular domain of Notch1 (ICN1) is proteolytically cleaved from the cell membrane in the course of the Notch activation. The expression of ICN1 and its ligand, Jagged1, were increased in the glomeruli of Akita mice, especially in the podocytes. Administration of telmisartan significantly ameliorated the expression of ICN1 and Jagged1. Telmisartan inhibited the AII-induced increased expression of transforming growth factor β (TGF-β) and vascular endothelial growth factor A (VEGF-A) which could directly activate the Notch pathway in cultured murine podocytes. TGF-β and VEGF-A increased the expression of the Notch target gene, Hairy /Enhancer of split-related 1 (*Hes1*), and telmisartan suppressed those expression. Flow cytometer studies showed that apoptotic cells were increased in the podocytes treated with AII (12.56 ± 1.9% vs. 7.09 ± 1.4% in the control group, $P < 0.01$) and telmisartan treatment significantly decreased the AII-induced apoptotic cells (8.51 ± 2.0% vs. 12.56 ± 1.9% in the AII group, $P < 0.01$). We also examined the apoptosis by the use of Hoechst 33342 staining. Nuclear condensations were observed in the podocytes in the presence of AII and those changes were significantly decreased when the podocytes were treated with telmisartan.
Conclusion: The Notch signaling pathway was activated in podocytes in Akita mice. Telmisartan suppressed the Notch pathway both *in vivo* and *in vitro*. And telmisartan suppressed the podocyte apoptosis induced by AII. The AII induced podocytes apoptosis via the activating Notch pathway and telmisartan inhibited that through the inhibition of the Notch pathway. Our results indicate that telmisartan prevents DN through the inhibition of the Notch pathway.

1225

Tubular damage in type 2 diabetic nephropathy: the effect of ultrahigh doses of irbesartan

S.E. Nielsen[1], K. Rossing[1], B.R. Jensen[1], H.-H. Parving[2,3], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]Department of Medical Endocrinology, Rigshospitalet, Copenhagen, [3]Aarhus University, Denmark.

Background and aims: Blockade of the renin-angiotensin-aldosteron system (RAAS) is renoprotective in diabetic kidney disease, and has been shown to affect both the glomerulus and tubules. We aimed to investigate the effect of the angiotensin II receptor blocker irbesartan on the tubular markers: urinary(u) neutrophil gelatinase associated protein(NGAL), kidney injury molecule 1(KIM1) and liver-fatty acid-binding protein(LFABP).
Materials and methods: Substudy of a double-masked, randomized, cross-over study including 52 hypertensive type 2 diabetic patients with microalbuminuria. After 2 months washout of all antihypertensive medication except bendroflumethiazid, patients were treated with irbesartan 300, 600 and 900 mg o.d. for 2 months. Endpoints: 3x24hour(h) urine albumin excretion(UAER), 24h blood pressure, glomerular filtration rate (GFR, ^{51}CrEDTA) and tubular markers measured at baseline and after each treatment period with ELISA (Roche).
Results: Fifty-two patients completed the study(41 male). Age (mean(SD)): 58(10) years and diabetes duration 13(8) years. At baseline, ambulatory blood pressure was 140(11)/ 77(7) mmHg, GFR 101 (24)ml/min/1.73m^2 and UAER [geometric mean (95%CI)] 133 (103-172)mg/24h. As previously reported UAER was significantly more reduced on 900 mg Irbesartan compared to lower doses. Levels of the tubular markers at baseline were: [geometric mean (95%CI)]: u-KIM1 3.6 (2.9-4.5)(pg/ml)/creatinine, u-NGAL 139 (104-187)(pg/ml)/creatinine, and u-LFABP 42 (29-59)(pg/ml)/creatinine. U-NGAL at baseline were tightly related to GFR (R=0.46, p<0.01), whereas u-LFABP and u-KIM 1 were not (p>0.5). U-albumin at baseline was not associated with any of the tubulus markers: NGAL (R=0.08, p=0.6), u-LFABP (R=0.07, p=0.7) or u-KIM1(R=0.03, p=0.8). With increasing doses of irbesartan (300, 600, 900 mg) u-KIM1 was reduced to (geometric mean) 3.1, 3.3 and 3.1 (p=0.07 between 900 mg vs. baseline and no difference between doses). U-NGAL did not change significantly (135, 135 and 138) (p>0.7 compared to baseline, N.S. between doses). U-LFABP did not change during treatment (57.9, 61.8 and 45.1).
Conclusion: Ultrahigh doses of irbesartan treatment reduced levels of the tubular markers u-KIM1 and u-NGAL in type 2 diabetic patients, although not significant. This is in contrast to previous studies in diabetic nephropathy where an ACE inhibitor has reduced markers of tubular damage. More studies with longer follow up are needed to determine the role of tubular markers in monitoring treatment effect and prediction of prognosis in diabetic nephropathy.

1226

Influence of rosiglitazone on proteinuria and renal haemodynamic in type 2 diabetic patients with overt diabetic nephropathy

F. Pistrosch[1,2], K. Herbrig[1], J. Passauer[1], B. Kindel[3], P. Gross[1], S.R. Bornstein[3];
[1]Nephrology, Dept of Medicine, University Hospital, [2]Centre for Clinical Studies, Technical University, [3]Endocrinology, Dept of Medicine, University Hospital, Dresden, Germany.

Background and aims: Proteinuria reflects overt glomerular damage and its degree determines the progression of diabetic nephropathy (DN). Recent studies demonstrated an improvement of renal endothelial function and a reduction of microalbuminuria by activation of the PPAR gamma receptor in early stages of DN. The aim of the present study was to investigate the influence of the thiazolidindione rosiglitazone (RSG) on proteinuria and renal endothelial function in overt DN.
Materials and methods: We conducted a double blind placebo (PLC) controlled study in 28 patients (24 men, 4 women, mean age 66.1 ± 9.1 yr) with type 2 diabetes, proteinuria > 300 mg/24 hr (despite the use of ACE-inhibitor or angiotensin receptor blocker) and an estimated glomerular filtration rate (GFR) < 60ml/min. Patients were randomly assigned to RSG (4mg b.i.d.) or matching PLC in addition to their previous antidiabetic medication. GFR and renal plasma flow were measured by inulin- and p-aminohippurate-clearance before and after the blockade of nitric oxide (NO) by intravenous administration of N-monomethyl-L-arginine-acetate (L-NMMA).
Results: During 12 months of follow up there was a significant reduction of proteinuria in the RSG group (2.46 ± 2.3; 1.25 ± 1.2 and 1.6 ± 1.4 g/24 hr at baseline; 6 and 12 months respectively; P<0.05) but not in the PLC group (1.56 ± 1.4; 1.63 ± 1.9 and 1.66 ± 1.9 mg/24 hr at baseline; 6 and 12 months respectively). HbA1c within each treatment group did not change significantly (7.3 ± 0.8 vs. 7.3 ± 1.1 % for PLC and 6.9 ± 0.8 vs. 6.5 ± 0.7 % for RSG; baseline vs. 12 months follow up; respectively). Decline of GFR during the study was equal between RSG and PLC (4 ml/min). RSG increased intrarenal NO bioavailability as indirectly shown by the infusion of L-NMMA. RSG treatment was associated with more adverse events: most common were increase of body weight and development of peripheral edema, however congestive heart failure did not occur.
Conclusion: RSG reduced proteinuria in overt DN and improved intrarenal NO bioavailability. RSG treatment did not deteriorate GFR but was associated with fluid retention.

1227

Comparison of nifedipine retard and ACE inhibitor with respect to the influence on renal function in hypertensive patients with type 2 diabetes - J-MIND study / reanalysis using eGFR

G. Yoshino[1], T. Kazumi[2], R. Kikkawa[3];
[1]Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Toho University School of Medicine, Tokyo, [2]Department of Food Science and Nutrition, School of Human Environment, Mukogawa Women's University, Nishinomiya, [3]Health and Welfare Policy Division, Shiga Prefecture, Ohtsu, Japan.

Background and aims: It has been described in JSH2009 that strict blood pressure control as well as glycemic control is important for hypertensive patients with diabetes, and the target blood pressure is aimed at lower than 130/80 mmHg. However, although the first-line drug for this disease is ARB or ACE inhibitor, administration of Ca antagonist with strong antihypertensive effect is needed for attaining the target blood pressure. We have conducted the J-MIND (The Japan Multicenter Investigation of Antihypertensive treatment for Nephropathy in Diabetes) study, a 2-year randomized comparative study of nifedipine retard (N group) and enalapril (E group) with respect to the effect on the onset/progression of nephropathy in hypertensive patients with type 2 diabetes, and reported that the renal protection effect indexed by urinary albumin excretion rate was similar in both groups. Since a formula for estimated glomerular filtration rate (e-GFR) suitable for Japanese was newly established currently, the influence on renal function was comparatively studied using eGFR between the 2 groups.

Patients and methods: The subjects of this study were 424 hypertensive patients with type 2 diabetes at the age of lower than 75 years with 140 mmHg or higher baseline systolic blood pressure (SBP), or 90 mmHg or higher diastolic blood pressure (DBP), in whom eGFR could be calculated. Patients were classified based on CKD Stage (eGFR<60, 60-89, >90) (stage 1: 121 cases, stage 2: 199 cases, stage 3: 104 cases), and the 2-year transition of renal function was compared between the 2 groups. The transitions of blood pressure and eGFR were evaluated using Student's t-test.
Results: The mean dose in the N group and the E group was 28.2 ± 11.5 mg/day and 6.4 ± 2.5 mg/day, respectively, and no significant difference was observed in the status of glycemic control between the 2 groups. In both groups, SBP and DBP showed significant decrease during the period after 6 to 24 months ($p<0.001$), whereas SBP showed significant decrease after 6 and 12 months in the N group compared with the E group ($p<0.001$, <0.05) and DBP showed significant decrease after 6 and 24 months in the N group compared with the E group ($p<0.001$, <0.05). No significant fluctuation was observed in eGFR throughout the period of 2 years in all cases in both groups, showing the maintenance of renal function. When the 2 groups were compared with respect to changes of eGFR by CKD stage, continuous increase in eGFR was observed in the stage 3 patients (eGFR<60) during the period after 6-24 months in the N group ($p<0.05$). Whereas in the stage 1 and 2 patients (60<eGFR<90), no significant increase in eGFR was observed in both groups.
Conclusion: The results of this study suggested that long-term administration of nifedipine retard has renal protection effect similar to or higher than ACE inhibitor in terms of eGFR, and the effect is notable in patients with lower eGFR.

Prevention of microalbuminuria: predictors for a good response to olmesartan treatment (ROADMAP Trial)

G. Viberti[1], E. Ritz[2], L. Ruilope[3], H. Haller[4], for the ROADMAP Steering Committee;
[1]King's College London School of Medicine, London, United Kingdom, [2]University of Heidelberg, Germany, [3]Leiden university Medical Centre, Netherlands, [4]Medical School Hannover, Germany.

Background and aims: Microalbuminuria (MAU) is an early sign of diabetic nephropathy and increased cardiovascular risk. We investigated whether early treatment with an angiotensin receptor blocker (ARB) in diabetic subjects with normal albumin excretion delays the occurrence of MAU and analysed subgroups that would benefit most from treatment.
Materials and methods: We studied 4,447 subjects with type 2 diabetes and at least one additional cardiovascular risk factor in a randomized, double-blind, multicentre, controlled, and event-driven (MAU) trial. They received either 40 mg olmesartan medoxomil (OM) or placebo (Pb) od. For a median duration of 3.2 years. In both groups, additional antihypertensive treatment (except ACE inhibitors or ARBs) was used to reach the target BP of <130/80 mmHg.
Results: During the double blind period, 178 (8.2%) subjects in the OM group and 210 (9.8 %) subjects in the Pb group developed MAU (HR: 0.770; 95.1% CI: 0.630 to 0.941, p: 0.01). To identify factors influencing the response to OM treatment, explorative post-hoc subgroup analysis using the corresponding median at baseline as a cut-off were performed. This analysis revealed that the treatment effect on time to onset of MAU was better in subjects with a SBP >135 mmHg than with SBP values ≤135 mmHg. A baseline HbA1c ≤7.3% and an eGFR ≤83.79 were predictors for a better response to OM treatment. Furthermore, less than 5% of patients with a baseline UACR ≤4 mg/g developed MAU during the study and the rate was similar between the OM and Pb treated patients. In contrast, 13.9% in the OM group and 18.1% in the placebo group with a baseline UACR >4 mg/g developed MAU (time-to-onset: HR: 0.75, 95% CI: 0.60 to 0.96, p-value= 0.02).
Conclusion: In subjects with type 2 diabetes olmesartan showed a significant 23% risk reduction regarding time to onset of microalbuminuria. Patients with a baseline SBP>135 mmHg, an eGFR ≤83.79, or an UACR >4mg/g benefit most from olmesartan treatment. ClinicalTrials.gov ID no.: NCT00185159.

PS 122 Cardiovascular risk and assessment

1229

Benchmarking cardiovascular event rates in type 2 diabetes controlled clinical studies by modification of the UKPDS risk engine

M. Stewart[1], J. Ye[2], F. Yang[1];
[1]GlaxoSmithKline, King of Prussia, [2]GlaxoSmithKline, Research Triangle Park, USA.

Background and aims: With the release of the new FDA recommendations for evaluating CV risk in new antidiabetic therapies, models predicting population CV event rates have become critical to the design of clinical trials. In order to successfully demonstrate no increased CV risk, these trials must be adequately powered, with consideration of the appropriate patient demographics and CV history. Although recent outcomes studies have provided evidence of CV safety for specific agents or agent combinations, baseline patient characteristics and underlying CV risk in these populations are not uniform across studies. While the UKPDS risk engine provides a well-accepted basis for estimating CV risk in patients with newly diagnosed disease, the aim of this analysis was to develop a CV risk prediction benchmark for the general diabetes population.
Materials and methods: Summary CV risk data from ADOPT, ADVANCE, VADT, ACCORD, RECORD, PROactive and BARI-2D studies was directly applied to the UKPDS model, and an evaluation/comparison on the prediction of annualized Major Acute Coronary Events (MACE) event rates (myocardial infarction, stroke and CV death) was performed.
Results: The direct prediction of the annualized CV event rate based on the original UKPDS model was inconsistently over-estimated for all studies except for PROactive [predicted event rate vs. observed event rate with mean (SD) = 1.5 (0.26)]. However, when previous CV history is added to the UKPDS model and evaluated across these studies, a more consistent (yet higher) prediction across all studies was generated [Table, observed vs. predicted rate mean (SD) = 2.1 (0.12)].
Conclusion: The modified UKPDS risk model provides a consistent benchmark for CV event rates in clinical study populations more closely resembling a general population of patients with type 2 diabetes.

	ACCORD	ADVANCE	VADT	RECORD	PROactive	ADOPT	BARI-2D
Original UKPDS Model							
Observed annualized MACE event rate (overall)	2.2	2.1	4.2	1.5	3.6	0.8	4.7
Predicted annualized MACE event rate	3.7	3.8	5.4	2.2	3.3	1.6	5.4
Predicted event rate /observed event rate	1.7	1.8	1.3	1.5	0.9	2.0	1.2
Modified UKPDS Model							
Predicted annualized MACE event rate	5.0	5.0	8.8	2.5	6.6	1.6	10.8
Predicted event rate /observed event rate	2.3	2.4	2.1	1.8	1.8	2.0	2.3

The role of coronary risk assessment in planning and assessing treatment of type 2 diabetes

T.M. Phillips[1], P.J. Phillips[2], J. Wang[2];
[1]Southern Adelaide Health Service, [2]North West Adelaide Health Service, Australia.

Background and aims: Coronary heart disease (CHD) is the major complication in type 2 diabetes. An individual's risk for coronary events is important for planning future treatment. Furthermore information on the changes in coronary risk over time is useful in assessing the effectiveness of interventions. Finally coronary risk assessment can assist explaining potential treatment benefits for patients and thereby increasing treatment adherence. This study assessed initial and at follow-up (two years later) coronary risk in a cohort of type 2 diabetes patients managed in Australian general practice and reviewed in a tertiary teaching hospital. We also reported the risk factors associated with significant reductions in coronary risk.
Materials and methods: Over 1402 type 2 diabetes patients who had both the initial and the follow-up assessment were included in the study. The data on the following variables have been analysed: age, BMI, HBA1c, blood pressure, cholesterol level, self-reported smoking and exercise data. The CHD risk is calculated using the UKPDS risk engine.
Results: At the follow-up assessment after an average of two years, apart from age, the other contributing variables to CHD risk - HbA1c, blood pressure, cholesterol and % of the smoking patients have all improved. The 5 year CHD risk has significantly increased due to the effects of increasing age (Table 1). After removing age effect (i.e. assuming same age as on the initial assessment) the mean 5 year CHD risk at the follow-up assessment is 13.1%, significantly lower than that at the initial assessment. The improvement of the lipids over the period is the single biggest beneficial factor for the CHD risk. The improvement of these risk factors is mostly due to increased use of medication for cholesterol and blood pressure control, oral anti-hyperglycaemic medication and insulin for controlling blood glucose level. Patients with lower initial HbA1c had maintained their CHD risk after adjusting for age while those who had HbA1c >8% had their CHD risk significantly reduced after age adjusted although the risk remained higher than those with lower HbA1c.
Conclusion: The results showed that all major targeted risk factors for diabetes management, including HbA1c, blood pressure, cholesterol levels and smoking, have improved in this cohort of type 2 diabetes patients. The increased CHD risk is solely a function of age increase and the age adjusted 5 year CHD risk is actually reduced. This reflected an overall adequate management of this cohort of diabetes patients while the biggest beneficial effect is from the improvement of lipid profile.

Table 1. The change of patient characteristic and CHD risk (mean and 95% CI or %)

	Initial assessment	Follow up assessment	P
Age	60.2 (11.98)	62.2 (11.96)	<0.01
BMI	31.4 (6.75)	31.3 (6.76)	<0.05
HbA1c	7.45 (1.55)	7.42 (1.53)	<0.05
Systolic BP	139.2 (21.21)	137.9 (20.56)	<0.05
Diastolic BP	79.0 (11.91)	77.3 (11.63)	<0.01

Residual cardiovascular risk due to persistent dyslipidaemia in statin-treated patients with diabetes mellitus in Ireland: results of the Dyslipidaemia International Study

J.O. Ryan[1], J. Crowley[2], J. Feely[3], B. McAdam[4], E. Shanahan[5], C. Vaughan[6];
[1]Department of Endocrinology & Metabolism, Cork University Hospital, [2]Cardiology Department, University College Hospital Galway, [3]Department of Pharmacology & Therapeutics, St. James' Hospital, Dublin, [4]Department of Cardiology, Beaumont Hospital, Dublin, [5]General Practice, Farranfore, [6]Department of Cardiology, Mercy University Hospital, Cork, Ireland.

Background and aims: Dyslipidaemia is an established independent risk factor for cardiovascular disease (CVD) in patients with diabetes mellitus (DM). This study examined the number of patients with DM on treatment with a statin that had normal and abnormal lipid levels according to ESC/EASD guidelines.
Materials and methods: The Dyslipidaemia International Study (DYSIS) was a multi-national cross-sectional study. In Ireland, patients were recruited consecutively by 58 general practitioners and 4 cardiologists. Entry requirements included age >45 years, statin-treatment for >3 months, consent to physical examination, and at least one lipid profile in the past 6-12 months.
Results: In Ireland 980 eligible patients were studied. 181 patients (20.1%) had DM. Despite patients with DM having significantly lower LDL-c levels than patients without DM, triglyceride and HDL-c levels were less likely to be normal in patients with DM (Table 1). The Odds Ratio (O.R.) for a parental history of DM was 3.32 in the DM group versus the non-DM group. Significant differences in systolic blood pressure levels and anti-hypertensive agents used existed between the groups.
Conclusions: The results of DYSIS in Ireland show that triglyceride and HDL-c levels remain abnormal in statin-treated patients with DM. This is in keeping with the international findings in this study. These patients remain at increased CVD risk and supplementary treatment may be indicated.

Table 1. Biochemical and historical results for DYSIS in Ireland

	Patients with DM N=181 (20.1%)	**Patients without DM** N=719 (79.9%)
LDL-c (mmol/L) [Median and Quartiles]	1.9 (1.4 - 2.3)	2.3 (1.8 - 3.0)*
LDL-c <2.59mmol/L	82.4% (145/176)	62.1% (428/689)*
Triglycerides <1.7mmol/L	53.3% (96/180)	68.3% (477/698)**
HDL-c >1.03 Male/ 1.29 Female (mmol/L)	44.9%	67.1%*
Systolic B.P. (mmHg) [Mean and S.D.]	136.9 (+/- 17.9)	133.9 (+/- 17.4) ***
ACE Inhibitor treatment	59.7%	31.3%* O.R.=3.25
HbA1c (available in 150/181 - 82.9%)	6.9 (6.2 - 8.0)	-
Anti-diabetic therapy	77.3% (140/181)	-
Parental history DM	23.2% (42/181)	8.3%* (60/719) O.R.=3.32

Factors predicting cardiovascular events in statin-treated diabetic and non-diabetic coronary patients: a prospective cohort study

H. Drexel[1,2], S. Greber[1], T. Gansch[1], P. Rein[1,2], A. Vonbank[1,2], C.H. Saely[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Prinicpality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Statins are a cornerstone in the management of high risk patients. However, residual risk in patients with established coronary artery disease (CAD) remains high. We aimed at identifying which lipid factors drive vascular risk in statin treated patients with CAD.
Materials and methods: We recorded vascular events over a mean period of 7.2 years in 491 consecutive statin-treated patients with angiographically proven stable CAD, covering 3518 patient-years.
Results: In the total population, low HDL cholesterol (standardized adjusted HR 0.80 [0.67-0.94]; p=0.009), low apolipoprotein A1 (0.84 [0.72-0.98];

p=0.022), a small LDL particle diameter (0.84 [0.72-0.98]; p=0.023), and high triglycerides (1.18 [1.04-1.35]; p=0.013) predicted vascular events, but not total cholesterol, LDL cholesterol, or apolipoprotein B. Factor analysis in the lipid profiles of our patients revealed an HDL-related factor and an LDL-related factor. Concordant with the results for individual lipid parameters, the HDL-related factor (0.76 [0.65-0.90]; p = 0.001) but not the LDL-related factor (p=0.644) predicted vascular events. Patients with type 2 diabetes (T2DM; n=116) were at a higher vascular risk than non-diabetic subjects (52.6% vs. 36.8%; p = 0.002), and like in the total population the HDL-related factor (0.63 [0.49-0.81]; p<0.001) but not the LDL-related factor (p=0.976) predicted vascular risk in diabetic patients.
Conclusion: The pattern of low HDL cholesterol, low apolipoprotein A1, small LDL particles, and high triglycerides drives vascular risk in statin-treated coronary patients, particularly in those with T2DM.

1233

Cardiovascular disease risk communication for patients with type 2 diabetes: The @RISK Study
L.M.C. Welschen[1], S.D.M. Bot[1], T. van der Weijden[2], D.R.M. Timmermans[1], J.M. Dekker[1], G. Nijpels[1];
[1]EMGO Institute for Health and Care Research, Amsterdam, [2]CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands.

Patients with type 2 diabetes (T2DM) underestimate their risk to develop severe complications, and they do not understand the risk communication of caregivers. According to Leventhal's Self-regulation Theory, patients are not willing to change their lifestyle if they are not informed why this is important. People have correct or incorrect perceptions concerning their disease which determine how they manage their risks to develop severe complications. Providing understandable information on the disease by means of risk communication may change illness perceptions. The aim is to investigate the effects of an intervention focussed on the communication of the absolute 10-year risk to develop CVD on risk perception and illness perceptions in patients with T2DM.
Materials and methods: A randomised controlled trial was performed with newly referred T2DM patients to the Diabetes Care System West-Friesland, a managed care system in the Netherlands. The intervention group (n=131) received CVD risk communication, consisting of an explanation on the causes and consequences of CVD, and possibilities for prevention on top of standard managed care of the DCS. The 10 year risk of developing CVD was explained in natural frequencies and visualised by a population diagram. Controls (n=130) received standard managed care. Outcome measures were appropriateness of risk perception and illness perceptions assessed at baseline, at 2 weeks (immediately after the intervention or control visit), and 12 weeks. Risk perception was measured by asking 'How would you rate your risk of developing CVD in the next 10 years?' The absolute difference between risk perception and the actual CVD risk on the UKPDS risk engine was calculated. The Brief Illness Perception Questionnaire was used to assess illness perceptions. An overall score was calculated by summarizing scores on the 8 items, measured on a 10-point Likert scale. A higher score indicates a more threatening view of the illness. Differences in changes between time points were analysed by t-tests in the intervention and control group.
Results: Mean age was 58.4 ± 10.3 years, the median of diabetes duration was 0.36 (IQR 0.1 - 1.4) years, HbA1c was 6.7 ± 1.3% and 57% were men. In the intervention group, the difference between the actual CVD risk and the risk perception improved significantly between baseline and 2 weeks (see Table 1). This effect remained at 12 weeks. In the control group, no changes were found. No effects were found on illness perceptions.
Conclusion: This innovative risk communication method improved patients' risk perception and this effect remained at the long term. The hypothesis that patients might be better able to manage their disease was not supported, as their illness perceptions showed no changes. Table. Differences in risk perception and illness perceptions in the intervention and control groups.

	Baseline	2 weeks	12 weeks	p (baseline - 2 weeks)	p (baseline - 12 weeks)
Risk perception (difference between risk perception and CVD risk)					
Intervention	9.7 (4.7 - 18.5)	4.6 (1.9 - 11.5)	5.8 (1.8 - 12.1)	0.00 *	0.00 *
Control	8.9 (4.9 - 13.5)	8.9 (5.0 - 14.7)	8.0 (3.6 - 16.3)	0.79	0.22
Illness perceptions					
Intervention	31.7 (12.0)	31.0 (11.4)	30.5 (11.5)	0.54	0.85
Control	31.9 (11.2)	32.0 (12.5)	32.3 (12.4)	0.75	0.55

Data are means (± SD) or median (interquartile range). * P < 0.05

Characteristics, complications and management of a large multiethnic cohort of younger adults with type 2 diabetes
K. Benhalima[1], S.H. Song[2], E.G. Wilmot[3], K. Khunti[4], L.J. Gray[4], I. Lawrence[1], M.J. Davies[3];
[1]Diabetes Research, University Hospital of Leicester, [2]Diabetes Centre, Northern General Hospital, Sheffield, [3]Cardiovascular Sciences, University of Leicester, [4]Health Sciences, University of Leicester, United Kingdom.

Background and aims: An increasing number of young people are diagnosed with type 2 diabetes (T2DM), leading to a high lifetime risk for developing diabetes-related complications. Whether this cohort receives appropriate risk factor management in relation to older T2DM subjects remains uncertain. Our aim is to describe the characteristics and management of a multiethnic cohort of people with T2DM <40 years (<40 cohort) and to compare with T2DM subjects aged ≥ 40 years (≥ 40 cohort).
Petients and methods: Retrospective analysis of data extracted from the last clinic visit of 648 adults (< 40 cohort) attending 2 specialist diabetes centres (A and B) in the UK and a ≥ 40 cohort of 3582 T2DM subjects coming from the specialist centre A. In the < 40 cohort, differences between the first (≤22) vs. fifth quintile (≥33) of age of diagnosis were analysed.
Results: Characteristics of the <40 cohort: 57.9% female, 54.5% Caucasian, 45.5% Black or Minority Ethnic origin (BME, 91.9% from South Asian origin). Median age at diagnosis was 28 years (24-31). Data were extracted after a median diabetes duration of 4.0 years (1.9-7.0). The median BMI was 33.0 kg/m^2 (28.3-38.7), higher in Caucasians (35.0 vs. 30.9 in BME, p<0.0001) and women (34.0 vs. 31.9 in men, p=0.003). Median HbA1c was 8.2% (6.8-9.9) with an HbA1c > 7% in 70%. Cardiovascular risk factors were frequent: 71.8% total cholesterol > 4mmol/l, 54.9% triglycerides > 1.7mmol/l, 45% hypertension. Microvascular complications were also prevalent: 19.8% retinopathy, 14.6% abnormal foot exam, 24.0% microalbuminuria (only available for centre A). Oral antidiabetic drugs were used in 71.6%, insulin alone in 18.6% and both in 24.7%. Insulin was more often used in Caucasians (49.4% vs. 36.2% in BME, p=0.001). 27.7% received antihypertensives, 31.5% a statin and 13.9% aspirin. Women were less likely to be treated for hypertension (22.7% vs. 34.8%, p<0.0001) and dyslipidaemia (22.1% vs. 45.1%, p<0.0001) than men. The first quintile of age of diagnosis had more often retinopathy (22.1% vs. 16.9%, p=0.021) and was treated less aggressively compared with the fifth quintile. Fewer were on insulin (45.6% vs. 46.4%, p=0.039), many were managed with diet only (9.6% vs. 6.2%, p=0.005) and they were less likely to be treated for hypertension (23.2% vs. 32.3%, p=0.583) and dyslipidaemia (30.4% vs. 39.2%, p=0.495). Data were generally comparable between the 2 centres, except for a higher proportion of BME (50.6% vs. 36.1%, p<0.0001) and women (61.3% vs. 51.5%, p=0.009) and lower median HbA1c (8.1% vs. 8.7%, p=0.012) in centre A compared to centre B. Compared to the ≥ 40 cohort, patients in the < 40 cohort were more often female (57.9 vs. 46.1, p<0.0001) and of BME origin (45.5 vs. 30.2 , p<0.0001), had a higher median BMI (33.0 vs. 30.4, P<0.0001) and a higher median HbA1c (8.2 vs. 7.5, p<0.0001).
Conclusion: The <40 cohort represents a more extreme phenotype compared to the ≥ 40 cohort with a high prevalence of inadequately treated risk factors. In particular, patients from the first quintile of age of diagnosis were less aggressively treated. There is a need for tailored strategies to manage this high-risk group.

1235

LDL-cholesterol is not the best blood lipid predictor of CHD risk in type 2 diabetes
B. Eliasson[1], S. Gudbjörnsdottir[1], K. Eeg-Olofsson[1], A.-M. Svensson[2], B. Zethelius[3], J. Cederholm[3];
[1]University of Gothenburg, [2]Center of Registers Vastra Gotaland, Gothenburg, [3]Uppsala University, Sweden.

Background and aims: Although frequently used in clinical practice, the validity of LDL-cholesterol (LDL) as a risk factor for coronary heart disease (CHD) is uncertain. We assessed the roles of different measures of blood lipids in an observational study of type 2 diabetes from the Swedish National Diabetes Register (NDR).
Material and methods: 23,001 patients aged 30-75 years, 16% with previous CVD, 43% with lipid-lowering drugs, were followed from 2003 to 2007, with 1709 fatal/nonfatal CHD events. LDL was calculated with Friedewald's equation.

Results: Adjusted hazard ratios (HR) at Cox regression for fatal/nonfatal CHD per 1 SD of each lipid measure were 1.21 (1.15-1.26) with non-HDL/HDL, 1.19 (1.13-1.24) with LDL/HDL, 1.18 (1.13-12.4) with non-HDL, and 1.14 (1.09-1.19) with LDL; all p<0.001 when adjusted for age, sex, diabetes duration, HbA1c, type of hypoglycaemic treatment, systolic blood pressure, antihypertensive drug use, smoking, BMI, and microalbuminuria (>20 µg/min). Goodness-of-fit with global likelihood ratio X^2 values were 771, 762, 757, 739, respectively. Figure 1 shows splines for adjusted 5-year CHD rates as a cubic function of lipids in a Cox model. CHD rates increased progressively with higher non-HDL/HDL ratio as well as non-HDL. When 7889 patients with a combination of non-HDL/HDL >2.9, non-HDL >3.6, and LDL >2.8 mmol/l was used as reference (median values chosen as limits), fully adjusted HR for CHD risk was 0.61 (0.53-0.70) with non-HDL/HDL <2.3 mmol/l (recently often used target; n=6116), HR was 0.67 (0.60-0.76) with non-HDL <3.3 mmol/l (recent target, suggested useful if higher triglycerides; n=7623), while HR was higher 0.74 (0.66-0.83) with LDL <2.5 mmol/l (recent target in guidelines; n=7166). HR with LDL <1.9 mmol/l was 0.65 (0.54-0.80) (suggested target in high-risk patients; n=1889). All HR were p<0.001.
Conclusion: Non-HDL/HDL and non-HDL, which both are reliably measured in the non-fasting state, were more strongly associated with risk of CHD than LDL. Risk reductions for CHD were larger with targets presented here for the non-HDL/HDL ratio and non-HDL, than for LDL. Splines of CHD rate by non-HDL/HDL and non-HDL values underline the "the lower the better" concept for these lipids and CHD risk in type 2 diabetes.

Silent myocardial ischaemia and prediabetes in combination are associated with adverse prognosis in healthy subjects

T. Intzilakis[1,2], A. Sajadieh[1,2], S.B. Haugaard[3,2];
[1]Dept. of Cardiology, University Hospital of Copenhagen, Bispebjerg, [2]Dept. of Internal Medicine, University Hospital of Copenhagen, Amager, [3]Clinical Research Centre, University Hospital of Copenhagen, Hvidovre, Denmark.

Background and aims: Silent myocardial ischemia (SMI) is prognostic for deaths and myocardial infarction. Prediabetes increases risk of diabetes and cardiovascular disease. It was hypothesized, therefore, that prediabetes deteriorates prognosis in persons with SMI.
Materials and methods: Five-hundred-and-ninety-six non-diabetic subjects from the community of age 55 to 75 years and free of any known cardiovascular disease and cancer were examined by ambulant 48h continuous electrocardiogram monitoring. SMI was defined as at least 1 mm depression of the ST interval on the electrocardiogram of at least 1 min duration. Prediabetes was defined as fasting plasma glucose ≥ 5.6 but < 7.0 mmol/L. During a median follow-up of 6.3 years, 77 subjects met the predefined combined endpoint of acute myocardial infarction and/or death.
Results: Two-hundred-and-twenty-nine subjects had prediabetes (38%), which was not associated with SMI (P=0.69). Subjects with prediabetes and SMI (5% of subjects) more often met the combined endpoint (36%) than subjects with prediabetes and non-SMI (15%), subjects with normal fasting glucose (NFG) and SMI (12%), and subjects with NFG and non-SMI (10%), respectively, (P<0.001). Both in a univariate analysis and in a Cox multivariate analysis, the latter of which included the four study groups of interest, and in addition, gender, age, smoking habits, blood pressure and total cholesterol, respectively, only subjects with combined prediabetes and SMI exhibited an increased risk for meeting the predefined endpoint (hazard ratio, HR: 4.0 (2.0-8.1), P<0,001 and HR: 2.5, CI95% 1.2-5.2, P=0.016, respectively; subjects with combined NFG and non-SMI as reference). Including also high sensitive C-reactive protein and NT pro-brain natriuretic peptide in the Cox multivariate model, subjects with prediabetes and SMI exhibited more than a 3-fold increased risk of meeting endpoint compared with reference subjects (HR: 3.2, CI95% 1.5-6.7, P<0.005).
Conclusion: Combined silent myocardial ischemia and prediabetes suggest increased risk of myocardial infarction and/or death among apparently healthy subjects living in the community, thus, this clinical entity calls for screening and treatment.

Fold risk of meeting endpoint of acute myocardial infarction and/or death

	Univariate	Multivariate (a)	Multivariate (b)
NFG and non-SMI (reference group)	1	1	1
Prediabetes (IFG) and SMI	**3.98 (1.95–8.13)*****	**2.50 (1.20–5.20)***	**3.15 (1.49–6.65)****
Prediabetes (IFG) and non-SMI	1.56 (0.94–2.57)	1.42 (0.85–2.36)	1.58 (0.95–2.63)
NFG and SMI	1.32 (0.51–3.40)	1.10 (0.42–2.85)	1.15 (0.44–3.01)

Cox proportional hazard models of combined normal fasting plasma glucose (NFG, </= 5.5 mmol/L)) or impaired fasting glucose (IFG, range: 5.6–6.9 mmol/L) and silent myocardial ischemia (SMI) or non-SMI in relation to the endpoint acute myocardial infarction and/or death.
Hazards ratios (95% confidence intervals); * P<0.02; ** P<0.005; *** P<0.001
(a) Adjusted for smoking, total cholesterol, systolic blood pressure, gender and age.
(b) Additional adjustment for NT-proBNP and high-sensitive CRP, including adjustments made in (a).

Incident myocardial infarction is five-fold higher in subjects at high risk for type 2 diabetes

M.P. McKenna[1], M.W. Rowe[1], J.A. Kolberg[1], O. Pedersen[2], K. Borch-Johnsen[3], T. Jørgensen[4];
[1]Research, Tethys Bioscience, Emeryville, USA, [2]Faculty of Health Science, University of Copenhagen, Denmark, [3]Steno Diabetes Center, Copenhagen, Denmark, [4]Research Centre for Prevention and Health, Glostrup University Hospital, Denmark.

Background and aims: A simple and accurate test comprised of circulating biomarkers (Diabetes Risk Score, DRS) provides a quantitative estimate of the 5-year risk of developing type 2 diabetes mellitus (T2DM). It is established that T2DM is a major risk factor for cardiovascular disease, and that a significant portion of that risk occurs in the prediabetic state. A model using the circulating biomarkers composing the DRS was applied to the Inter99 study to assess the 5-year risk of cardiovascular events (CVE) in groups of subjects at low, moderate and high risk for T2DM.
Materials and methods: Serum samples collected at baseline from 5452 subjects free of diabetes were tested. 2924 (53.6%), 1975 (36.2%) and 553 (10.1%) subjects were classified as low, moderate and high risk for T2DM, with 5 yr T2DM conversion rates of 0.5%, 3.1% and 15.2%, respectively. Relative risk (RR) estimates for overall CVEs and for each of the 4 classes of CVEs (myocardial infarction (MI), re-vascularization (RV), angina (ANG), and stroke (STR)) were calculated as ratios of moderate:low and high:low. P values and confidence intervals were calculated by bootstrap estimation.
Results: The results are summarized in the table below. Relative risks for overall CVEs and all classes of CVEs were significant with the exception of STR.
Conclusion: Several studies have demonstrated that risk of MI is 3-fold higher in diabetics compared to non-diabetics. The data shown here demonstrate similar levels of cardiovascular risk stratification among non-diabetics using the DRS, suggesting that cardiovascular risk factors for patients with a high DRS should be managed carefully.

Relative Risks for Overall Cardiovascular Events by Diabetes Risk Score

	CVE (n=108)	MI (n=42)	RV (n=42)	ANG (n=27)	STR (n=41)
Low DRS	1	1	1	1	1
Moderate DRS	2.7 (p<0.001)	2.6 (p=0.013)	4.1 (p<0.001)	6.5 (p<0.001)	1.8 (p<0.11)
High DRS	3.6 (p<0.001)	4.8 (p=0.003)	6.0 (p=0.004)	6.7 (p=0.03)	2.6 (p=0.09)

1238

Assessing the influence of modelling subsequent cardiovascular events into a type 2 diabetes cost-effectiveness model

P.H. McEwan[1], M. Evans[2], K. Bergenheim[3];
[1]Cardiff Research Consortium Ltd, United Kingdom, [2]University Hospital Wales, Cardiff, United Kingdom, [3]AstraZeneca, Mölndal, Sweden.

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with increased risk of cardiovascular morbidity and mortality. Assessing the cost-effectiveness of risk factor modification is commonly based on the analysis of avoiding primary events. The aim of this study was to calibrate published equations to allow the prediction of primary and subsequent events and to assess the economic implications of this within a cost-effectiveness model.
Materials and methods: Routine hospital data from across the UK were analysed between 2000 and 2005 to identify patients with T2DM with first, second and third myocardial infarction (MI) or stroke admissions. The ratio of events (primary + subsequent) to primary event was used to calibrate the cardiovascular risk equations using a published diabetes prevalence-based model. The impact of the calibrated equations was then assessed using a published cost-effectiveness model assessing two treatment strategies: 1st line metformin (a) and (b); 2nd line sulphonylurea add-on (a) versus DPP-4 inhibitor add-on (b); 3rd line thiazolidinedione add-on (a) versus DPP-4 inhibitor add-on (b). The model was run using a UKPDS demographic and risk factor profile with a payer perspective for 40 years with costs and benefits discounted at 3.5%.
Results: Between 2000 and 2005, 1,124,846 T2DM patients were identified, of whom 55,868 and 65,436 experienced a primary MI and stroke, respectively. There were 2,159 (3.86%) and 185 (0.003%) second and third MI admissions, respectively, and 5,808 (8.88%) and 755 (0.012%) second and third stroke admissions, respectively. Incorporating subsequent events into the model had little impact on the cost per quality-adjusted-life-years (QALYs), which ranged from £3,105 to £3,129 with and without subsequent events allowed, respectively. The impact on cost per life-year gained (LYG) was more noticeable; £257,902 with primary events only, and £90,055 with primary and subsequent events.
Conclusion: The inclusion of subsequent cardiovascular events into diabetes models provides greater face validity; however, this has little impact on cost-effectiveness. This study supports the conclusion that the economic assessment of therapies that modify cardiovascular risk factors but do not incorporate subsequent MI and stroke events are not significantly biased - due to the relatively small number of subsequent events. Importantly, this does not imply that treatment in clinical practice should be stopped after first event. Where concerns are raised regarding the suitability and generalisability of risk equations in general, and the UKPDS equations in particular, research should focus on deriving and/or validating primary event risk equations to ensure that the assumption of generalisability is indeed robust. For a general cohort of T2DM patients this would appear to be more pressing than the accurate prediction of subsequent events.

PS 123 Biomarkers and cardiovascular disease

1239

Effects of six years intensified multifactorial treatment versus usual care on levels of hs-CRP and adiponectin in patients with screen-detected type 2 diabetes. The ADDITION Netherlands study

J. Berends, M. van den Donk, K.J. Gorter, G.E.H. Rutten;
Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands.

Background and aims: Biomarkers as high-sensitivity C-reactive protein (hs-CRP) and adiponectin are associated with cardiovascular disease. Hs-CRP may be a mediator of atherosclerosis. Elevated levels of hs-CRP and decreased levels of adiponectin are independent markers of cardiovascular disease. It is unknown to what extent these biomarkers are influenced by the intensity of a multifactorial therapy aimed at reduction of cardiovascular disease in type 2 diabetes. We compared the effects of six years intensified multifactorial therapy or usual care on levels of hs-CRP and adiponectin in 498 screen-detected type 2 diabetes patients and the association with cardiovascular morbidity and mortality.
Materials and methods: This study is embedded in the Dutch part of the Anglo-Danish-Dutch ADDITION study, a cluster-randomised clinical trial that studies the effectiveness of intensified multifactorial treatment compared to usual care on cardiovascular morbidity and mortality in screen-detected type 2 diabetes patients. Baseline serum levels of hs-CRP and adiponectin were measured at time of diagnosis of type 2 diabetes by screening (2002-2004). Serum hs-CRP was determined by chemiluminescent enzyme immunoassay. Adiponectin was assessed by immunoassay technique. Final measurements were performed in the second half of 2009. In the stored serum hs-CRP and adiponectin will be determined. We will analyse the difference in change in serum hs-CRP and adiponectin levels between both treatment groups with multilevel modelling, to be able to adjust for clustering at the level of the general practice.
Results: Baseline characteristics in both treatment groups (usual care vs. intensive treatment) are comparable, except for the levels of adiponectin (Table). Hs-CRP was 6.9 mg/dl (SD 8.6) in the usual care group vs. 7.3 (SD 9.9) in the intensified treatment group; adiponectin 6759 ng/ml x100 (SD 3845) in the usual care group vs. 5868 (SD 3172) in the intensified treatment group (p=0.006). A total of 330 (66%) patients from 79 general practices participated in the final measurement. Their data are currently analysed and will be presented at the EASD meeting.
Conclusion: This more than 5 years follow-up of multifactorial treatment in screen-detected type 2 diabetes patients will demonstrate whether intensified therapy leads to a significant change in hs-CRP and adiponectin levels and whether such a change is associated with cardiovascular mortality and morbidity.

Baseline characteristics of the ADDITION Netherlands study

Variables	**Usual care group** (n=243)	**Intensive treatment group** (n=255)
Age (years)	59.9 ± 5.1	60.1 ± 5.4
Gender (% male)	56.0	51.8
BMI (kg/m^2)	30.4 ± 4.6	31.2 ± 5.1
Systolic blood pressure (mmHg)	163 ± 23	166 ± 23
Diastolic blood pressure (mmHg)	89 ± 10	90 ± 11
Fasting blood glucose (mmol/l)	8.1 ± 2.8	7.8 ± 2.3
HbA1c (%)	7.4 ± 1.7	7.3 ± 1.6
Cholesterol (mmol/l)	5.6 ± 1.1	5.6 ± 1.1
Hs-CRP (mg/l)	6.9 ± 8.6	7.3 ± 9.9
Adiponectin (ng/ml x100)	6759 ± 3845	5868 ± 3172

The ENPP1 K121Q polymorphism predicts accelerated cardiovascular events in obese patients with type 2 diabetes

S. Bacci[1], C. Powers[2], A. Pacilli[1], A. Facciorusso[3], T.H. Hauser[4], S.A. De Cosmo[1], Y.-Y. Zhang[5], E.V. Gervino[6], G. Di Stolfo[3], D. Mangiacotti[7], R. Xu[5], M. Copetti[8], S. Prudente[9], A. Doria[5], V. Trischitta[10,11];
[1]Endocrinology Unit, IRCCS, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]Joslin Diabetes Center, Harvard Medical School, Boston, USA, [3]Cardiology Unit, IRCCS, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [4]Cardiovascular Division, Beth Israel Deaconess Medical Center, Boston, USA, [5]Joslin Diabetes Center, Harvard Medical School, Boston, USA, [6]Cardiovascular Division, Beth Israel Deaconess, Boston, USA, [7]Laboratory of Diabetology, IRCCS, San Giovanni Rotondo, Italy, [8]Biostatistics Unit, IRCCS, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [9]Genetics laboratory, IRCCS, Casa Sollievo della Sofferenza-Mendel, Rome, Italy, [10]Diabetes Laboratory, IRCCS, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [11]Sapienza Univesity, Rome, Italy.

Type 2 diabetes is characterized by insulin resistance and accelerated atherosclerosis. The *ENPP1* K121Q polymorphism has been associated with both of these traits, especially among obese individuals. We investigated the role of the *ENPP1* K121Q polymorphism - separately in non-obese and obese individuals (body mass index < or ≥ 30 kg/m^2) - as a predictor of major cardiovascular events in a prospective study of 330 type 2 diabetic patients with coronary artery disease at baseline. Study subjects were followed for 37.1±19.4 months, during which 43 major cardiovascular events occurred (32 cardiovascular deaths, 3 non-fatal myocardial infarctions, and 8 non-fatal strokes). Carriers of the Q121 variant (either KQ or QQ individuals) had an increased risk of incident events among obese subjects (n=159, HR=3.56, 95% CI=1.21-10.46, p=0.02), but not among non-obese individuals (n=171, HR=0.90, 95% CI=0.39-2.06, p=0.81). A similar pattern of association was observed in a cross-sectional study of 339 type 2 diabetic patients (169 subjects from Italy and 170 from the US) who had survived a myocardial infarction. In this analysis, patients who had had the myocardial infarction at a younger age (≤ 50 years, n=112) were compared to those who had had the myocardial infarction at an older age (n=237). Since no genotype-by-sample interaction was observed, data from Italy and the US were pooled and analyzed together. As seen in the prospective study, the Q121 variant was associated with a significantly increase in the risk of early myocardial infarction among obese subjects (n=188; OR=2.51, 95% CI=1.29-4.88, p=0.007), but not among non-obese individuals (n=151; OR, 95% CI=1.11, 0.51-2.42 p=0.878). In conclusion, among obese individuals with type 2 diabetes, the *ENPP1* Q121 variant contributes in accelerating cardiovascular events.

1241

Leptin and glucose intolerance predict independently a first-ever myocardial infarction with a sex difference - data from a large prospective population-based study in northern Sweden

M. Eriksson[1], G. Hallmans[1], J.-H. Jansson[1], T. Olsson[1], P. Vennberg[1], L. Weinehall[2], S. Söderberg[1];
[1]Dept of Public Health and Clinical Medicine, Medicine, [2]Dept of Public Health and Clinical Medicine, Epidemiology, Umeå, Sweden.

Background and aims: The adipocyte-derived hormone leptin mediates several processes associated with glucose hemostasis and atherosclerosis, and data suggests that high leptin may predict diabetes and cardiovascular disease (CVD). As circulating levels and signalling differ between males and females we explored whether leptin also predict first-ever myocardial infarction or sudden death with a sex difference, independent of glucose intolerance.
Materials and methods: This is a prospective nested case-referent study. Subjects (n=564, 40% females) with a first-ever acute myocardial infarction (MI) (fatal and non-fatal, and classified according to WHO) that had participated in population-based studies (the Väserbotten project, the MONICA survey, and the mammary screening cohort) prior to the event (3.9 years) were identified in the Northern Sweden MI registry. Matched (age, sex, survey date and location) referents (n=1082, 40% women) free of CVD were recruited from the same database. Glucose intolerance was categorised into impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and diabetes mellitus (DM) based on an OGTT and data on treatment at baseline. The impact of leptin and glucose intolerance on future MI was explored in conditional logistic regression analyses and odds ratios (OR) with 95 % confidence intervals were calculated.
Results: At baseline, both males and females with MI had higher leptin levels (5.0 ng/mL vs. 4.1 ng/mL, p<0.001 and 15.4 ng/mL vs. 14.0 ng/mL, p=0.03) compared to referents. High leptin levels predicted MI in males but not in females, independently of glucose intolerance, 1.9 (1.1-3.0) and 1.0 (0.5-2.0), respectively. After further stratification, leptin predicted ST elevation MI but not non-ST elevation MI in males, 2.9 (1.4-6.4) and 1.4 (0.6-3.6), respectively. After adjustments including leptin, DM and IGT associated with MI, ORs 2.3 (1.3-4.1) and 2.4 (1.3-4.0), respectively. After stratification for sex, DM associated with MI in men and IGT with MI in women, ORs 2.5 (1.4-4.5) and 4.1 (1.4-12.1), respectively.
Conclusion: High leptin and glucose intolerance predict first-ever fatal and non-fatal MI, notably with a clear gender difference.

Assessment of matrix metalloproteinase-9 as a non-traditional cardiovascular risk marker in prediabetes and newly diagnosed type 2 diabetes

N. Chakarova[1], T. Tankova[1], G. Kirilov[1], L. Dakovska[1], A. Tsakova[2];
[1]Clinical Center of Endocrinology, [2]Department of Clinical Laboratory and Immunology, Medical University, Sofia, Bulgaria.

Background and aims: Matrix metalloproteinase-9 (MMP-9) is a proteolytic enzyme which main substrate is basement membrane collagen and it has been lately recognized as a non-traditional marker of cardiovascular risk. There is growing evidence that MMP-9 plays a key role in extracellular matrix degradation and remodeling and is involved in all stages of the atherosclerotic process. The aim of the present study was to assess MMP-9 levels in prediabetic states - impaired fasting glucose (IFG) and impaired glucose tolerance (IGT), and in newly diagnosed type 2 diabetes (NDD) as well as to evaluate the relationship between MMP-9 and glycaemic control (blood glucose, HbA1c), anthropometric parameters (body mass index, visceral fat area) and common cardiovascular risk factors (hsCRP, serum lipids).
Materials and methods: 249 subjects, distributed into four age-, sex- and BMI-matched groups, were enrolled in the study - 63 subjects with normal glucose tolerance (NGT) (32 males and 31 females, mean age 49.6±14.2 years, mean BMI 30.0±5.0 kg/m^2), 62 subjects with IFG (32 males and 30 females, mean age 49.4±11.1 years, mean BMI 30.6±5.8 kg/m^2), 62 subjects with IGT (31 males and 31 females, mean age 49.0±13.8 years, mean BMI 30.6±6.7 kg/m^2) and 62 subjects with newly diagnosed type 2 diabetes (32 males and 30 females, mean age 48.7±10.6 years, mean BMI 30.4±5.3 kg/m^2). Glucose tolerance was studied during oral glucose tolerance test with evaluation of venous plasma glucose at 0 min and 120 min by a hexokinase method (Roche Diagnostics). hsCRP, lipid profile, MMP-9 and HbA_{1c} were estimated at fasting state. hsCRP was measured turbidimetrically (Roche Diagnostics). Lipid profile (total cholesterol, HDL-cholesterol, triglycerides) was assessed by an enzymatic colorimetric method (Roche Diagnostics). LDL-cholesterol was calculated using Friedewald's formula. MMP-9 was assessed immunoenzymatically (ELISA, CalBiochem) and HbA_{1c} - immunoturbidimetrically (Roche Diagnostics). BMI and visceral fat area were measured with body composition analyzer using eight-point multi-frequency bioelectric impedance analysis (InBody 720, BIOSPACE). Statistical analysis was performed with SPSS 16.
Results: No significant difference in MMP-9 level was found between the groups with NGT and NDD as well as between NGT group and either of the prediabetic groups. No correlation was established between MMP-9 level and glycaemic control parameters. Significant negative correlation was established between MMP-9 and HDL-cholesterol level (r=-0.24, p<0.05). We have found significant correlation between MMP-9 and hsCRP (r=0.482, p=0.04) as well as between MMP-9 and BMI (r=0.391, p<0.01) and visceral fat area (r=0.346, p<0.02).
Conclusion: In early stages of impaired glucose homeostasis - prediabetes and newly diagnosed type 2 diabetes, serum MMP-9 levels do not differ significantly from those in subjects with normal glucose tolerance. In prediabetes and NDD serum MMP-9 correlates mainly with anthropometric (BMI, visceral fat area) and inflammatory (hsCRP) markers and shows weak correlation with parameters of metabolic control (HDL-cholesterol). Probably MMP-9 activity in these states is related to inflammatory changes rather than to metabolic ones.

High osteoprotegerin serum levels in newly diagnosed type 2 diabetic males with or without known coronary artery disease

M. Boyadzhieva[1], K. Hristozov[1], S. Georgiev[2], R. Yordanov[2], T. Chervenkov[3], N. Usheva[4];
[1]Endocrinology, University Hospital, [2]Clinic of Interventional Cardiology, University Hospital, [3]Laboratory of Clinical Immunology, University Hospital, [4]Social Medicine and Health Care, Medical University, Varna, Bulgaria.

Background and aims: Osteoprotegerin (OPG) is an inhibitor of osteoclastogenesis, but is produced from vasculature too. Recently increased circulating OPG levels were found in diabetics and in patients with coronary artery disease (CAD). Elevated serum OPG appears to be a powerful predictor for cardiovascular mortality. Up to date there are insufficient data for OPG concentrations in newly diagnosed type 2 diabetic patients. The aim of our study was to determine serum OPG in males with newly diagnosed T2DM associated or not with known concomitant CAD and to investigate the relationship between OPG and metabolic components.
Materials and methods: Serum OPG levels were measured in 45 newly diagnosed type 2 diabetic males and 20 age- and BMI-matched normoglycemic male subjects. The newly diagnosed diabetics consisted of 28 diabetics without history of CAD and 17 diabetic patients who underwent percutaneous coronary interventions (PCI) for CAD. Mean intima-media thickness (IMT) of common carotid arteries in diabetics without known CAD was measured by B-mode ultrasonography. All newly diagnosed glucose abnormalities were detected during 2 screening programs among risk groups. Glucose tolerance was defined by performing a standard OGTT. OPG was measured by ELISA (BioMedica).
Results: OPG was significantly higher in newly diagnosed type 2 diabetics compared to controls (4.4 ± 0.2 vs 3.3 ± 0.4 pmol/l; p=0.02) but there was no significant difference between diabetic males with performed PCI or those without known CAD - 4.2± 0.3 vs 4.6 ± 0.3 pmol/l, p=0.41 respectively. In total group of subjects, there was positive correlation of OPG levels with fasting plasma glucose (r=0.37, p=0.008), 120 min post-OGTT glucose (r=0.42, p=0.004) and HbA1c (r=0.50, p=0.0002). Interestingly, in newly diabetic males OPG correlated only with HbA1c (Pr 0.40, p=0.009). Moreover in diabetics without known CAD, OPG correlated significantly with carotid IMT (Pr 0.48, p=0.03) and age (p=0.04). There was no association with fasting insulin, homeostasis model assessment of insulin resistance (HOMA-IR), systolic and diastolic blood pressure, BMI or waist circumference. From lipid parameters OPG showed positive correlation only with HDL-cholesterol (r=0.34, p=0.02).
Conclusion: We found higher serum OPG levels in newly diagnosed type 2 diabetic males independently of presence of known CAD. OPG showed association with glucose parameters, early markers of atherosclerosis and probably they may be involved in the regulation of OPG. We suggest that OPG rises early in the evolution of diabetic disorders but further investigations are needed.

Serum YKL-40 levels predict the development of vascular complications in patients with type 2 diabetes

Y. Suzuki[1], Y. Sakuma[2], R. Iwai[2], T. Yamane[1], S. Yoshida[1], N. Hashimoto[3];
[1]Diabetes and Metabolic disease, Asahi General Hospital, Asahi-City, Chiba, [2]Clinical Laboratory, Asahi General Hospital, Asahi-City, Chiba, [3]Diabetes,Endocrine and Metabolic disease, Tokyo Women's Medical University, Yachiyo-City, Chiba, Japan.

Background and aims: Macrophages in atherosclerotic plaques and vascular smooth muscle cells secrete YKL-40, associated with inflammation, endothelial dysfunction and increased tissue remodeling. Progression of nephropathy with increasing levels of albuminuria has been reported to be intimately linked to an increased risk of cardiovascular (CV) disease. The aim of the present study was to examine the changes in serum YKL-40 levels in patients with type 2 diabetes with increasing levels of albuminuria and macroangiopathy.
Materials and methods: A total of 396 patients with type 2 diabetes were enrolled in this study: 212 males/184 females, age 60±13 years, estimated duration of the disease 12±8 years, body mass index (BMI) 26.0±4.6 kg/m^2,HbA1c 7.4±1.4%. Two hundred fifteen patients had normoalbuminuria, and 122 had persistent microalbuminuria, and 59 had overt proteinuria (macroalbuminuria). Ninety patients showed the past history of CV events (macroangiopathy). The control group consisted of 100 healthy individuals with normal glucose tolerance matched for gender and age. Examination included blood and urine samples for CV risk factors, and markers including lipids, high sensitive C-reactive protein (hsCRP), interleukin (IL)-6 and adiponectin in addition to YKL-40.
Results: Serum YKL-40 levels were positively correlated with age (r=0.333, p<0.0001), systolic blood pressure (r=0.144, p<0.005), serum creatinine (r=0.218, p<0.0001), urinary albumin-to-creatinine ratio (r=0.279, p<0.0001) and IL-6 (r=0.243, p<0.0001). However no significant correlation was found between YKL-40 and parameters such as BMI, HbA1c and hsCRP. Serum levels of adiponectin were not related to levels of YKL-40 in patients with normoalbuminuria (r=0.005.p=0.9405) but both parameters interestingly showed significant correlation in patients with microalbuminuria (r=0.266, p<0.005). YKL-40 levels had no gender differences, and were significantly elevated in patients with type 2 diabetes compared with control subjects (135.8±94.7 vs. 80.7±58.3 ng/ml; p<0.0001). YKL-40 levels were evidently increasing with advancing stages of nephropathy (normoalbuminuria 105.2±74.0, microalbuminuria 156.5±98.0 and macroalbuminuria 205.3±107.8 ng/ml; p<0.005 for all comparisons). Patients with the past CV events showed significantly higher YKL-40 levels than other patients (165.4±99.4 vs. 126.3±91.5 ng/ml; p<0.001).
Conclusion: YKL-40 levels are significantly elevated in patients with type 2 diabetes with advancing stages of nephropathy, and also in patients with macroangiopathy. These findings suggest that YKL-40 has the usefulness as a novel marker predicting the progressing vascular complications in patients with type 2 diabetes.

Insulin resistance: a risk marker in coronary population without known diabetes

E. Hernandez[1], J.M. De la Hera[1], I. Lozano[1], J.M. Vegas[2], J.M. Garcia-Ruiz[1], P. Avanzas[1], C. Fernandez-Cimadevilla[1], A. Carro[1], T. Menendez[3], E. Delgado[3];
[1]Cardiology, Hospital Universitario Central de Asturias, Oviedo, [2]Cardiology, Hospital Clínico Universitario, Valladolid, [3]Endocrinology, Hospital Universitario Central de Asturias, Oviedo, Spain.

Background and aims: The impact of clinically established diabetes in the prognosis of the patients with coronary disease is well known. However, contradictory data exist about the prognosis if these patients present unknown diabetes, newly detected diabetes or prediabetes. As the phisiopathologic substrate is the insulin resistance the purpose is to validate its role as prognosis factor in our series.
Materials and methods: We studied a cohort of 472 patients with coronary disease [(who underwent percutaneous coronary intervention (PCI)]. In those 338 patients without known diabetes an analysis including fasting plasma glucose, oral glucose tolerance test, glycated hemoglobin, insulinemia, and renal and lipid profiles was performed 15 days after discharge. The real glycometabolic profile of the population was addressed following the OMS criteria of 1999. The HOMA was calculated with Matthews´formula. Insulin resistance was defined as HOMA>3 (Sekiguchi et al). A composite end-point of major cardiac events (MACE) that included death, non-fatal AMI, new PCI and stroke was registered after a 12-month follow-up. Kaplan-Meier and multivariable analysis were performed to determine the predictors of MACE.
Results: Age: 66.5 (56-74), males 80.1%, active smokers 28.4%, hypertension 49.7%, obesity 35.5%, peripheral or cerebrovascular disease 15.4%. The real distribution of the cohort after the glycometabolic study was: known diabetes 28.8%, newly detected diabetes 16.2%, prediabetes 25.5% and normoglycemic 29.5%. Forty patients were classified as resistance to insulin and 298, non insulin resistance. In the multivariable analysis the predictors of MACE were the presence of known diabetes (30.6%) and insulin resistance (27.5%). The MACE in non insulin resistance, normoglycemics, prediabetes and newly detected diabetes were 11%, 10.7%, 10.7% and 12.9%, respectively. (See Kaplan-Meier curve, DM is known diabetes).
Conclusion: In our cohort of patients with coronary disease who underwent PCI the presence of known diabetes and the insulin resistance were predictors of MACE at 12 months. Prediabetes and newly detected diabetes did not increase the risk of MACE in comparison with the normoglycemics.

Abdominal obesity, hypertension and cardiovascular risk in diabetic patients: Poland compared to North-West Europe Region - insights from IDEA sub-study

M. Wróbel[1], M. Chrostowska[2], A. Szymborska-Kajanek[1], P. Paczwa[3], J.-P. Després[4], K. Narkiewicz[2], K. Strojek[1];
[1]Department of Internal Diseases Diabetology & Nephrology, SIilesian Medical University, Zabrze, Poland, [2]Hypertension Unit, Dept. of Hypertension & Diabetology, Medical University Gdańsk, Poland, [3]Sanofi Aventis, Warszawa, Poland, [4]Quebec Heart and Lung Institute, Université Laval, Canada.

Background and aims: The cluster of anthropometric and metabolic disorders define the risk of cardiovascular disease (CVD). The IDEA (International Day for Evaluation of Abdominal Obesity) study was an international cross sectional study including 168159 primary care patients in 62 countries. The aims of the present report were: (i) to compare the prevalence of abdominal obesity (AO), hypertension (HT) and cardiovascular disease (CVD) in Poland-PL and North-West Europe Region -NW (Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Netherlands, Norway, Sweden, Switzerland) in diabetic (DM) sub-population of IDEA study; (ii) to assess the impact of DM and AO, HT on CVD in Polish population.
Materials and methods: In Poland, 200 randomly selected general practitioners included 5371 consecutive patients, aged 18 to 80 years, 2024 men and 3347 women. Waist circumference (WC), BMI, the presence of DM, HT and CVD (defined as coronary heart disease, stroke, or revascularization) were recorded. AO was diagnosed according to the NCEP criteria (WC >102 cm for male (M) and >88 cm for female (F).
Results: The prevalence of DM in PL vs. NW was 12.7% vs. 12.9% in M and 10.8% vs. 8.8% in F (p<0.001), respectively. The prevalence (%) of abnormalities in risk factors in diabetic sub-population is shown in the table. . In multiple logistic model, age (OR=1.075, 95% C.I. 1.07-1.08, P<0.001), AO (OR=1.41, 95% C.I. 1.15-1.73, P<0.001), male gender (OR= 1.60, 95% C.I. 1.37 - 1.85, P<0.001), DM (OR= 1.70, 95% C.I. 1.4 - 2.06, P<0.001) and HT (OR= 3.15, 95% C.I. 2.7 - 3.68, P<0.001) were independent predictors for CVD in Poland. The impact of AO, HT and DM on CVD were independent of gender (P>0.1 for interaction). DM added to combination of AO and HT increased the aged-adjusted probability of CVD (95% C.I) from 41% to 54% in M (p<0.001) and from 30% to 42% in F (p<0.001), respectively.
Conclusion: The population profile of cardiovascular risk factors in diabetic patients is worse in Poland when compared with North and Western Europe. This difference was more striking for women. These results contribute to increased burden of CVD, and require novel intensive preventive strategies in Poland.

Table

	Male		Female	
	PL n=257)	NW (n=1646)	PL (n=364)	NW (n=1473)
BMI>30 kg/m^2	56**	43	59**	51
AO	65	59	85*	80
HT	76	72	77	73
CVD	62**	41	55**	35
	*p<0.05; ** p<0.001 vs. NW

Gender differences in the progression of atherosclerosis of carotid and coronary arteries using MDCT and carotid ultrasonography

N. Hashimoto[1], T. Haruki[1], H. Matsuura[1], C. Karasawa[1], J. Ogino[1], Y. Suzuki[2];
[1]Diabetes, Endocrine, and Metabolic Diseases, Yachiyo Medical Center, [2]Diabetes, and Metabolic Diseases, Asahi General Hospital, Japan.

Background and aims: Cardiovascular disease (CVD) is a leading causes in death with type 2 diabetes and it is important to prevent onset of CVD. One of the clinical intervention and screening of CVD is multiple detector-row computed tomography (MDCT) to detect the progression of atherosclerosis. Ultrasonic evaluation of early carotid is also a useful tool for the prediction of occurrence of ischemic cerebrovascular events. We are routinely using these examinations for early detection of atherosclerotic evaluation and intervention with medical treatment. Here, we tried to clarify the significance of carotid ultrasonography and MDCT in gender in order to screen the atherosclerotic changes.
Materials and methods: A total of 115 patients (men: 74, women: 41) with type 2 diabetes attending Yachiyo Medical Center,Tokyo Women's University were studied. Mean patients ages were 64.4 years old for men and 66.8 for women. Mean body mass index (BMI) was 24.2±3.4 kg/m^2. Ultrasound examination for carotid intima-media thickness (IMT), max IMT, plaque character, number (plaques score) and echolucency were used. The plague score was calculated by summing the maximum of intima-media complex (plaque thickness) measured in millimeters on the near and far walls at each of four divisions of both sides of the carotid arteries. Quantification of coronary artery calcium was examined according to Agaston scores.
Results: Plaque score in men was 8.03±0.70 and 6.37±0.60 in women and there was no significant difference. Calcium score in coronary arteries in men was 630.4±156.5, and 157.8±34.6 in women and there was a significant difference between them (P<0.05). There was a tendency to increase in a ratio of calcium score and plaque scores in men compared with in women, but there was not significant difference (P=0.06). Not calcium score but plaque score was positively significantly correlated with the duration of diabetes (p<0.05). Calcium scores were positively correlated with numbers of echorich plaques in both men and women (P<0.01) but not with echolucent plaques. Interestingly, significant correlation between calcium score and plaque score was not observed in total subjects (r=0.12, P=0.21) and there was no correlation in men (r=0.07, P=0.52), but there was strong correlation in women (r=0.389, P<0.01).
Conclusion: Carotid ultrasonography is a useful non-invasive screening for atherosclerotic evaluation and prediction for coronary and cerebrovascular events, but there is a significant correlation between plaque score and calcium score in MDCT in women, but not in men. Carotid ultrasonography is predictive for coronary atherosclerosis in women suggesting that the investigation of active coronary atherosclerosis examination is necessary regardless of severity of carotid ultrasonograhy results in men.

1248

Screening strategy for asymptomatic coronary heart disease in Japanese patients with diabetes mellitus

Y. Kawasaki, S. Honjo, Y. Hamamoto, H. Ikeda, Y. Wada, H. Koshiyama; Center for Diabetes and Endocrinology, Kitano Hospital, Osaka, Japan.

Background and aims: Although type 2 diabetes has been indicated to be equivalent risk to myocardial infarction in Finnish study, Japanese subjects with type 2 diabetes has been indicated to be less frequently associated with coronary heart disease (CHD) than Caucasians. In the present study we investigated screening methods of asymptomatic CHD with type 2 diabetes.
Materials and methods: All patients with type 2 diabetes of our outpatient department (OPD) (n=558) were checked with electrocardiography (ECG) at rest, and all of inpatients with type 2 diabetes (IN) (n= 573) were checked with both ECG at rest and Treadmill tolerance test (TTT). Those with previous history of CHD or contraindication for TTT were excluded. The OPD patients with abnormal ECG findings were investigated with TTT and/or thalium 201 cardiac scanning (TCS). Thereafter the subjects (both IN and OUT) with abnormal TTT and/or TCS findings were examined with coronary angiography (CAG) in order to make a final diagnosis of CHD.
Results: Among 558 OPD patients, 134 subjects had abnormal ECG at rest, and 52 of them received TTT and/or TCS. A total of 4 subjects received CAG and all of them were finally indicated to have CHD. Among 573 IN patients, a total of 70 had positive TTT, and 61 patients received TCS. Among 61 patients, a total of 22 (36.1%, ie 3.8 % of total) had positive TCS. There were no significant differences of basal clinical parameters between the TCS-positive group and TCS-negative group, except for female dominance in negative group.Thirty-seven (52.9%) of TTT-positive patients and 10 (45.5%) of TCS-positive patients had one or more of the following; abnormal ECG at rest, history of other macroangiopathy, or more than two cardiovascular risk factors. Among TCS-positive patients, a total of 14 subjects received CAG, and eight of them (ie 57.1%) were finally indicated to have CHD; five cases received percutanous coronary intervention (PCI), two cases received coronary bypass surgery (CABG), and the remaining one case was followed with medication.
Conclusion: These results suggest that a risk factor-guided screening approach for asymptomatic CHD may not be sufficiently adequate, at least, in Japanese patients with type 2 diabetes.

1249

Diabetic retinopathy is a risk factor for cardiovascular disease in Japanese patients with type 2 diabetes. The Otowa Hospital Diabetes Observational Study 2 (OHDOS 2)

K. Inoue[1], T. Shimada[2], H. Koyama[1], M. Shigemoto[1], K. Doi[1]; [1]Department of Endocrinology and Metabolism, [2]Department of General Internal Medicine, Rakuwakai Otowa Hospital, Kyoto, Japan.

Background and aims: Type 2 diabetes is a potent risk factor for cardiovascular disease (CVD). Recently microvascular complications of diabetes are increasingly recognized as independent risk factors for CVD. For example, there is increasing evidence that nephropathy has strongly and independently been associated with the development of CVD. Diabetic retinopathy is also increasingly recognized as an independent CVD risk factor, but there is less evidence than nephropathy. Therefore, the aims of our study were to further explore the relationship of retinopathy with CVD in Japanese patients with type 2 diabetes.
Materials and methods: Overall 568 consecutive outpatients with type 2 diabetes who came to Rakuwakai Otowa Hospital in Kyoto, which is a teaching hospital with 588 beds, in 2003 were studied retrospectively for 6 years or until they experienced a cardiovascular event or died. CVD during follow-up was defined as myocardial infarction, angina, silent myocardial ischemia and stroke. Retinal findings were classified into three categories according to the status of the more impaired eye: no retinopathy, nonproliferative retinopathy, and proliferative retinopathy. Statistical analysis was performed by Cox proportional hazard model to estimate hazard ratios of retinopathy.
Results: The mean age of 568 patients was 63±12 years. Approximately 38% of patients were women (350 men and 218 women). Median duration of diabetes were 10.0±9.7 years, and 21% of patients were taking aspirin. The mean glycated hemoglobin (HbA1c) was 7.8%. One hundred four patients had nonproliferative retinopathy (18.3%) and 69 patients had proliferative retinopathy (12.1%). After 6 years follow-up, 102 patients had incident CVD (18.0%). Figure 1 shows Kaplan-Meier curves for the cumulative incidences of CVD by the grade of retinopathy. After 6 years follow-up, both nonproliferative retinopathy (Cox model hazard ratio [HR], 2.58; 95% confidence interval [CI] 1.58 to 4.20; p<0.001) and proliferative retinopathy (HR 3.59; 95% CI 2.00 to 6.44; p<0.001) had increased CVD risks. These associations were independent of sex, age, duration of diabetes, history of smoking, LDL cholesterol, HDL cholesterol, chronic kidney disease (CKD), hypertension, and history of CVD. In the group of patients with history of CVD, HRs of incident CVD were 2.29 (95% CI 1.07 to 4.89; p=0.032) and 3.26 (95% CI 1.39 to 7.64; p=0.007) in patients with nonproliferative and proliferative retinopathy. In the group of patients without history of CVD, both nonproliferative retinopathy (HR 2.98; 95% CI 1.54 to 5.75; p=0.001) and proliferative retinopathy (HR 4.00; 95% CI 1.67 to 9.61; p=0.002) had strongly increased CVD risks.
Conclusion: This study shows that Japanese type 2 diabetes patients with nonproliferative or proliferative retinopathy had an increased risk for incident CVD.

Targeting intensive glycaemic control versus conventional glycaemic control in type 2 diabetes mellitus - a meta-analysis of 29,000 patients

B. Hemmingsen[1], S.S. Lund[2], C. Gluud[1], A.A. Vaag[2], T.P. Almdal[2], C. Hemmingsen[1], J. Wetterslev[1];
[1]Copenhagen Trial Unit, Centre of Clinical Intervention Research, Rigshospitalet, [2]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Patients with type 2 diabetes mellitus (T2D) have increased mortality primarily due to increased risk of cardiovascular disease (CVD). Epidemiological studies suggested an association between elevated blood glucose and the development of both micro- and macrovascular complications. However, recent randomised clinical trials (RCTs) have questioned the benefit of intensive glucose control. The aim of this systematic review was to assess the effects of targeting intensive versus conventional glycaemic control in patients with T2D.
Materials and methods: RCTs that prespecified different targets of blood glucose control in the intervention arms were identified through searches of The Cochrane Library, MEDLINE, EMBASE, Science Citation Index Expanded, LILACS and CINAHL. We contacted relevant companies, experts and conference proceedings from major diabetes congresses. RCTs in adults with T2D irrespective of language and publication status were included. Two authors independently extracted data. If needed additional information was obtained from authors.
Results: Nineteen RCTs were included, randomising 29,977 patients with T2D (16,085 to intensive control, 13,860 to conventional control). The mean duration of the intervention varied from 3 days to 12.5 years. The relative risk (RR) for the primary outcomes of all-cause mortality (fixed RR 1.00, 95% CI 0.93 to 1.08) or CVD mortality (fixed RR 1.05, 95% CI 0.95 to 1.17) was not significant. Meta-regression for all-cause mortality showed no significant influence of disease duration, HbA1c or fasting blood glucose at baseline. However, the risk of all-cause mortality was negatively correlated to duration of the intervention (P= 0.08). The risk of CVD mortality was not influenced by the variables explored by meta-regression. Intensive glycaemic control significantly reduced the risk of non-fatal myocardial infarction (fixed RR 0.86, 95% CI 0.78 to 0.96; P=0.006) and amputation of lower extremity (fixed RR 0.64, 95% CI 0.44 to 0.95; P=0.03). The RRs of non-fatal stroke, cardial revascularization and peripheral revascularization were not significant. Intensive glycaemic control reduced the risk of all microvascular complications (fixed RR 0.85, 95% CI 0.78 to 0.93; P=0.0003), including nephropathy (fixed RR 0.80, 95% CI 0.70 to 0.91; P=0.0007) and retinal photocoagulation (fixed RR 0.79, 95% CI 0.69 to 0.91; P=0.002). Non-hypoglycaemic serious adverse events were more common when targeting intensive glycaemic control (fixed RR 1.06, 95% CI 1.02 to 1.11; P=0.003). The risk of severe hypoglycaemia was increased when targeting intensive glycaemic control (fixed RR 2.71, 95% CI 2.42 to 3.02; P<0.00001). The cost-effectiveness of intensive glycaemic control was neutral. It was not possible to meta-analyse quality of life.
Conclusion: There is insufficient evidence to determine whether targeting intensive glycaemic control versus conventional glycaemic control reduces all-cause mortality and CVD mortality. Meta-regression showed negative correlation between duration of the intervention and all-cause mortality. Intensive glycaemic control reduces key clinical, including all microvascular outcomes. However, conventional glycaemic control reduces the risk of severe hypoglycaemia and other serious adverse events.

Differences in the short-term medium-term and long-term outcomes between newly diagnosed diabetes patients known diabetic and prediabetic patients after an acute coronary syndrome

A. Koutsovasilis[1], A. Melidonis[1], I. Protopsaltis[1], A. Kamaratos[1], V. Dragoumanos[1], A. Charamis[1], A. Sereti[1], S. Foussas[2];
[1]Diabetes Center, [2]Cardiology Department, Tzaneio General Hospital, Piraeus, Greece.

Background and aims: Diabetes is a major contributor to cardiovascular diseases, as well as an independent predictor for adverse outcomes in patients after an Acute Coronary Syndrome (ACS). The impact of different categories of glucose metabolism on patient outcome after discharge varies according to elapsed time after ACS. The aim of this study is to determine the correlation of these categories with the incidence of short-term and long-term complications after an ACS.
Materials and methods: 520 patients mean aged 66.14±11.94 years that were admitted to the coronary care unit and discharged were included in this longitudinal, prospective, observational, study. The study's end- points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Short-term was defined at 30 days after discharge, medium-term at 6 months, and long-term at 12 months. Non-diabetic patients went through an Oral Glucose Tolerance Test one month after discharge and IGTs were categorized. Adjusted and unadjusted logistic regression analyses were carried out in order to find the correlation between the glycemic status of the patients and the incidence of complications during the first 30 days and one year after their discharge.
Results: Out of the study's 520 patients, diabetes was previously diagnosed (Group A) in 152 (29.2%) patients, newly diagnosed (Group B) in 57 (10.9%) patients, and IGT (Group C) was observed in 110 (21.1%) patients while 201 (38.8%) were patients with normal glucose regulation (Group D). Regarding the patient outcome after the first 30 days following ACS, group B had the worst outcome (HR:2.15, 95%CI: 1.109-4.156, p=0.001), followed by groups A (HR:1.87, 95%CI: 1.228-5.231, p=0.003) and C (HR:1.22, 95%CI: 0.976-2.985, p=0.112) using group D as a reference group after adjustment for age, gender, smoking, waist circumference, HDL, triglycerides, total cholesterol, metabolic syndrome (NCEP-ATP III criteria) and hypertension. According to patients' outcome six months after ACS, group A shows the worst outcome (HR: 2.05, 95%CI:1.211-5.781, p=0.001) followed by group B (HR:1.92, 95%CI:1.149-4.483, p=0.001) and group C(HR:1.23, 95%CI:0.985-3.244, p=0.109) using group D as reference category. There was no difference between group A and B (p=0.244). Concerning patient outcome during the first 12 months after ACS, group A showed the worst outcome (HR:2.66, 95%CI:1.234-5.135,p=0.001) followed by groups B(HR:1.84, 95%CI:1.129-4.328,p=0.022) and C(HR:1.25, 95%CI: 1.115-3.289,p=0.046) using group D as reference group after adjustment to the before mentioned factors.
Conclusion: Newly diagnosed diabetic patients with ACS show a worse short-term outcome compared to known diabetic patients due to the fact that those patients have diabetes that was neither appropriately recognized nor treated before hospitalization. Patients with known diabetes mellitus have a worse long-term outcome after ACS compared with newly diagnosed and IGT patients, while there are no differences between known and newly diagnosed diabetes patients in medium-term outcome.

1252

Ethnic differences in the prevalence of cardiovascular disease and its risk factors in subjects with and without diabetes in Oslo, Norway

A.T. Tran[1], A.K. Jenum[2], H.E. Meyer[3], K.I. Birkeland[2], J. Straand[1];
[1]Section for General Practice and Community Health, Institute of Health and Community, University of Oslo, [2]The Diabetes Research Center, Aker University Hospital, [3]Institute of Health and Community, University of Oslo, Norway.

Background and aims: The population in Oslo is multiethnic due in large part to immigration from Asia and Africa in the last decades. In these ethnic minority groups, we have previously reported a high prevalence of diabetes, diabetes was diagnosed at a younger age and the glycaemic control was poorer compared to Norwegians. The aim of the present study was to assess the prevalence of self-reported diabetes and cardiovascular disease (CVD) and its risk factors related to diabetes status in five minority groups compared with the Norwegians.
Materials and methods: Data from three population-based health surveys conducted in Oslo between 2000 and 2002 were merged. Of 54473 invited individuals 24749 (45.4%) participated. Our study was restricted to participants born in Norway, Turkey, Iran, Sri-Lanka, Pakistan and Vietnam between 1940 and 1971 (N=18417). Data about self-reported diabetes, CVD (coronary heart disease and/or stroke), physical inactivity, body mass index (BMI), blood pressure (BP), glucose and lipids for subjects with and without diabetes were analyzed. We used country of birth as proxy for ethnicity as the minorities in this study are mainly 1. Generation immigrants. Chi-square testes, multiple regression and logistic regression were used.
Results: Of the 17854 study subjects with known diabetes status, 562 reported diabetes. Table 1 gives the age, ethnic composition, disease prevalence and risk factors of the study population. The prevalence of self-reported diabetes varied from 1.9 % (Norwegians) to 13.3% (Pakistanis), p<0.001, and the eth-

nic minority groups reported more CVD (4.1 to 7.6%) compared to Norwegians (2.9%, p<0.001), despite being younger. Ethnic differences were found for most risk factors irrespective of diabetes status. For subjects not reporting diabetes, the OR for CVD adjusted for age and gender was higher in all the ethnic minority groups (2.6 to 4.1, p<0.001) compared with Norwegians, whereas for subjects with diabetes OR for CVD was only significantly higher compared to Norwegians for the Vietnamese 4.0 (p=0.01).
Conclusion: All ethnic minority groups reported higher prevalence of diabetes and CVD than Norwegians. The excess risk of CVD in ethnic minorities was more profound in subjects not reporting diabetes than in those with diabetes, indicating the need to improve primary prevention of CVD in these groups.

The effect of different glucose values during hospitalisation on one-year outcome after an acute coronary syndrome

A. Melidonis[1], A. Koutsovasilis[1], G. Tsourous[1], A. Nikolaou[1], I. Chrysomallis[1], V. Dragoumanos[1], S. Iraklianou[1], S. Foussas[2];
[1]Diabetes Center, [2]Cardiology Department, Tzaneio General Hospital, Piraeus, Greece.

Background and aims: Elevated glucose at the time of hospital admission is associated with increased mortality rates among patients hospitalized with Acute Coronary Syndrome (ACS). Admission glucose represents only a single measurement in time while in-hospital hyperglycemia during the first days after admission or during the entire ACS hospitalization period is obtained by the use of multiple glucose values. The aim of this study is to evaluate the impact of different glucose values (admission, fasting, postprandial, mean hospitalization glucose and HbA1c) for these patients' first-year outcome.
Materials and methods: 520 patients were admitted to the coronary care unit and discharged February 2006 - October 2007 were included in this longitudinal, prospective, observational, study. First-year end points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Non-diabetic patients went through an OGTT one month after discharge and IGTs were categorized. To evaluate the impact of different glucose measurements on first-year complications after the ACS incidence, separate logistic regression models were performed for each measurement. The accuracy of these logistic regression models in predicting complications for the predetermined time period was assessed using the Receiver- Operating Characteristic (ROC) curves, and their respective areas under the curve (AUC).
Results: Diabetes was previously diagnosed (Group A) in 152 (29.2%) patients, newly diagnosed (Group B) in 57 (10.9%) patients, an IGT (Group C) was observed in 110 (21.1%) patients while 201 (38.8%) were patients with normal glucose regulation (Group D). The incidence of one-year complications was 24.3%, 21.1%, 13.6% and 11.9% in groups A, B, C and D respectively (p=0.014). AUC of ROC curves for the probabilities of the logistic regression models (adjusted for age, gender, smoking, waist circumference, HDL, triglycerides, total cholesterol, metabolic syndrome (NCEP-ATP III) and hypertension) for the admission glucose was 0.697 (p=0.001) 0.627 (p=0.010) 0.601 (p=0.022) and 0.578 (p=0.049) for A, B, C and D Group respectively. AUC for the fasting glucose was 0.632 (p=0.021), 0.581 (p=0.033) for groups A, B respectively. Statistically significant AUC for the postpandial glucose was just for Group A [0.611, (p=0.033)] while significant AUC for the mean value of the glucose during hospitalization was 0.601 (p=0.026) 0.578 (p=0.036) and 0.557 (p=0.048) for Groups A, B and C respectively. AUC for the HbA1c was 0.592 (p=0.033) and 0.522 (p=0.043) for groups A and B respectively, showing no statistical significance as to the outcome of the other two groups.
Conclusion: Admission glucose in ACS incidents shows the most significant correlation with first-year end-points even in normoglycemic patients among different glucose values during hospitalization. The postprandial glucose is related with end-points only in known diabetics while the fasting glucose shows a significant correlation only in diabetic patients. Prolonged hyperglycemia expressed by mean glucose values during hospitalization affects newly diagnosed, known diabetic patients and IGT patients.

1254

Evidence of diastolic dysfunction in NAFLD: A study using tissue Doppler echocardiography

C.K. Wong[1], M.I. Burgess[1], A. Irwin[1], C.J. Pugh[2], K. George[2], P. Richardson[3], D.J. Cuthbertson[1];
[1]Clinical Sciences Centre, University of Liverpool, [2]Liverpool John Moores University, [3]Royal Liverpool and Broadgreen University Hospital Trust, United Kingdom.

Background and aims: Non alcoholic fatty liver disease (NAFLD) is considered the hepatic manifestation of metabolic syndrome and such patients have increased risk of cardiovascular events (myocardial infarction, stroke, coronary revascularisation and cardiovascular death). Recent data suggests that patients with NAFLD had a hazard ratio of 2 for developing a cardiovascular endpoint in 6.5 years. Abnormalities in diastolic function often presage cardiac disease. Diastolic dysfunction may progress to symptomatic heart failure without systolic impairment. The aim of this study is to compare diastolic dysfunction in patients with NAFLD compared with age matched controls using tissue Doppler echocardiography, a method which can measure differential velocities within a region of interest.
Materials and methods: 15 patients with NAFLD and 15 normal controls were recruited. The diagnosis of NAFLD was as per local guidelines. Subjects underwent transthoracic echocardiography using a GE Vivid Q machine (2.5MHz phased array transducer). Colour tissue Doppler loops (3 cardiac cycles) in each of the apical 4-chamber, 2-chamber and long axis imaging planes were acquired triggered to the ECG and saved digitally for subsequent off line analysis by a single experienced operator data who produced the strain and strain rate curves using Echopac V9.01 (GE, Horten, Norway).
Results: The control and NAFLD groups were matched for age, BMI and systolic blood pressure: 50.8±8.6 vs 48.4±13.2 years, 28.1±5.0 vs 28.1±4.9kg/m^2, 126.4±12.8 vs 128.6±8.8mmHg. Nor was there a significant difference in ejection fraction 57.1±12.3 vs 62.4±8.9% or left ventricular mass index 74.1±14.2 vs 79.8±15.1.E/Ea ratio is significantly elevated in patients with NAFLD (table 1). E/Ea ratio is a marker of LA pressure which acts as a surrogate for diastolic dysfunction. Patients with NAFLD showed significant reductions in both diastolic velocities and peak early diastolic strain rate compared with normal controls, supporting the presence of diastolic dysfunction. There is also a non significant trend suggesting patients with NAFLD have reduced systolic velocity and strain.
Conclusion: These results suggest diastolic dysfunction in patients with NAFLD compared with controls. Diastolic dysfunction, left untreated, may

progress to heart failure which may explain the excess cardiovascular events in this group.

Table 1: Tissue doppler results for the left ventricle

	Controls (n=15)		NAFLD (n=15)		p
	mean	sd	mean	sd	
Mean early left ventricular inflow velocity/mean early diastolic myocardial velocity at the septum (E/Ea)	10.5	2.5	13.0	3.1	0.02
Peak systolic myocardial velocity (cm/s)	6.5	.9	5.8	1.2	0.08
Peak early diastolic myocardial velocity (cm/s)	7.9	2.1	6.3	1.8	0.04
Peak late diastolic myocardial velocity (cm/s)	10.1	1.3	7.2	2.9	0.002
Peak systolic strain (%)	22.9	4.4	20.7	3.3	0.14
Peak systolic strain rate (1/s)	1.4	0.4	1.4	0.3	ns
Peak early diastolic strain rate (1/s)	2.4	0.5	1.8	0.4	0.002

Alterations in diastolic function and lipid metabolism occur with the onset of overt hyperglycaemia in women with prior gestational diabetes

Y. Winhofer[1], M. Krssak[2], D. Jankovic[1], L. Bozkurt[1], G. Reiter[3], C. Anderwald[1], G. Pacini[4], S. Trattnig[2], A. Luger[1], M. Krebs[1], A. Kautzky-Willer[1];
[1]Department of Internal Medicine III, Medical University of Vienna, Austria, [2]Department of Radiodiagnostics, Medical University of Vienna, Austria, [3]Siemens Austria, Vienna, Austria, [4]ISIB CNR, Padua, Italy.

Background and aims: Heart failure is still the main cause of death in patients with type 2 diabetes and especially women with diabetes have an increased cardiovascular risk compared to their male counterparts. Since cardiac complications are often present at the time of diagnosis of diabetes mellitus type 2 the question appeared if alterations in cardiac function are already present in prediabetic stages or if the diagnosis of diabetes is often delayed. Since women with prior gestational diabetes (pGDM) display a young, female population at increased risk for developing type 2 diabetes, the aim of this study was to investigate cardiac function via magnetic resonance (MR) imaging in women with pGDM with normal glucose tolerance, impaired glucose tolerance and overt type 2 diabetes as well as in women with no history of gestational diabetes and normal glucose tolerance (CON).
Materials and methods: ^{1}H magnetic resonance imaging of the myocardium, an oral glucose tolerance test for the assessment of glucose tolerance and blood sampling for the measurement of HbA1C and lipid profile were performed in 8 pGDM with normal glucose tolerance (NGT), 6 pGDM with impaired glucose tolerance (IGT), 12 pGDM with type 2 diabetes (DM) and 10 women with no history of gestational diabetes and normal glucose tolerance during pregnancy (CON), who served as controls. The median follow-up period since pregnancy was 10 years.
Results: DM showed a significant reduction of the E/A-ratio compared to IGT (1.09 vs 1.9; p=0.002) as well as a decreased stroke volume compared to all other groups (60.1±14.5 vs 79.47±14.6 ml;p=0.008) and significantly higher triglycerides (p=0.03) and lower HDL-values compared to NGT and CON (CON:64.8±9.2, NGT:66.4±17.6, IGT:53.5±12.8, DM:46.8±12.0; p=0.0047). E/A ratio and stroke volume were inversely correlated with systolic blood pressure (R=-0.6; p=0.002), triglycerides (R=-0.5; p=0.003) and HbA1C (R=-0.5; p=0.001) and positively correlated with HDL (R=0.4; p=0.03). DM were older compared to NGT and IGT, but comparable to CON. There was no difference in BMI between the groups.
Conclusion: According to our results women with overt diabetes are characterized by alterations of diastolic cardiac funtion and lipid metabolism. The latter seems to develop at the prediabetic stage. Hence, early detection of overt hyperglycemia and dyslipidemia in women at high risk should be the primary aim in the prevention of cardiac complications in diabetes mellitus type 2.

1256

Effects of hyperglycaemia and hyperinsulinaemia on cardiac function and lipid metabolism: A magnetic resonance spectroscopy and imaging study

M. Krebs[1], M. Krssak[2], D. Jankovic[1], C. Anderwald[1], G. Reiter[3], S. Trattnig[4], A. Luger[1], Y. Winhofer[1];
[1]Dept.of Internal Medicine III, Medical University of Vienna, Austria, [2]Dept.of Radiodiagnostics, Medical University of Vienna, Austria, [3]Siemens Austria, Vienna, Austria, [4]Medical University of Vienna, Austria.

Background and aims: Diabetic cardiomyopathy is a disease specific entity which is present in patients with diabetes even in the absence of coronary artery disease and arterial hypertension. The pathophysiology of this disease is still unknown. However, recent evidence suggests that increased myocardial lipid accumulation (lipotoxicity) likely contributes to its development. Although our recent investigations confirmed increased myocardial lipid content in patients with type 2 diabetes, we could not find any evidence for cardiac steatosis in prediabetic subjects. Therefore we hypothesized that myocardial lipid accumulation might be linked to overt hyperglycemia .Therefore the aim of this study was to investigate the impact of hyperglycemia and hyperinsulinemia during a 6-h clamp on cardiac function and intramyocellular lipids in vivo by non-invasive magnetic resonance (MR) imaging and spectroscopy.
Materials and methods: Hyperglycemic (~ 200 mg/dl, 6h) clamps were performed in 8 healthy subjects (5 males, 3 females; BMI: 22,8±2,9 kg/m^2; age: 29,7±7,2 a). ^{1}H magnetic resonance imaging and breath movement navigated and ECG triggered localized ^{1}H single voxel MR spectroscopy (TE= 30ms) were used to measure left ventricular dynamic parameters and myocardial lipid accumulation in cardiac septum at baseline and after 6 hours of hyperglycemia.
Results: During hypertglycemia myocardial lipid content increased by 27,7% (p=0.04) and this increase in myocardial lipids was inversely correlated with changes in stroke volume (R=-0.82; p=0.02). Furthermore, a small increase in ejection fraction (+6.2%; p=0.007) was observed.
Conclusion: Our preliminary results suggest that hyperglycemia induces cardiac lipid accumulation in healthy subjects and might lead to impaired diastolic myocardial function.

1257

Are revascularisation procedures in asymptomatic diabetic patients with myocardial ischaemia beneficial? A retrospective study

P. Valensi[1], M. Nguyen[1], K. Takbou[1], S. Cattan[2], B. Chanu[1], I. Banu[1], E. Cosson[1];
[1]Department of Endocrinology, Diabetology, Nutrition, Jean Verdier Hospital, Bondy, [2]Department of Cardiology, Le Raincy Montfermeil Hospital, Montfermeil, France.

Background and aims: Screening diabetic patients for silent myocardial ischemia (SMI) is controversial but some studies have suggested that revascularization may improve the prognosis of the patients with silent coronary artery disease (CAD). The aim was to determine in a retrospective study if coronary revascularization may improve the prognosis of patients with silent CAD.
Material and methods: Between 1992 and 2008, a total of 787 asymptomatic diabetic patients with a normal ECG at rest but with at least another risk factor were screened for SMI by performing a stress myocardial scintigraphy. In the present study we included the 263 patients with SMI (169 men, diabetes duration 14±8 years, nephropathy 45%, hypertension 72%, dyslipidemia 67%, smoking 29%, other artery disease 14%, family history of premature CAD 11%). Coronary angiography was performed in all of them and 93 had silent CAD (1-/2-/3-vessel disease: 49/19/17 patients; and 8 patients with an unknown number of vessel disease). The incidence of a first cardiac event was compared in the patients with SMI but no CAD (group SMI-no CAD, n=171) and in those with SMI and CAD with initial coronary revascularization (group CAD-revascularization: 29 percutaneous coronary intervention (PCI) and 7 coronary artery by pass (CABG)) or without initial revascularization (group CAD-medical, n=56).
Results: The proportion of men was higher in the CAD-revascularization group than in the CAD-medical group (83 vs 54%, p<0.05) with no other clinical or biological significant difference at baseline across both groups. After a mean follow-up of 5.5±4.2 years, 36 cardiac events occurred: 8 cardiac deaths, 23 acute coronary syndromes, 3 secondary coronary revasculariza-

tions, 1 cardiac failure and 1 ventricular fibrillation. The incidence of events differed significantly between the three groups (Kaplan Meier analysis: log rank 23.0, p<0.0001). It was the lowest in the SMI-no CAD group, the highest in the CAD-medical group and intermediate in the CAD-revascularization group. In the patients with 3-vessel disease, the incidence of cardiac events was lower in those who were revascularized by CABG than in those who were medically treated (log rank 6.5, p<0.05).
Conclusion: The cardiac prognosis is poor in the diabetic patients with silent CAD. The data suggest that CABG may improve the prognosis of those with 3-vessel disease.

1258

The role of soluble ST2 in diabetic patients with preserved left ventricular systolic function and the parameters that influence its value
E. Fousteris[1], A. Koutsovasilis[2], A. Theodosis Georgilas[3], S. Matsagos[4], G. Dimitriadis[5], A. Melidonis[2];
[1]First Clinic of Internal Medicine, Tzanio General Hospital, Piraeus, [2]Diabetes Center, Tzanio General Hospital, Piraeus, [3]Cardiology Department, Tzanio General Hospital, Piraeus, [4]Blood Bank service, Tzanio General Hospital, Piraeus, [5]2nd Department of Internal Medicine, Research Institute and Diabetes Center, University of Athens, Medical School, Greece.

Background and aims: Soluble ST2 is a member of the IL-1R receptor family and it has been used in several studies as a sensitive biomarker of cardiac failure. This biomarker has never been studied before in diabetic population, compared to healthy controls. The aim of this study was to find any possible differences of the value of sST2 among diabetic and non diabetic subjects with preserved LV systolic function. The second aim was the revelation of any other biological parameters of diabetic patients that impact on the value of sST2.
Materials and methods: We recruited 106 subjects, 36 healthy and 70 diabetic volunteers that underwent extensive ultrasonographic check of their cardiac function, using the latest revised guidelines of ACC/AHA. All subjects that had an ejection fraction < 50% were excluded. Exclusion criteria were also subjects with history of active malignancy and/or chemotherapy, chronic use of corticosteroids or thiazolinediones and history of autoimmune diseases. We measured all the classical biomarkers (where as blood count, biochemistry, lipidemic profile, hs CRP, Fibrinogen, BNP) and the sST2 with the ELISA technique by using the Presage™ ST2 assay kit by Critical Diagnostics.
Results: Mean age of the total 106 subjects were at 56,45 ± 9,19 years, without any differences between the 2 groups. No difference was observed also at the sex distribution in the groups. The mean value of sST2 in group A (non diabetic controls) was 9,76 ± 5,21, statistically significant lesser than the 13,48 ± 5,75 of group B (diabetic patients) (p=0,017). There was no significant difference on the BNP levels among the 2 groups (group A: 26,08 ± 13,10, group B: 31,36 ± 31,85, p=0,507). Similarly, no statistically significant difference was noticed on the values of hsCRP, Fibrinogen, estimated GFR. In the analysis of all the population, it seems that sST2 value is affected by fasting glucose level (r=0,360, p=0.034), HbA1C (r=0.389, p=0.023) and HDL (r=0.304, p=0.048). The multivariable analysis accrues that HbA1C is an independent correlation factor to the sST2 (β=0.186, p=0.045).
Conclusion: No study until now has focused on the role of sSt2 on diabetic people. In our study we showed that diabetic people with preserved LV systolic function have higher levels of sST2 compared to non diabetic controls. This value seems to be affected by the level of glycemic control (HbA1c), fasting glucose and H.D.L. Further research needs to be done to uncover the underlying pathophysiological mechanisms.

PS 125 Cardiovascular effects of interventions

1259

The impact of smoking cessation on metabolic factors in newly diagnosed patients with type 2 diabetes: a one-year prospective study
C. Voulgari, C. Stathi, A. Kokkinos, K. Makrilakis, N. Katsilambros, N. Tentolouris;
First Department of Propaedeutic and Internal Medicine, Laiko Hospital, Athens, Greece.

Background and aims: Smoking is an independent risk factor for cardiovascular morbidity and mortality. Patients with type 2 diabetes-mellitus (T2DM) are at increased risk for cardiovascular events and smoking cessation is a priority for the prevention of macrovascular and microvascular complications. In the present prospective study we evaluated the impact of smoking cessation on glycaemic control and metabolic factors in subjects with newly-diagnosed T2DM.
Materials and methods: We recruited 193 smokers (96 male/97 female: age 57±7.8 years) with newly-diagnosed T2DM, without macrovascular complications, who were educated to smoking cessation, diet and exercise. A detailed history of smoking habits (years-frequency of smoking, types of tobacco used) was obtained. All subjects were contacted by phone every 2-weeks in the first 2-months and monthly thereafter with emphasis on smoking cessation. Ankle-brachial-pressure index (ABI) was measured by ultrasonography. Demographic, biochemical parameters, insulin-resistance and albumin-excretion-rate (AER) were measured at baseline and 1 year after smoking cessation.
Results: At baseline, smoking habit was associated significantly with younger age [OR, 95% C.I. 1.86 (1.79-1.94)], female gender [1.19 (1.04-1.96)], higher BMI [1.85 (1.73-2.00)], systolic-blood-pressure (SBP) [1.02 (1.00-1.05)], HbA1c [1.97 (1.05-1.99)] and insulin-resistance [1.62 (1.03-2.54)], dyslipidemia (low HDL-cholesterol and/or high triglyceride levels and /or high LDL-cholesterol) [1.96 (1.94-1.99)], higher AER [1.62 (1.00-1.90)] and lower ABI [0.005 (0.00-0.85)]. Marital status was associated with lower odds [0.09 (0.01-0.68)] whereas a higher education level with higher odds of smoking [3.80 (1.02-4.15)]. At the end of the 12-month period, 62.2% (n=120) of the studied population reported successful cessation. Pharmacological interventions for hyperglycaemia, dyslipidaemia and blood-pressure control were not different between the studied groups. Towards baseline, after adjustment for dietary-factors and exercise-level, smoking cessation had the highest contribution in the reduction of HbA1c [0.116 (0.081-0.158], insulin-resistance [0.184 (0.03-0.35)], dyslipidaemia [0.94 (0.82-0.99)], SBP [0.34 (0.32-0.43], AER [0.50 (0.23-0.72)] and increased ABI [0.001 (0.00-0.15)]. No significant differences were found between patients who continued smoking and those who quitted regarding BMI and waist-circumference. Microalbuminuria was reduced by 38% in subjects quitting smoking and by 16% in those who continued smoking (P<0.001).
Conclusion: Smoking cessation strategies are effective in subjects with T2DM. Smoking cessation improves glycaemic control and lipid profile and reduces blood-pressure and microalbuminuria. Stricter counselling and interventions for quitting smoking are warranted in patients with T2DM for the prevention of microvascular and macrovascular complications.

Achievement of specified lipid and hs-CRP levels with ezetimibe/simvastatin vs atorvastatin in metabolic syndrome patients with and without atherosclerotic vascular disease
J. Rosen[1], J. Robinson[2], H.-H. Parving[3], C. Ballantyne[4], S. Grundy[5], W. Hsueh[6], J. Lin[7], A. Shah[7], M.E. Hanson[8], A.M. Teshakovec[8];
[1]Clinical Research of South Florida, Coral Gables, USA, [2]Departments of Epidemiology & Medicine, University of Iowa, Iowa City, USA, [3]University Hospital of Copenhagen, Denmark, [4]Baylor College of Medicine and Methodist DeBakey Heart and Vascular Center, Houston, USA, [5]University of Texas Southwestern Medical Center, Dallas, USA, [6]Diabetes Research Center, The Methodist Hospital Research Institute, Houston, USA, [7]Merck & Co, Inc, Rahway, USA, [8]Merck & Co, Inc, North Wales, USA.

Background and aims: Atherosclerotic vascular disease (AVD) and metabolic syndrome (MetS) are each associated with an increased risk of CHD. In-

tensive treatment of modifiable factors associated with AVD and MetS, such as dyslipidemia, is recommended by treatment guidelines, including achievement of specific LDL-C, non-HDL-C and Apo B levels. The aim of this *post hoc* analysis was to assess the proportion of patients with and without AVD treated with ezetimibe/simvastatin combination therapy versus atorvastatin reaching specified lipid and hs-CRP levels.

Materials and methods: Adult patients (N=1143) with MetS and hypercholesterolemia were randomized to ezetimibe/simvastatin combination tablet 10/20 or 10/40 mg or atorvastatin 10, 20, or 40 mg for 6 weeks. Prespecified dose comparisons were ezetimibe/simvastatin 10/20 mg vs atorvastatin 10 mg or 20 mg and ezetimibe/simvastatin 10/40 mg vs atorvastatin 40 mg.

Results: The rates and ratios of the predictive odds of achieving specified levels and 95% confidence intervals are presented in the table. Significantly more patients without AVD achieved the single LDL-C, non-HDL-C and Apo B levels and the combination of these three levels with ezetimibe/simvastatin vs atorvastatin for the specified dose comparisons, except in the ezetimibe/simvastatin 40 mg vs atorvastatin 40 mg dose comparison. Significantly more patients with AVD achieved the single LDL-C and non-HDL-C levels and the combined triple levels with ezetimibe simvastatin vs atorvastatin at all dose comparisons, and the single Apo B level only with the ezetimibe/simvastatin 10/20 mg vs atorvastatin 10 mg comparison. In both subgroups achievement of hs-CRP<2.0 mg/L was similar with both treatments at all dose comparisons.

Conclusions: Compared with atorvastatin at prespecified dose comparisons, treatment with ezetimibe/simvastatin combination resulted in significantly more MetS patients with or without AVD achieving most of the specified lipid levels and the combined lipid endpoints. Clinical benefit from reduction in cardiovascular outcomes through treatment with ezetimibe/simvastatin or through hs-CRP lowering has not been proven.

Table

Patients without AVD*	LDL-C<100 mg/dL	non-HDL-C <130 mg/dL	Apo B<90 mg/dL	Triple target†	hs-CRP<2.0 mg/L

Statin therapy and serum transaminases among patients with type 2 diabetes and hepatitis C

E.D. Rusu[1], G. Radulian[2], F. Rusu[1], V. Stoica[2], M. Jinga[2], A.D. Dragomir[3], G. Enache[3], D. Cheta[4];
[1]Healthy Nutrition Foundation, [2]University of Medicine Carol Davila, [3]Nutrition, diabetes, Healthy Nutrition Foundation, [4]Nutrition, diabetes, National Institute of Diabetes Nutrition and Metabolic Diseases, Bucharest, Romania.

Background and aims: Statins are the most efficacious drugs for decreasing low-density lipoprotein cholesterol levels; they reduce both primary and secondary cardiovascular risk in the general population. The objective of this study was to determine the effect of statin therapy (atorvastatin) on serum aspartataminotransferase and alaninaminotransferese levels in patient with type 2 diabetes (T2DM) and hepatitis C. However, less is known about the safety of statin use in patients with liver disease.

Materials and methods: We selected 64 patients with type 2 diabetes mellitus and chronic hepatitis C who are treated with atorvastatin, 20 mg for 6 month. We evaluated body weight, blood pressure, liver enzymes, lipids, adipocytokines (adiponectin, leptin, resistin, TNFalfa, IL-6), insulin resistance (by Homeostasis model assessment - HOMA-IR) at baseline, 1 and 6 months. The liver fibrosis was non-invasively assessed using the Forns index; a value < 4.2 excludes liver fibrosis and a value > 6.9 is a predictor for significant fibrosis.

Results: Plasma triglycerides and cholesterol decreased (p<0.05), HDL-cholesterol and HOMA-IR increased (p<0.05), after 6 months. Aspartataminotransferase and alaninaminotransferese increased but we did not find significant statistically differences (median increased was 15.6 U/L for ALT and 7.2 U/L for AST). Forns index decreased at 6 months (p=0.048). Atorvastatin treatment had no effect on plasma adiponectin (p=0.569) but we observed reducing of leptin and resistin level (p=0.032 respectively p=0.0048). TNFalpha and IL-6 decreased but not significant statistically.

Conclusion: Among patients with hepatic C no significant elevation of liver enzymes during statin treatment was observed. Statin therapy should not be stopped or contraindicated in this patient population; however, more prospective clinical trials are needed to confirm the safety and efficacy.

Effect of nicotinic acid on combined hyperlipidaemia: A kinetic study on reverse cholesterol transport in humans

M. Krempf, Y. Zair, M. Chetiveau, L. Flet, T. Magot, K. Ouguerram;
Clinique d'endocrinologie, Institut du Thorax, Nantes, France.

Nicotinic acid improves the combined dyslipidemia frequently observed in patients with type 2 diabetes or metabolic syndrome. The highest treatment increase of HDL-C is observed with this drug but the underlying mechanisms are unclear. The aim of this study was to give further insights on the effect of nicotinic acid in humans by using a new dual stable isotope technique to estimate the cholesterol transport and metabolism in HDL and other lipoproteins. We recruited 8 patients with combined hyperlipidemia submitted to 8 week treatment with LAR nicotinic acid (2 g/d) associated with aspirin (300 mg/d). The patients were submitted before and at the end of the treatment to a dual infusion of 2H3 leucine and 13C2 acetate. The tracer/trace ratio was analyzed by mass spectrometry in Apo B100, Apo AI and cholesterol (free and esterified) in VLDL, IDL, LDL and HDL. The compartmental model to analyze the data was developed on SAAM II. With LAR nicotinic acid triglycerides declined (2.21±0.67 vs 1.19±0.62, p<0.05) as total cholesterol (2.15±0.47 vs 1.80±0.38, p<0.05) and LDL-C (1.28±0.45 vs 1.03±0.29, p<0.05) while HDL-C increased (0.41± 0.13 vs 0.49±0.10, p<0.05). There was no change on hepatic ApoB100-VLDL production but conversion rate of ApoB100-VLDL to ApoB100-LDL increased (0.091±0.039 h-1 vs 0.123h-1 ±0.039, p<0.05). There was no significant change on ApoAI-HDL kinetics. An increase of free cholesterol esterification was observed within HDL (0.13±0.045h-1 vs 0.23±0.13h-1, p<0,05)and an increase of esterified cholesterol catabolism in HDL (0.049± 0.014 vs 0.074± 0.036 mg.kg-1. h-1, p<0,09)associated with a decrease of esterified cholesterol transfer to VLDL and LDL(0.45± 0.11 vs 0.32± 0.14 h-1, p<0,05) through CETP. We concluded that LAR nicotinic acid decreased triglycerides by increasing vascular lipolysis and increased reverse cholesterol transport by increasing cholesterol esterification and catabolism

within HDL. The increase oh plasma HDL-C is mainly related to a decrease (30 %) of CETP cholesterol transfer.

Study of apparent aspirin resistance in 100 consecutive patients with type 2 diabetes in primary cardiovascular prevention

A. Decaudain[1], S. Legal[1], C. Baralon[1], N. Lamrache[1], S. Charriere[1], L. Groisne[1], M. Hanss[2], M. Moulsma[3], P. Moulin[4];
[1]Endocrinology, cv hospital, Lyon Bron, [2]hemostasis, GHE, Lyon Bron, [3]Biochemistry, HEH, Lyon, [4]Endocrinology, HCL/univ Lyon1, Lyon Bron, France.

Background and aims: Occurrence of aspirin resistance in type 2 diabetes (D2) is controversial. It has been considered as a cardiovascular risk factor whatever the underlying mechanism. However it is difficult to distinguish authentic platelet resistance to the inhibitory effect of acetyl salicylic acid from non compliance. The aim of this study was to establish the prevalence of aspirin resistance in type 2 diabetic patients in primary cardiovascular prevention, submitted to multiple therapies and consequently more likely to be inobservant.
Materials and methods: 100 consecutive aspirin treated D2 patients in primary cardiovascular prevention were included in an observational prospective mono centric study. Patients were 65±8 years old, had D2 for 16±8 years, HbA1c = 7.7±1.1%, and were treated by low dose of aspirin (75 - 325 mg /d, mean 120±6 mg/d). Platelet *a*ggregation was assessed by arachidonic acid (0.5 mg/ml) on platelet rich plasma. Normal platelet function was established in 55 D2 patients not treated by aspirin (CTRL), (57±11 years old, D2 for 11±7 years, HbA1c 7.6±1.2%). Blood was drawn in the fasting state, in the morning, before any treatment administration.
Results: Mean aggregation level in CTRL D2 was 81.3±13.7%. 83% of D2 patients treated by low dose of aspirin had an aggregation level below 60%, cut off corresponding to the lowest aggregation level found in CTRL D2. All these aspirin sensitive D2 patients had an aggregation level lower than 25% (mean 6.3±7.9%). In univariate analysis, no criteria (age, sex, duration of diabetes, micro-angiopathic complications, smoking, number of pills taken daily¼) was associated with the occurrence of unaltered aggregation function under aspirin treatment. In the 17 D2 patients with apparent resistance, 6 (35%) admitted to have omitted to take aspirin the day before assessment of platelet function. In the 11 remaining patients, 6 were tested again after giving special advice to take aspirin the day before. Platelet aggregation level was found below 25% in all these patients upon this second test.
Conclusion: In the present study, 17% of D2 patients in primary cardiovascular prevention had an apparent aspirin resistance. However the second test showing the expected platelet aggregation inhibition suggests that non compliance plays a major role in the occurrence of apparent resistance to aspirin.

Metformin use among patients with type 2 diabetes and renal impairment

S.X. Sun[1], M. Bron[1], R. Spanheimer[2], S. Hudgens[1], R. Ramalakar[1], A. Hariri[2];
[1]Takeda Pharmaceuticals International, Inc., Deerfield, [2]Takeda Pharmaceuticals North America, Inc., Deerfield, LYON BRON.

Background and aims: The most prescribed oral antidiabetic medication for treating type 2 diabetes (T2D), metformin is contraindicated in T2D patients with renal impairment due to risk of lactic acidosis.
Materials and methods: Metformin use among T2D patients with renal impairment was examined with a retrospective analysis of the I3 Innovus database from May 1, 2000 to December 31, 2008. T2D patients (ICD-9 codes 250.x0 or 250.x2) with renal impairment (serum creatinine concentration ≥1.5 mg/mL in males and ≥1.4 mg/mL in females) were identified. Stage of chronic kidney disease (CKD) was based on estimated glomerular filtration rate (eGFR), calculated from serum creatinine, age and gender (using MDRD formula). The index date was the same or later diagnosis date of T2D or CKD. The baseline period was 6 months prior to index date, and the follow-up period was 12 months after index date. Patients were 18 years or older and had at least one serum creatinine value and at least one claim for antidiabetic medications during the study period. Patients with type 1 diabetes were excluded.
Results: After applying all inclusion and exclusion criteria to 1.7 million T2D patients, a total of 1,985 patients were identified with CKD and T2D; the majority (76%) had stage 3 CKD (table). Mean age was 61 years, and two-thirds were male. In the follow-up period after diagnosis of T2D and renal impairment, 666 (34%) were prescribed metformin. Metformin use was highest in CKD stage 2, followed by stages 3 and 5 (table). Patients <65 years more often received metformin than those ≥65 years (37% vs. 27%, p<0.0001). Metformin use between female (34%) and male patients (33%) was similar (p=0.8175).
Conclusion: Metformin was maintained in T2D patients with varying degrees of renal impairment including severe kidney disease and kidney failure despite contraindications for use. Further studies are needed to investigate risk of lactic acidosis and glycemic control in this at-risk population.

Table:

Stages of CKD	Group 1: Patients with CKD and T2D (n=1,985)	Group 2: Patients in Group 1 on metformin [34% (666/1,985)]
2 mild (eGFR 60-89)	12% (235)	46% (108/235)
3 moderate (eGFR 30-59)	76% (1,517)	35% (525/1,517)
4 severe (eGFR 15-29)	9% (179)	9% (17/179)
5 renal failure (eGFR < 15)	3% (54)	30% (16/54)

Pioglitazone in addition to metformin improves erythrocyte deformability in patients with type 2 diabetes mellitus. Results from the PIOfix study

S. Forst[1], M. Löbig[1], U. Lehmann[2], C. Hohberg[1], C. Friedrich[1], W. Fuchs[2], A. Pfützner[1], T. Forst[1];
[1]Institute for Clinical Research and Development, Mainz, [2]Medical Department, Takeda Pharma, Aachen, Germany.

Background and aims: Changes in hemorheology and blood viscosity were shown to contribute to the development of micro- and macrovascular complications. In patients with diabetes mellitus, increased hematocrit levels and reduced erythrocyte deformability are considered to impair microvascular blood flow and to reduce tissue oxygenation. In recent studies, treatment with pioglitazone was shown to improve endothelial function and to improve the overall risk for vascular complications in patients with type 2 diabetes mellitus. The aim of this study was to compare the effect of adding pioglitazone or glimepiride to metformin treatment on erythrocyte deformability in patients with type 2 diabetes mellitus (T2DM).
Materials and methods: This two arm, parallel study, covered 23 metformin treated T2DM patients (16 male, age: 57.2±10.7 years; BMI 32.7±4.3 kg/m^2) with an HbA1c above 6.5%. Patients were randomized to receive either 15 mg Pioglitazone (PIO) bid. or 1 mg Glimepiride (GLIM) bid. in combination with 850 mg Metformin bid. for 6 months. Blood samples were taken for the measurement of fasting glucose, HbA1c, fasting insulin, intact proinsulin, adiponectin, and heamatocrit (Hct). In addition, the erythrocyte elongation index (EI) was measured using laserdiffractoscopy (Rheodyn SSD, Myrenne GmbH, Roetgen, Germany) at a shear stress range from 0.3 Pa to 60 Pa.
Results: Both treatments significantly improved HbA1c levels (PIO -0.9±0.8%; GLIM -0.6±0.4%; p<0.05 respectively) and end up in comparable HbA1c levels after 6 months (PIO 6.5 ± 1.2; GLIM 6.2 ± 0.4) Treatment with PIO reduced fasting insulin (-8.2±15.1 mU/L; p=0.097), and intact proinsulin levels (-11.3±9.2 pmol/L; p<0.05), and increased adiponectin levels (8.1±4.6 µg/mL; p<0.05). Hkt slightly decreased during PIO treatment (-1.3±2.3%; p=0.09). No significant changes in these parameters could be observed during GLIM treatment. As shown table 1, PIO improved the EI, resulting in a significant improvement at all physiological shear stress ranges (0.6 to 6.0 PA). At a physiological shear stress rate of 1.2 Pa, the improvement in EI correlated with the increase in adiponectin levels (r=0.74; p<0.0001), and inversely with intact proinsulin levels (r=-0.47; p<0.05).
Conclusion: This is the first study showing an improvement in erythrocyte flexibility during treatment with pioglitazone which was correlated to an increase in adiponectin and a decrease in intact proinsulin levels, but independent from glycaemic control.

Change in erythrcyte elongation index (EI; * p<0.05 vs baseline; $ p<0.05 PIO vs. GLIM)								
Shear stress (PA)	0.30	0.60	1.20	3.00	6.00	12.00	30.00	60.00
GLIM (EI)	-0.4± 1.7	-0.5±1.1*	-1.1±2.5*	-1.5±3.1	-2.1±3.8	-1.3±2.9*	-1.3±3.5	-1.3±3.9
PIO (EI)	1.3±2.1	2.4±1.3*,$	3.2±2.2*,$	3.3±2.8*,$	3.1±2.9*,$	2.7±2.8$	2.5±2.6	2.7±2.6

1266

Examination of the cardiovascular safety of pramlintide with a meta-analysis of five controlled clinical trials in patients with type 2 diabetes mellitus

S. Chen, C. Burns, K. Shan, H. Dong, K. Herrmann, S. Miller, I. Yushmanova;
Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Pramlintide was approved by the US FDA in 2005 as an adjunctive treatment for patients with diabetes who use mealtime insulin with or without oral antihyperglycaemic drugs who have not achieved desired glucose control. The FDA recently issued guidance on the type of evidence required to demonstrate that a new type 2 diabetes therapy is not associated with unacceptable cardiovascular risk. In the absence of guidance for currently marketed antidiabetic therapies, the cardiovascular risk of pramlintide was examined following the guidance for new therapies.
Materials and methods: Analysis of an integrated database of 5 randomised controlled type 2 diabetes trials (16 to 52 weeks) compared relative risk (RR) and hazard ratio (HR) of cardiovascular events with pramlintide vs a pooled comparator treated with either placebo or rapid-acting insulin. Background therapies included at least one type of insulin and in some cases oral antidiabetic agents. The primary endpoint was primary major adverse cardiovascular events (MACE) including cardiovascular mortality, myocardial infarction, stroke, acute coronary syndrome hospitalisation, and urgent revascularisation procedures. Subset MACE analysis used narrower criteria including only cardiovascular mortality, myocardial infarction, and stroke, while SMQ MACE included all Standardised MedDRA Query terms for these events. The broader secondary endpoint included the primary endpoint terms plus arrhythmia, heart failure, and mechanical-related events.
Results: The population included 1434 pramlintide and 582 pooled comparator subjects treated for a total of 960 and 359 patient-years, respectively. Demographics were comparable between groups (mean age 56-57 y, 52-54% M, BMI 32-33 kg/m^2, HbA_{1c} 9.0-9.1%). RRs and HRs between pramlintide and pooled comparator ranged from 0.86 to 1.11, depending on the endpoint and analysis method used. Corresponding 95% upper CI limits were below or close to the FDA-specified 1.8 threshold, suggesting no unacceptable increase in cardiovascular risk.

	Primary MACE		Subset MACE		SMQ MACE		Secondary CV	
	Ratio	(95% CI)	Ratio	(95% CI)	Ratio	(95% CI)	Ratio	(95% CI)
RR (Mantel-Haenszel)	0.86	(0.55, 1.34)	0.90	(0.46, 1.76)	1.10	(0.62, 1.96)	1.03	(0.74, 1.43)
HR (Cox)	0.88	(0.56, 1.38)	0.92	(0.47, 1.78)	1.11	(0.62, 1.99)	1.05	(0.74, 1.49)
HR (Andersen-Gill)	0.93	(0.62, 1.38)	0.95	(0.50, 1.81)	1.10	(0.64, 1.86)	0.92	(0.69, 1.21)

In addition, study of postmarketing reports has not revealed evidence of a signal for cardiovascular risk.
Conclusion: Based on these analyses, there appears to be no increased risk of cardiovascular adverse events associated with pramlintide treatment. However, interpretation of this type of analysis has the following caveats: these trials were not designed to assess cardiovascular outcomes, events were adjudicated retrospectively after unblinding, the number of cardiovascular events was small, and the duration of the trials was ≤52 weeks.

1267

Therapeutic effects of a selective estrogen receptor modulator (SERM) on bone and lipid metabolism in postmenopausal type 2 diabetic patients

H. Mori, Y. Okada, Y. Tanaka;
The First Department of internal medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan.

Background and aims: Diabetic patients are at risk of bone fracture due to poor bone quality, despite the preservation of bone mineral density, therefore management should include control of osteoporosis and vascular events as well as blood glucose. Raloxifene, a selective estrogen receptor modulator, prevents bone mass reduction and vertebral bone fractures in postmenopausal women, improves bone quality and prevents atherosclerosis and breast cancer. We investigated its effects on not only bone but also lipid, and glucose metabolism in postmenopausal patients with type 2 diabetes.
Materials and methods: Subjects were 144 female patients with type 2 diabetes who were younger than 80 years and have been menopausal for at least 2 year. The study was a randomized trial and subjects were assigned to one of 3 groups: No medication; 1 μg alfacalcidol daily; or 60 mg raloxifene daily. Outcomes were measured at baseline and at 6 and 12 months, including serum N-telopeptide (NTx), bone-specific alkaline phosphatase (BAP), homocysteine, TC, HDL-C, LDL-C, TG, HbA1c, fasting blood glucose, insulin, and HOMA-R. The primary outcome of the study was changes in LDL-C at 6 months and secondary outcome was serum NTx, BAP, homocysteine, and HbA1c at 6 and 12 months.
Results: Glucose metabolism was unchanged in all 3 groups. Regarding bone metabolism, both NTx and BAP were reduced at 6 months and further reduced at 12 months in the treatment groups (alfacalcidol group, p=0.001; raloxifene group, p=0.000, compared with baseline). These effects were most remarkable in the raloxifene group. Concerning lipid metabolism, LDL-C at 6 months, a major evaluation item, was significantly reduced in the raloxifene group only (p=0.029). Thus, this study meets the primary outcome by the treatment with raloxifen. HDL-C was elevated in the alfacalcidol group (p=0.007) whereas TG tended to decrease in the raloxifene group. Homocysteine, a bone quality marker, was significantly reduced in the raloxifene group at both time-points (p=0.001). There was no correlation between the rate of improvement of LDL-C and changes in markers of bone metabolism or of bone quality. Multivariate analysis identified TC, HDL-C, and the percent change of TG, but not markers of bone metabolism or quality, as significant determinants of the raloxifene-induced change in LDL-C.
Conclusion: Raloxifene improved lipid metabolism, especially significantly reduced LDL-C at 6 months after the treatment, and reduced homocysteine in postmenopausal type 2 diabetic patients. It has been suggested that this agent could improve defective crosslinks related to bone quality. In type 2 diabetic patients, poor bone quality is linked to increased risk of bone fracture. Since raloxifene improves bone quality as well as lipid metabolism, it is considered useful for all-round health care of postmenopausal type 2 diabetic patients.

Effects of early detection and intensive treatment on peripheral arterial disease - ADDITION Denmark

M. Charles[1], D.R. Witte[2], N. Ejskjaer[3], K. Borch-Johnsen[2], T. Lauritzen[1], A. Sandbaek[1];
[1]Dept of General Practice, School of Public Health, Aarhus, [2]Steno Diabetes Center, Gentofte, [3]Dept of Endocrinology, Aarhus University Hospital, Denmark.

Background: Peripheral arterial disease (PAD) is a marker of systemic atherosclerotic disease and an independent risk factor for foot ulcers and amputations. Measurement of ankle brachial index (ABI) is widely used in the diagnosis of PAD. People with diabetes have an increased risk of developing PAD. Prevalence among diabetic individuals aged over 50 years is estimated to be 29%. Evidence exists on treatment of these patients but there is no evidence on treatment or prevention of PAD in people with screen detected diabetes. Our aim was to study the effect of intensive multifactorial treatment and routine care on PAD in persons with screen detected diabetes in a cluster randomized controlled study.
Methods: We recruited 466 individuals with screen-detected diabetes identified through a screening programme in 87 general practices in the Danish arm of the ADDITION Study. Practices were randomized to intensive treatment (IT) or routine care (RC) before initiation of the screening programme. Individuals in the IT practices (45 practices) received a multi-factorial treatment programme including lifestyle advice (concerning diet, physical activity, medication adherence, and smoking cessation), prescription of aspirin and stepwise increases in pharmacological treatment of blood pressure, glucose and lipids according to strict targets. The RC group (42 practices) were offered treatment according to national guidelines. Anthropometric measures and blood samples were collected at baseline and at five year follow-up. At follow-up ABI was measured according to a standardized protocol. ABI was calculated using the highest blood pressure in each foot divided by the highest blood pressure in either arm. An ABI of <0.9 in either leg was considered "abnormal". A X^2 test was used to assess the hypothesis of no difference in prevalence of PAD between the IT and RC group at follow-up. Logistic regression, accounting for the cluster design, was used to calculate the odds of ABI<0.9 in the IT compared to the RC group.
Results: Baseline characteristics are shown in Table 1. The IT group had a prevalence of abnormal ABI in either leg of 7% (4; 10) compared to 9% (4; 13) in the RC group (p=0.43). The odds ratio of ABI<0.9 in IT compared to RC was 0.76 (0.38; 1.52), p=0.43.
Conclusion: The prevalence of PAD 5 years after a screen-detected diagnosis of diabetes was lower in the Danish arm of the ADDITION trial compared to cohorts of people with known diabetes. This could indicate that screening for diabetes identifies people at an earlier stage in the trajectory of PAD and/or that general diabetes prevention and treatment has improved significantly over the past decade. We did not find that intensive multi-factorial treatment in general practice led to a significant reduction in the prevalence of PAD compared to routine care as recommended by national guidelines.

Table 1 - Baseline Characteristics

	Routine	Intensive
No. of Patients	171	295
Male	57.9%	56.7%
Age (yr)	59.0 (7.0)	59.3 (6.6)
HbA1c	6.4 (1.1)	6.4 (1.4)
Systolic BP (mmHg)	145.1 (17.6)	144.4 (18.5)
Body Mass Index	30.4 (5.43)	30.3 (5.12)
Waist (cm)	103.1 (13.9)	103.3 (13.0)
Total Cholesterol (mmol/l)	5.82 (1.19)	5.64 (1.10)
HDL (mmol/l)	1.37 (0.32)	1.38 (0.37)
Triglycerides	1.7 (1.3)	1.6 (1.0)
Smoking Current	33.7%	31.3%

The association between long term glycaemia and arterial stiffness is detectable with HbA_{1c} but not advanced glycation end-products in people with diabetes risk. The ADDITION-PRO study

N.B. Johansen[1], S.S.S. Rasmussen[2], N. Wiinberg[3], D. Vistisen[1], D.R. Witte[1];
[1]Steno Diabetes Center A/S, Gentofte, [2]Department of Endocrinology, Hvidovre University Hospital, [3]Department of Clinical Physiology, Frederiksberg Hospital, Denmark.

Background and aims: Increased arterial stiffness is one of the initial steps in the development of atherosclerosis. Long term exposure to hyperglycaemia is associated with arterial stiffness. Glycated proteins such as haemoglobin (HbA_{1c}) and advanced glycation end-products (AGE) reflect glycaemia during a longer period. HbA_{1c} is the frequently used assessment of long term exposure to glycaemia and is known to be associated with arterial stiffness. However, it is unknown whether the non-invasive assessment of AGE can detect the same association. We aimed to study how strongly HbA_{1c} and AGE are associated with arterial stiffness in a population at high diabetes risk.
Materials and methods: A Danish population at high diabetes risk originally identified through a stepwise screening programme was invited for a health examination in 2009 including assessments of HbA_{1c} and AGE by non-invasive skin autofluorescence. Plasma lipids, blood pressure, height, weight, and carotid-femoral pulse wave velocity (PWV) as an assessment of arterial stiffness were measured. Information of antidiabetic treatment and smoking was self-reported. Individuals on antidiabetic medication were excluded in the analysis. The effect of HbA_{1c} and AGE on PWV was assessed through linear regression models adjusted for age, sex, and pulse pressure, and furthermore adjusted for BMI, smoking, HDL cholesterol, and triglycerides. The standardized regression coefficients were compared.
Results: 378 individuals (mean age 66.2 years (SD: 6.2), 57% men, mean BMI 27.7 kg/m^2 (SD: 4.4), mean HbA_{1c} 5.9% (SD: 0.4), mean AGE 2.25 arbitrary units (SD:0.52)) are included in the analysis. HbA_{1c} was associated with PWV in the model adjusted for age, sex and pulse pressure (Table 1). This association remained significant after further adjustments. AGE was not associated with PWV at a statistically significant level.
Conclusion: Among individuals at high diabetes risk HbA_{1c} but not AGE measured by a non-invasive method is associated with arterial stiffness. These differences in associations could be explained by the high risk population, and that HbA_{1c} reflects a shorter period of glycaemia than AGE. The other explanation could be that HbA_{1c} is a more precise measurement of long term glycaemia than AGE measured by skin autofluorescence.

Table 1 Change in PWV (m/s) per 1 SD increase in the variable

	PWV (95% CI)		
	Model 1	Model 2	Model 3
HbA_{1c}	0.45 (0.25;0.65)	0.34 (0.13;0.55)	0.31 (0.10;0.52)
AGE	0.16 (-0.05;0.37)	0.10 (-0.11;0.30)	0.06 (-0.16;0.27)

Model 1: Adjustment for age, sex and pulse pressure
Model 2: Model 1 + BMI
Model 3: Model 2 + smoking, HDL cholesterol, and triglycerides

Increased chemerin levels are associated with peripheral arterial occlusive disease and increased urinary albumin excretion rate in type 2 diabetic patients

F. Hoellerl[1], J.M. Brix[1], G.-H. Schernthaner[2], G. Schernthaner[1];
[1]Department of Medicine I, Rudolfstiftung Hospital, Vienna, [2]Department of Medicine II, Medical University Vienna, Austria.

Background and aims: Chemerin is a recently discovered adipokine that regulates adipocyte differentiation and modulates chemotaxis and activation of dendritic cells and macrophages. Chemerin was found to be associated with obesity, insulin resistance and the metabolic syndrome. In addition, recent studies have demonstrated that chemerin has angiogenetic properties. Given the convergence of adipocyte and macrophage function, chemerin may provide an interesting link between obesity, inflammation and atherosclerosis in humans. Thus, the aim of our study was to determine whether

serum chemerin levels are associated with vascular disease and urinary albumin excretion rate in type 2 diabetic patients.
Materials and methods: Serum Chemerin levels were determined in 128 patients with Type 2 diabetes mellitus (T2DM) and different levels of albuminuria (54 with normoalbuminuria (NA), 45 with microalbuminuria and 29 with macroalbuminuria (MA)) as well as in 28 healthy control subjects (CO). Mean Age of the patients was 66±11 years and mean duration of diabetes was 13±8 years. Chemerin was measured by an ELISA (BioVendor, Heidelberg, Germany). Within the T2DM patients 32 patients had a history of peripheral arterial occlusive disease (PAOD), 26 with coronary heart disease, 11 with stroke and 57 with any cardiovascular disease (CVD).
Results: Circulating Chemerin levels are significantly elevated in diabetic patients compared to CO (240.7±77.5 vs 175.6±46.5 ng/ml, p<0.001). In the diabetic patients, serum chemerin levels are significantly associated with urinary albumin excretion rate (UAE, mg/24h; p=0.001). The highest chemerin levels were observed in patients presenting with MA (290.9±84.5 vs 223.1±53.9 ng/ml in NA, p<0.001). In univariate regression analysis of all quantitative variables chemerin was significantly associated with BMI (p=0.009), HbA1c (p=0.019), creatinine (p<0.001), estimated glomerular filtration rate (p=0.002), age (p<0.001) and UAE (p=0.001). The multivariate model revealed UAE (β=0.341, p=0.001), age (β=0.229, p=0.029) and BMI (β=0.231, p=0.028) as predictors of chemerin.Chemerin levels were significantly higher in patients with PAOD versus those without PAOD (264.6±74.9 vs. 217.0±72.5 ng/ml, p=0.002) and in those with any CVD vs those without (255.3±71.6 vs. 208.0±70.5 ng/ml, p<0.001), but did not differ between patients with or without history of myocardial infarction and stroke.
Conclusion: These are the first findings demonstrating that chemerin levels are significantly increased in T2DM patients presenting with PAOD, the most advanced vascular disease in diabetic patients, but not in those with a history of myocardial infarction or stroke. The strong relationship between chemerin and urinary albumin excretion rate could be of clinical relevance in particular since proangiogenic properties were recently found for this adipokine.

1271

Severe peripheral arterial obstructive disease predicts cardiovascular events in type 2 diabetes mellitus: Is there a gender difference?
K. Bonomo, M. Chirio, M. Secchi, P. Poy, A. Pagliarino, M. Trovati, F.L. Cavalot;
Dept of Clinical and Biological Sciences, Faculty of Medicine San Luigi Gonzaga, University of Turin, Orbassano (TO), Italy.

Background and aims: Peripheral Arterial Obstructive Disease (PAOD) predicts cardiovascular (CV) events both in the general and in the diabetic population: aim of the present study is to evaluate whether this predictive power is different in men and women affected by Type 2 diabetes mellitus (T2DM).
Materials and methods: We examined all Type 2 diabetic patients submitted to revascularization procedures (mainly percutaneous angioplasty) because of severe PAOD at our Unit from 1997 to 2009: 50 women and 87 men (identified as "Cases"). Each of them was associated with a control subject matched for gender, age, diabetes duration and lengths of follow-up at our Unit, but without PAOD (identified as "Controls"). In Cases and Controls, we evaluated: a)CV risk factors at the entry in the study (i.e., in Cases at the time of revascularization procedure and in Controls at a corresponding time period); b)the first fatal or non fatal coronary or cerebral vascular event and total and CV mortality during the follow-up. By Cox analysis, we calculated the Hazard Ratios (HR) for the first CV event, CV and total mortality.
Results: In Cases, women differed from men for age (73.8±7.5 vs 69.4±8.8 years, p< 0.0001) and diabetes duration (21.7±11.8 vs 16.4±10.0 years, p<0.0001); similarly in Controls (age 73.7±8.3 vs 69.6±8.3 years, p<0.0001, diabetes duration 21.4±11.8 vs 16.1±10.3 years, p<0.0001). Smoking habit (actual or previous) was present in 41.4% of men Controls vs 88.5% of men Cases and in 4% of women Controls vs 44% of women Cases. CV events occurred in 16/50 (32%) women Cases vs 7/50 (14%) women Controls, and in 33/87 (37.9%) men Cases vs 18/87 (20.7%) men Controls. CV mortality occurred in 16/50 (32%) women Cases vs 6/50 (12%) women Controls and in 26/87 (29.9%) men Cases vs 10/87 (11.5%) men Controls. Total mortality occurred in 23/50 (46%) women Cases vs 10/50 (20%) women Controls, and in 34/87 (39.1%) men Cases vs 17/87 (19.5%) men Controls. HR (and C.I.) of Cases vs Controls corrected for smoking habit were: a)for CV events, 3.177 (1.126-8.967, p=0.029) in women and 3.505 (1.666-7.373, p=0.001) in men; b)for CV mortality, 3.261 (1.169-9.094, p=0.024) in women and 3.303 (1.281-8.521, p=0.013) in men; c)for total mortality, 3.122 (1.352-7.210, p=0.008) in women and 2.818 (1.301-6.105, p=0.009) in men. After correction for HbA1c, serum creatinine, LDL-cholesterol, HDL-cholesterol, triglycerides and smoking habit, HR for CV events were 7.71 (2.101-28.289, p=0.002) in women and 3.513 (1.423-8.676, p=0.006) in men. HR conferred by male vs female gender adjusted for age, diabetes duration and smoking habit were: a) for CV events, 3.565 (1.222-10.403, p=0.020) in Controls and 0.867 (0.439-1.710) in Cases; b) for CV mortality, 3.752 (0.912-15.40, p=0.067) in Controls and 0.932 (0.448-1.939) in Cases; c) for total mortality, 3.080 (1.050-9.033, p=0.040) in Controls and 0.961 (0.501-1.843) in Cases.
Conclusion: In T2DM, PAOD requiring revascularization affects women at a more advanced age and after a longer diabetes duration: women are thus partly protected from this complication. However, when severe PAOD occurs, it completely effaces the CV protection conferred by female gender also in T2DM and predicts CV events, CV and total mortality with a comparable strength in the two genders.

The association between serum osteoprotegerin levels with lower extremity arterial calcification in patients with type 2 diabetes mellitus
I. Eleftheriadou[1], P. Grigoropoulou[1], V. Argiana[1], I. Balla[1], A. Kokkinos[1], D. Perrea[2], N. Katsilambros[1], N. Tentolouris[1];
[1]First Department of Propaedeutic and Internal Medicine, Laiko General Hospital, [2]Laboratory of Experimental Surgery and Surgical Research, Athens University Medical School, Greece.

Background and aims: Increased OPG levels have been found in diabetic patients with micro- and macrovascular complications. Recent studies have shown that serum osteoprotegerin (OPG) concentrations correlate with coronary artery calcification in patients with type 2 diabetes mellitus (T2DM). Lower extremity arterial calcification (LEAC) is common diabetes. However, no data exists on the association between serum OPG concentrations with LEAC in patients with T2DM. The aim of this study was to look for potential association between serum OPG levels and LEAC in patients with T2DM.
Materials and methods: A total of 74 patients (148 feet) with T2DM were recruited (mean age 67.8±9.0 years, duration of diabetes 15.3±10.9 years). In all patients radiographs were taken of both feet and ankles. LEAC was graded in a scale from 0-5 at 4 locations (posterior tibial and dorsalis pedis arteries bilaterally) as 0: absent; 1: barely visible; 2: slightly visible; 3: specific outline; 4: very dense equal to or lower than 2 cm; 5: very dense greater than 2 cm. The total LEAC score (0-20) at all 4 locations was calculated. Serum OPG levels were measured using ELISA. Diagnosis of peripheral arterial disease (PAD) was based on the presence of either biphasic, monophasic or blunted waveforms at the posterior tibial artery, while diagnosis of PN on neuropathy symptom score (NSS), neuropathy disability score (NDS) and vibration perception threshold (VPT).
Results: Patients with PAD (n=36) had significantly higher serum OPG levels in comparison with those without PAD (18.9±5.9 vs 14.2±3.9 pmol/l, p<0.001). Patients with PN (n=34) had also higher OPG levels than patients without PN (17.8±6.2 vs 14.9±4.0 pmol/l, p=0.021). Patients without or with less LEAC (grade 0-2 based on the maximum LEAC grade at one out of 4 locations; n=44) had lower OPG levels compared with patients with more severe LEAC (grade 3-5; n=30) (14.99±4.4 vs 18.61±6.0 pmol/l, p<0.001). The total LEAC score was significantly associated with age (r=0.23, p=0.011), pulse pressure (r=0.41, p<0.001), glomerular filtration rate (r= -0.20, p= 0.026), albumin-to-creatinine ratio (r=0.36, p<0.001), VPT (r=0.26, p=0.002), serum OPG levels (r= 0.25, p=0.004) and there was a trend for association with diabetes duration (r=0.17, p=0.055). The association between the total LEAC score and OPG concentrations remained significant after adjustment for age (p=0.035), GFR (p=0.021), diabetes duration (p=0.009) and PN status (p=0.003).
Conclusion: Serum OPG levels are increased in diabetic patients with PAD and are associated with severity of LEAC.

1273

Urinary D-lactate levels are increased in type 2 diabetic patients and are inversely associated with ankle arm index: The CODAM study

N.M.J. Hanssen[1], J. Scheijen[1], M.S. Huijberts[1], I. Ferreira[2], M.M.J. van Greevenbroek[1], C.J.H. van der Kallen[1], E.E. Blaak[3], E.J.M. Feskens[4], C.D.A. Stehouwer[1], C.G. Schalkwijk[1];
[1]Internal medicine, Cardiovascular Research Institute Maastricht (CARIM), Maastricht University Medical Centre (MUMC), [2]Internal medicine/ Clinical Epidemiology and Medical Technology Assessment, Cardiovascular Research Institute Maastricht (CARIM), Maastricht University Medical Centre (MUMC), [3]Human biology, Maastricht University, [4]Division of human nutrition, Wageningen University, Netherlands.

Background and aims: Diabetes is associated with increased incidence of peripheral arterial disease (PAD) and its complications (ulcers, cardiovascular mortality). Intracellular glycosylation is increased in diabetes and is linked to vascular complications and may thus be involved in the increased risk for PAD in diabetes. Methylglyoxal is the key precursor for intracellular glycosylations. The glyoxalase pathway catalyzes the conversion of methylglyoxal to D-lactate. The aim of the present study was to investigate, first, whether urinary D-lactate, possibly a reflection of methylglyoxal, is increased in type 2 diabetes; second, whether D-lactate levels are associated with the presence of PAD; and third, whether this association is explained by intracellular hyperglycaemia.
Materials and methods: We investigated 510 (192 women, mean age: 59.5±7.0) participants of the Cohort on Diabetes and Atherosclerosis (CODAM) study with normal glucose metabolism (NGM; n=269), impaired glucose metabolism (IGM; n=114) and type 2 diabetes (DM2; n=127). Urinary D-lactate levels were measured with UPLC-MSMS and corrected for urine creatinine levels. Severity of PAD was determined by the ankle arm index (AAIx). We used linear regression analyses to investigate the association between D-lactate and AAIx, first with adjustments for sex, age and smoking and then for other risk factors (i.e. HDL, triglycerides, eGFR, mean arterial pressure and body mass index). We next determined whether the association could be explained by intracellular hyperglycaemia by further adjustment for HbA1c.
Results: We developed a new method for the detection of D-lactate with UPLC-MSMS with intra- and interassay coefficients of variation of 2.6% (n=10) and 5.6% (n=10) respectively. Median and interquartile range of D-lactate levels were 0.65 (0.34-1.39), 0.78 (0.37-1.51) and 1.39 (0.55-3.89) µmol/mmol creatinine for NGM, IGM and DM respectively (p for trend <0.001). AAIx *decreased* by 0.016 (95%CI: -0.027 to -0.005, p=0.005) per each standard deviation increase in D-lactate in analyses adjusted for age, sex and smoking, and by 0.014 (-0.020 to -0.003), p=0.013 after adjustments for other risk factors. After additional adjustment for HbA1c, this association was attenuated by 40%: to -0.010 (-0.022 to 0.001), p=0.077.
Conclusion: We found that higher urinary D-lactate, as a marker of intracellular methylglyoxal levels, is associated with PAD (as reflected by lower AAIx) in the CODAM study. This association was independent of potential confounders and other risk factors but could at least partially (40%) be explained by HbA1c, a marker for intracellular hyperglycaemia. Our results suggest that intracellular glycation may play an important role in the development of PAD.

1274

Evaluation and comparison of stroke neurological scales regarding long-term outcome of ischaemic stroke in diabetic patients

V. Dragoumanos[1], D. Athanasopoulos[1], A. Koutsovasilis[1], G. Konstantinou[1], S. Tsiaglis[2], D. Vrana[2], A. Melidonis[1];
[1]Diabetes Center, [2]1st Internal Medicine Clinic, Tzaneio General Hospital, Piraeus, Greece.

Background and aims: Neurological impairment scales are frequently used to determine the neurological status of patients suffered ischemic stroke (IS). Stroke scales owe to be able to describe in detail the severity of neurological deficits and predict functional outcomes. The most common neurological impairment scales are: the National Institutes of Health Stroke Scale (NIHSS), the Orpington Prognostic Scale (OPS) and the Scandinavian Stroke Scale (SSS). The purpose of the present study is to evaluate and compare of NIHSS, OSS and SSS to the end points of (IS) - explicitly new stroke or death - in diabetic patients.
Materials and methods: We studied 212 diabetic patients [80(37.7%) men and 132(62.3%) women], 74.9±6 (SD) years old suffered IS. Acute stroke was defined according to World Health Organization criteria. The diagnosis of ischemic stroke was established by neurological examination and confirmed by computed tomography. Baseline neurological examination developed accordingly to NIHSS, OPS and SSS at admission to the hospital. End point was considered new incidence of stroke or death during one year. Evaluation of the linear relationship between NIHSS, OPS and SSS was calculated using Spearman's rank correlation coefficient. Logistic regression analysis models were conducted to investigate how accurate the neurological scales predict end points. The goodness of fit of the models was tested by Hosmer and Lemeshow Test and by Omnibus Test. Statistically significant values were considered for p<0.05.
Results: After 12 months 48(22.6%) diabetic patients [8(3.8%) men and 40(18.9%) women] have had new stroke or died. Analysis using Spearman's rank correlation coefficient indicates a statistically significant linear relationship between NIHSS and OPS (r=0.93, p<0.001). For these data mean±(SD) for NIHSS is 14.85±8.82 and for OPS 3.62±1.22. There was also significant correlation between NIHSS and SSS using Spearman's rank correlation coefficient (r=-0.88, p<0.001). For these data mean±(SD) for NIHSS is 14.85±8.82 and for SSS 35.26±12.2. OPS and SSS were also strongly correlated (r=-0.85, p<0.001). For these data mean±(SD) for OPS is 3.62±1.22 and for SSS 35.26±12.2. At logistic regression model baseline NHISS (RR=0.69 95% CI: 0.56-0.85, p=0.001) and SSS (RR=0.780 95% CI: 0.69-0.87, p<0.001) were significant predictors of new stroke or death, but OPS (RR=4.08 95% CI: 0.92-18.06, p=0.064) was not related to the end-points of IS in one year. For every one point increase in NIHSS, the relative risk of new stroke or death in diabetic patients increased by a factor of 0.69, while for every one point decrease in SSS, such risk increased by a factor of 0.78.
Conclusion: Neurological stroke scales can be used to predict likelihood of outcome in diabetic patients that suffered IS. NHISS, OPS and SSS are strongly correlated and a lot of the standardized assessments of each scale are comparable to each other. Baseline NIHSS and SSS are significant predictors of new stroke or death in diabetic patients in one year. SSS has a slightly higher prognostic capacity compared with NIHSS in diabetic patients. Further studies in larger population may reveal more interesting conclusions.

1275

Impact of different glycaemic indices during hospitalisation on long-term outcome of diabetic patients after an ischaemic stroke

D. Athanasopoulos[1], V. Dragoumanos[1], A. Koutsovasilis[1], G. Giannikopoulos[1], E. Loizos[2], D. Vrana[2], A. Melidonis[1];
[1]Diabetes Center, [2]1st Internal Medicine Clinic, Tzaneio General Hospital, Piraeus, Greece.

Background and aims: Diabetes is well recognized as a major risk factor for the development of stroke. It doubles the risk of ischemic stroke (IS) and worsens survival of patients with acute stroke. Hyperglycemia is prevalent in the early phase of acute ischemic stroke and is associated with worse neurological outcome and increased stroke mortality. The purpose of the present study is to assess the significance of a selection of admission and during hospitalization glycemic indices in the prediction of neurological outcome among diabetic patients that suffered IS.
Materials and methods: We studied 212 diabetic patients [80(37.7%) men 132(62.3%) women], 74.9±6 (SD) years old suffered IS for one year period time. Acute stroke was defined according to World Health Organization criteria. The diagnosis of ischemic stroke was established by neurological examination and confirmed by computed tomography. Neurological examination was developed according to the National Institute of Health Stroke Scale (NIHSS). Improvement of neurological outcome was considered a modification of equal or less than 4 points in NIHSS. Adjusted and unadjusted logistic regression analyses was conducted to investigate how accurate improvement in neurological outcome can be predicted by admission plasma glucose concentration (APG), fasting plasma glucose concentration (FPG), postprandial plasma glucose concentration (PPG), glucose spikes (GS), glycosylated hemoglobin (HbA1c) and diabetes duration in years for discharge, 3 months, 6 months and 12 months period time.
Results: At discharge neurological improvement observed on 32(15,1%) men and 44(20.8%) women [total 76(35.8%)], at 3 months 48(22.6%) men and 56(26.4%) women [total 104(49.1%)], at 6 months 72(34%) men and 76(35.8%) women [total 148(69.8%)] and at 12 months 72(34%) men

and 80(37.7%) women [total 152(71.7%)]. At discharge diabetes duration (OR=0.93 95% CI: 0.89-0.98, p=0.005) was significant predictor of outcome but APG, FPG, PPG, GS and HbA1c were not significant to functional outcome. At 3 months significant prediction of outcome was made by diabetes duration (OR=0.91 95% CI: 0.86-0.96, p=0.001) and HbA1c (OR =2.72, 95% CI: 1.27-5.83, p=0.01). At 6th month significant predictors of aggravation were diabetes duration (OR=1.08 95% CI: 1.01-1.15, p=0.012) and APG (OR=1.01 95%CI: 1.00-1.03, p=0.039). At 12th month APG (OR=1.01 95% CI: 1.00-1.03, p=0.018) and HbA1c (OR=1.76 95% CI: 1.06-2.91, p=0.027) predicted significantly the outcome.
Conclusion: Hyperglycemia worsens the neurological outcome of IS in diabetic patients. Each glycemic index corresponds to a significant predicting factor in different time period. Diabetes duration in addition to its recent prior regulation as expressed by HbA1c contribute critically to prognosis of IS in diabetic patients. Long diabetes duration predicts negative outcome of IS at discharge, 3rd and 6th month. HbA1c is a significant predictor of neurological outcome at 3 and 12 months. APG appears to have an important effect on the prognosis of IS at 6th and 12th month.

PS 127 Complications in type 1 diabetes

1276

Macrovascular complications may be associated with tighter glycaemic control in patients with type 1 diabetes: An analysis of primary care data in the UK

E.J. Edson[1], T.K. Le[1], D.R. Nelson[1], D. Haldane[1], A.B. Mendelsohn[2], S. Pillemer[2], B.H. Curtis[1];
[1]Global Health Outcomes, Eli Lilly and Company, Indianapolis, [2]Clinical Research, Macrogenics, Inc., Rockville, USA.

Background and aims: The Diabetes Control and Complications Trial (DCCT) and follow-on Epidemiology of Diabetes Interventions and Complications Study (EDIC) conducted in the US and Canada demonstrated beneficial effects of tight glycemic control on the micro- and macrovascular complications of type 1 diabetes mellitus (T1DM) in a randomised controlled clinical trial setting. However, the outcomes of intensive glycemic control in clinical practice are not known. We conducted the present study to 1) identify and describe a cohort of patients with T1DM from the General Practice Research Database (GPRD) and 2) compare cumulative rates of micro- and macrovascular complications, based on the degree of HbA1c control achieved within 10 years of diagnosis.
Materials and methods: Data were derived from GPRD that collects data from medical practices within the UK. Logistic regression was used to create pairwise propensity scores between three groups of patients: tightly controlled (TC=HbA1c ≤6.5%); reasonably controlled (RC= HbA1c >6.5 and ≤7.5%); poorly controlled (PC=HbA1c >7.5%). Analyses of clinical endpoints utilized logistic regression with independent variables of propensity score quintiles, pairwise comparison of the HbA1c control group, and interaction of those two. Adjusted event rates were based on logistic regression models with all three groups included. Endpoints included microvascular complications (e.g. diabetic retinopathy, nephropathy) and macrovascular/cardiovascular (CV) events (e.g. myocardial infarction, ischemic heart disease, stroke). Endpoints were determined by diagnosis codes within the GPRD.
Results: The average age of study patients (N= 1086) at baseline was 25.8 (SD: 16.0) years; 60% male. Microvascular complications did not differ significantly between groups, although numerically the RC group demonstrated lower adjusted rates when compared to both the TC and PC groups (Table 1). There were no significant differences in macrovascular/CV events between either TC or PC patients when compared to RC, however a significant difference was noted after propensity score adjustment in the TC group compared to the PC group (OR=3.13; 95% CI, 1.39-7.14; p=0.006).
Conclusion: Using data from routine medical practice, we found, in contrast with the DCCT/EDIC results, no significant microvascular or CV benefit in T1DM patients treated intensively to control blood glucose versus those treated conventionally. Additionally, we observed increased macrovascular/CV events in TC versus PC patients. In light of results from recent high profile trials in type 2 diabetes mellitus which suggest increased mortality related to intensive glycemic control and its inherent risk of hypoglycemia, additional investigation of this association is warranted in T1DM patients.

Table 1: Microvascular Complications and Macrovascular/CV Events by Glycemic Control Groups

	Microvascular Complications			Macrovascular/CV Events		
	TC vs. RC	PC vs. RC	TC vs. PC	TC vs. RC	PC vs. RC	TC vs. PC
Odds Ratio	2.0	1.72	1.05	2.08	0.58	3.13
(95% CIs)	(0.75-5.26)	(0.97-3.07)	(0.53-2.13)	(0.79-5.56)	(0.29-0.13)	(1.39-7.14)
p-value	p=0.17	p=0.07	p=0.88	p=0.14	p=0.11	p=0.006
Adjusted Rates	16.9% / 9.6%	16.4% / 9.6%	16.9% / 16.4%	6.1% / 2.4%	2.7% / 2.4%	6.1% / 2.7%

Tei Index identifies the early phase of left ventricular dysfunction in young patients with long-lasting type 1 diabetes mellitus and preserved systolic function

K. Kurnicka, B. Lichodziejewska, D. Liszewska-Pfejfer, A. Lipinska, M. Ciurzynski, K. Grudzka, P. Pruszczyk;
Internal Medicine and Cardiology, Medical University of Warsaw, Poland.

Background and aims: The Tei Index (TI) is an easily obtained and reproducible Doppler parameter which reflects combined left ventricular (LV) systolic and diastolic function. Increased values of TI were found in patients with dilated cardiomyopathy and myocardial infarction and were proved to be an independent prognostic factor for higher mortality. The clinical usefulness of TI for young patients with type 1 diabetes mellitus (DM1) has not yet been fully studied. The aim of our study was an echocardiographic assessment of LV global function in patients with long-lasting DM 1, below 45 years of age, treated with intensive insulin therapy.
Materials and methods: The study group (DM): 100 pts (51F, 49M), mean age 30,0 yrs, with mean diabetes duration 15,7yrs, without drugs except insulin (mean 44 units/24h), with mean HbA1c 9,4%, without hypertension and overt heart disease, with good LV ejection fraction (>60%). The control group (C): 60 healthy persons (29F, 31M) in similar age. Mitral valve flow (MVF) and aortic valve flow spectra were registrated using pulse-wave Doppler. The TI, which is a ratio of the sum of isovolumetric contraction time and isovolumetric relaxation time (IVRT) to LV ejection time was calculated.
Results: There were no differences in mean values of heart rate, systolic and diastolic blood pressure, Body Mass Index, Body Surface Area, LV mass and LV mass index, lipids parameters and percentage of cigarette smokers between groups. In MVF assessment the mean E/A value (the ratio of early to atrial maximal velocity) was significantly lower in DM than in C group (1.33±0.3 vs 1.44±0.3, p=0.03), but it remained within the normal range for this age group. Mean TI value was especially significantly higher in DM than in C group (0.48±0.09 vs 0.38±0.05, p<0.001). In 51 pts of DM group TI exceeded the value of 0.49, the upper normal limit (mean value = 0.55 ± 0.05). All persons in C group had normal TI, with maximal value 0.46. The TI elevation is probably dependent on LV prolonged relaxation, due to the mean IVRT value was significantly higher in DM than in C group (60.1±8.0 vs 57.6±6.2 ms, p=0.03). There were no significant differences between the TI values related to duration and the level of metabolic control of DM1, number and type of complications, as well as between subgroups of women and men or younger and older patients. Correlation and multivariate analyses did not identify any important factor which might exert a significant effect on increased TI values in young diabetics.
Conclusion: Significantly higher Tei Index values observed in young patients with long-lasting type 1 diabetes mellitus with preserved LV systolic function may identify subjects with preclinical impairment of LV diastolic function. The significance of this phenomenon requires further investigation.

1278

Family history of hypertension or diabetes predicts IMT in well-controlled patients with type 1 diabetes

A. Hiukka[1], E. Häppölä[2,3], M.-R. Taskinen[1], P.-H. Groop[2,3], S. Mäkimattila[3];
[1]Department of Medicine, Helsinki University Central Hospital and Biomedicum, [2]Department of Medicine, Helsinki University Central Hospital, [3]Folkhälsan Institute of Genetics, Folkhälsan Research Center and Biomedicum, Helsinki, Finland.

Background and aims: In middle-aged subjects with type 1 diabetes, mortality due to ischemic heart disease is increased four- to seven-fold. Carotid intima-media thickness (IMT) is used as a surrogate marker of preclinical atherosclerosis. We searched for predictors of IMT in adults with type 1 diabetes in a prospective setting.
Materials and methods: A total of 57 patients (F/M = 27/30) were followed after their diagnosis until they reached 41±4 years of age, when duration of diabetes averaged 31±3 years. Cardiovascular risk markers [lipids, blood pressure, smoking, urinary albumin excretion rate (AER), alcohol consumption, family history] were evaluated at the 10 year, 20 year, and 30 year visits. During follow-up, IMT of the carotid arteries was determined.
Results: The patients were reasonably well-controlled with HbA1C of 7.7±0.9%, blood pressure of 133±16/78±9mmHg and LDL-Chol of 2.8±0.9mmol/L. Altogether 30 patients had positive family history of hypertension and/or diabetes (FHD+). These patients and those with FHD- did not differ concerning smoking, glycemia, lipids, AER, or BMI at any study visit. FHD+ patients had higher systolic blood pressure at the 20 year visit (129 ±16 vs. 117±11, p=0.042), despite having more antihypertensive medications. At any visit, other blood pressure values did not differ. At the 30 year visit, measures of IMT were significantly higher in FHD+ patients (eg. maximum IMT 1.03±0.12mm vs. 0.95±0.09mm, p=0.005) and their carotid plaque score was two-times higher compared to the FHD- group (p=0.005). Of the single measures from the 10 year visit, BMI showed the best correlation to the 30-year IMT (r=0.437, p<0.001).
Conclusion: Patients with type 1 diabetes and a positive family history of diabetes or hypertension have higher carotid IMT than patients without such a history. Even if well-controlled regarding risk factors, these patients are exposed to high cardiovascular risk.

Association of risk factors and glycaemic control with endothelium-dependent vascular dysfunction in type 1 diabetes

A.S.M. da Costa[1], E. Tibiriçá[1,2], P.B. da Silva[1], M.B. da Matta[1], M.B. Gomes[1];
[1]Diabetes Unit, State University of Rio de Janeiro (UERJ), [2]Laboratory of Neuro-Cardiovascular Pharmacology, Oswaldo Cruz Institute, Fiocruz, Rio de Janeiro, Brazil.

Background and aims: Endothelial dysfunction in patients with type 1 diabetes (T1DM) is an early event in the pathogenesis of vascular complications. However, little is known about the potential risk factors associated with impairment of the vascular reactivity in this population. The purpose of this study was to assess endothelial function in the microcirculation, correlating with possible factors involved such as glycemic control and potential markers of cardiovascular risk (uric acid and C reative protein- CRP) , and compare the results with those of healthy controls.
Materials and methods: A cross-sectional study was conducted in 57 T1DM patients , aged 32.5 (13-61) years and with a 15 (1-48) years disease duration, and 53 age-, sex-, and weight- matched controls. The median Hba1c was 9,3 (5,4-12,1).Skin perfusion was measured at the forearm using laser Doppler flowmetry during low-current iontophoresis of acethylcoline (ACh) (endothelium dependent response)and sodium nitroprusside(SNP)(Endothelium-independent response) . Post occlusive reactive hyperemia (PORH) and maximum vasodilator function during thermal hyperemia were also assessed. Diabetic patients underwent clinical and laboratory evaluation (disease duration, daily insulin dose, blood pressure, body mass index, urinary albumin excretion, lipid profile, glycemic control , uric acid and CRP).
Results: Microvascular response to ACh was significantly reduced in patients (p=0,002). However, despite the reduction of area under curve (AUC) of NPS, the analysis with repeated measures disclosed no difference between the groups in relation to the doses(p=0,15). Maximal skin microvascular vasodilation induced by thermal hyperemia was found to be higher in the control group than among patients {93,6 PU(perfusion units) (24,5-379-,9) and 56,6 PU (31,5-204,5)}, respectively p=0,004). On the other hand, during PORH, maximal increase in flux and AUC of hyperemic response did not differ between patients and controls, although the time frame to reach maximum flux and the time to half recovery after hyperemia was longer in patients than in controls (P=0.02). Endothelium-dependent response was correlated to diabetes duration (r= -0,33 p=0,01), tryglicerides (r= -0,37 p=0,005), insulin dose (r= -0,28 p=0,03), fasting glycemia (r= -0,3 p=0,02), hba1c (r= -0,34 p=0,001) and uric acid (r= -0,3 p=0,005), as well as independent-endothelium responses were correlated to capilar glycemia(r=0,30 p=0,02) and CRP (r=0,29 p=0,02). Uric acid levels were higher in non-diabetic than in diabetic subjects (4,40± 1,48 x 3,6 ± 1,0, respectively p=0,03), and were unrelated to endothelium-dependent response(r=0,08 p=0,55). In diabetics, on stepwise multivariate analysis, age, hba1c and uric acid were the most important factors associated with the AUC of ACh (p=0,02), and CRP with AUC of NPS (p=0,04).
Conclusion: We conclude that in T1DM patients the endothelium-dependent vascular response and maximal vasodilator capacity are significantly reduced and normal serum urate, glycemic control, age and CRP were the most important contributing factors to the variation of microvascular reactivity. And the inverse association of uric acid levels and ACh response can be explained probably by the loss of the antioxidant properties of urate.

Impaired 24-hour blood pressure variation in adolescents and adult normoalbuminuric type 1 diabetes patients

L.J. Machnica[1], G. Deja[1], P. Jarosz-Chobot[1], L. Czupryniak[2], M. Pawlowski[2], E. Szymanska-Garbacz[2], M. Saryusz-Wolska[2], J. Loba[2];
[1]Pediatrics, Endocrinology and Diabetes, Medical University of Silesia, Katowice, [2]Internal Medicine and Diabetology Department, Medical University of Lodz, Poland.

Background and aims: The absence of >=10% blood pressure (BP) drop at night ("non-dipping" phenomenon) is being recognized as a significant risk factor of vascular complications of diabetes. Little is known on the role of vascular factors like endothelium function and subclinical inflammation in the development of disturbed 24-hour blood pressure rhythm in type 1 diabetes (T1DM). The aim of the study was to assess blood pressure rhythm in adolescent and adult subjects with type 1 diabetes.
Materials and methods: The study comprised two groups of normoalbuminuric T1DM patients: Group A - 52 adolescents (mean age 14.1±3.0 yrs, diabetes duration 5.1±2.2 yrs, HbA1c 7.2±1.0%) with; Group B - 62 adults (mean age 34.1±7.2 yrs, diabetes duration 4.8±2.5 yrs, HbA1c 7.2±1.1%) and a group of healthy controls (Group C; mean age 23.1±4.4 yrs). All subjects had 24-hour blood pressure monitoring performed with the use of SpaceLabs 90207. Fasting plasma adhesion molecules sVCAM and sICAM, sE-selectin, adiponectin, interleukin IL-6, and TNF-alfa concentration were measured.
Results: 25 (48%) subjects from Group A and 9 (15%) from Group B were "non-dippers"; no "non-dippers" were found in Group C. There were no statistically significant differences in vascular and inflammatory parameters between "dippers" and "non-dippers" from Group A and Group B or the controls (table). However, mean 24-hour systolic (SBP) and diastolic blood pressure (DBP) was significantly lower in Group A than in Group B and C: 118±10 and 66±5; 126±11 and 73±6, and 128±12 and 73±6 mmHg ($p<0.01$). In particular, SBP at night was significantly lower in "non-dippers" than in "dippers" from Group A: 105±8 and 113±10 mmHg ($p<0.01$), while DBP was similar: 57±3 and 60±7 mmHg, respectively. There was a significant positive correlation between 24-hour SBP and body mass index (BMI) in Group A and B subjects ($r=0.41$ and $r=0.32$, respectively).
Conclusion: In adolescent or adult patients with T1DM non-dipping phenomenon is not associated with endothelial dysfunction or increased subclinical inflammation. In addition, unusually high prevalence of non-dipping in adolescent subjects with T1DM suggests that establishing this diagnosis with traditional criteria might not be at all appropriate in this population. Children and adolescents with T1DM display lower BP than the older persons, therefore they physiologically might not be subject to >=10% decrease of BP at night. For the assessment of diurnal blood pressure variation in adolescent T1DM patients different criteria of BP nighttime reduction might be necessary to apply.

Co-morbidity and survival of patients with type 1 diabetes on renal replacement therapy

J. Helve[1], M. Haapio[2], C. Grönhagen-Riska[3], P. Finne[4];
[1]Department of Medicine, Lappi Central Hospital, Rovaniemi, Finland, [2]Division of Nephrology, Helsinki University Central Hospital, Helsinki, [3]Department of Medicine, Helsinki University Central Hospital, [4]Finnish Registry for Kidney Diseases, Helsinki, Finland.

Background and aims: Mortality among patients with type 1 diabetes on renal replacement therapy is high. The effect of co-morbidities on their survival has not been previously estimated. The aim of this study was to estimate effect of co-morbidities on survival of type 1 diabetes patients on renal replacement therapy.
Materials and methods: An incident cohort of all type 1 diabetes patients entering chronic renal replacement therapy (n=656) in Finland between 2000 and 2008 was followed until death or the end of follow-up on 31 December 2008. All data were obtained from the Finnish Registry for Kidney Diseases, which collects information on co-morbidities at the start of renal replacement therapy. The main outcome was crude and adjusted relative risk of death according to co-morbidities.
Results: At start of renal replacement therapy 22% of the type 1 diabetic patients had coronary artery disease, 18% had peripheral vascular disease, 10% had cerebrovascular disease, 33% had left ventricular hypertrophy, and 7% had heart failure. All observed co-morbidities were significant predictors of death when analyzed univariably (RR 1.56-4.87). The 5-year survival probability of patients without (reported) co-morbidities was 74%, while it was 56% and 37%, respectively, for those with one or more than one co-morbidities. When the co-morbidities were studied in a multivariate model, also adjusting for age and gender, peripheral vascular disease (RR 1.88), left ventricular hypertrophy (RR 1.68) and heart failure (RR 2.50) remained independent risk factors of death.
Conclusion: Co-morbidities are common among type 1 diabetes patients entering renal replacement therapy, and they are strong predictors of death. Therefore, it is essential to diagnose and adequately treat co-morbidities.

Increased oxidative damage to de novo synthesized ApoA-1 in untreated type 1 diabetic patients - a novel method to identify the relative age of proteins

A. Jaleel, G. Henderson, B. Madden, K. Klaus, D. Morse, S. Gopala, K. Nair;
Endocrinology, Mayo Clinic & Foundation, Rochester, USA.

Background and aims: Oxidative damage and other post-translational modifications (PTM) in proteins, and accumulation of these proteins, may cause complications in diabetes. In order to address this issue, we developed a novel methodology to identify relative age of protein isoforms and to assess post-translational modifications by studying Apolipoprotein A-1.
Materials and methods: This method involves in vivo stable isotope labeling of proteins, protein isoform purification by two dimensional gel electrophoresis (2DGE), and isotopic enrichment (IE) and PTM analysis by tandem mass spectrometry. To label newly synthesized proteins, [ring-$^{13}C_6$]phenylalanine was intravenously infused for 8 hours in type 1 diabetic (T1D) participants with (I+) and without (I-) insulin treatment and non-diabetic (ND) participants (plasma glucose mmol/L; T1D I- = 17.0 ± 0.6, T1D I+ = 5.2 ± 0.2, ND = 4.9 ± 0.1).
Results: Only protein isoforms synthesized during infusion would incorporate the isotope label. In 2DGE and we identified 5 isoforms of ApoA-1. Pro-ApoA-1 (gel spot E) contained higher IE (ratio of [ring-$^{13}C_6$]phenylalanine to total phenylalanine), while older forms with higher degrees of damage (oxidation, deamidation) displayed less IE. Insulin deprivation in T1D increased the amount of oxidation in ApoA-1 ($P<0.05$) with more rapid maturation and damage of *de novo* synthesized pro-ApoA-1 ($P<0.05$) (% ^{13}C-labeling of mature ApoA-1 vs pro-ApoA-1: T1D I-= 13 ± 3, T1D I+ = 6 ± 1, ND = 5 ± 1).
Conclusion: The results show that ApoA-1, important for lipoprotein metabolism, is oxidatively damaged soon after synthesis during insulin deficiency that likely contributes to the cardiovascular complications during insulin deficiency and poor glycemic control in T1D.

Figure. A) The ratio of isotopic enrichment in older versus newer (C/E) ApoA-1 spot C demonstrates that the ratio is higher (P<0.05) in T1D during insulin deprivation indicating that newly synthesized ApoA-1 rapidly shifted to older form. B) Carbonylation (oxidation) in gel spot C of ApoA-1 is higher (P<0.05) in T1D during insulin deprivation.

The adverse effects of diabetic ketosis on the heart in young and middle-aged patients

Z. Qiumei;
Tianjin Medical University Metabolic Disease Hospital, China.

Background and aims: To observe the changes of myocardial enzymogram and electrocardiogram confirmed the myocardial damage during diabetic ketosis (DK)or diabetic ketoacidosis(DKA) in middle-aged patients.
Materials and methods: 78 hospitalized patients (45 male and 33 female) with DKA were recruited. Standard of Admission: Under 45 years old ; Above urine acetone bodies 2+; Without evidence of overt ischaemic heart disease; Without obvious infection and chronic disease history.Myocardial enzymogram which included creatine phosphokinase (CK), creatine phosphokinase isoenzyme(CK-MB) and aspart aminotransferases(AST) were measured on admission at ketosis stage and at 7 days after ketosis recovery. Electrocardiographs were also performed and compared during two stages.
Results: 78 hospitalized patients with DK or DKA had significantly higher levels of myocardial enzymogramCK,CK-MB and AST at ketosis stage compared to at stable stage. The changes of ECG were found in 46 cases (58.9%)of all the patients. The highest morbidity of ECG abnormality was ST-T change which was found in 32 cases(41.0%),ST segment depression in 8 cases, ST segment height in 1 case,T wave flat or inversion in 24 cases, sinus tachycardia in 18 cases (23.1%). 32 cases out of abnormal ECG in 46 cases improved at 7 day after ketosis recovery; in 20 cases recovered to normal. The levels of CK,CK-MB and AST with abnormal ECG at acute stage were significantly higher than those with normal ECG.. 3 patients with severe ketoacidosis in 78 cases, minute elevations of myocardial biomarkers 2 folds above reference value , ST segment depression 0.1mV in 2 cases and ST segment height in 1 case compatible with myocardial infarction. The higher levels of CK,CK-MBand AST restored to normal and change of ECG overtly improved at the stable stage, ST segment raised up 0.05 mV in 2 patient those ST segment depression,ST segment height in 1 case restored to normal also.
Conclusion: Diabetic ketoacidosis, particularly when severe, has a nonspecific myocardial injury, the level of myocardial enzymogram caused by diabetic ketosis could be abnormally higher. We should monitor the heart change and take an effective protective action during ketosis episode, the patients should be followed up and evaluated after recovery.

1284

Genetic variability of histone methyltransferases and the risk of diabetic complications in patients with type 1 diabetes

A. Tiitu[1], A. El-Osta[2], C. Forsblom[1,3], L. Tarnow[4], H.-H. Parving[5], M.E. Cooper[2], P.-H. Groop[1,3];
[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland, [2]Epigenetics in Human Health and Disease, Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [3]Div Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland, [4]Steno Diabetes Center, Gentofte, Denmark, [5]Department of Medical Endocrinology, University Hospital, Copenhagen, Denmark.

Background and aims: There appears to be a complex interplay between genes and lifetime glucose exposure, which increases the risk of diabetic complications in patients with type 1 diabetes (T1D). However, the underlying molecular mechanism responsible for this phenomenon remains unexplained. We have demonstrated that exposure to glucose may lead to alterations of the methylation patterns of DNA and histones of essential genes, an epigenetic phenomenon that is increasingly considered to maintain the hyperglycaemic memory of critical cells. Since it has recently been shown that altered histone methylation is associated with an inflammatory phenotype in white blood cells and vascular cells when exposed to diabetic conditions, we hypothesized that genes coding for the enzymes that methylate histones, the histone methyltransferases SuV39 and SetD7, play a role in the development of diabetic complications.
Materials and methods: The first dataset included 2991 patients with T1D from the FinnDiane study. 811 patients had diabetic nephropathy (DN) defined as macroalbuminuria or ESRD, and 1070 patients had normal AER despite being exposed to diabetes for at least 15 years. 1168 patients were laser treated for retinopathy. The replication dataset included 888 patients from the Steno Diabetes Center, 452 were diagnosed with DN and 432 had normal AER. 416 patients had proliferative retinopathy. Genetic data on the CEPH population in the HapMap database (phase II) was used to select tagSNPs covering all SNPs in the genes *SuV39h1, SuV39h2* and *SetD7*. A total of 37 SNPs were selected for genotyping with the Sequenom MassARRAY iPLEX system or the TaqMan chemistry. P-values are presented both for raw data (p) and corrected for multiple testing (p_{corr}). Classical risk factors included in the logistic regression models are duration of T1D, systolic blood pressure, triglycerides, HbA_{1c}, male sex, smoking and BMI.
Results: In the FinnDiane, the SNP most strongly associated with DN was rs11100112 (*SetD7*) with minor allele frequencies of 18.0% in cases and 20.7% in controls (p=0.043/p_{corr}=NS). The minor allele of rs11100112 seemed protective after adjustment (OR=0.790[0.638-0.978], p=0.031). The SNP rs12572872 (near *SuV39h2*) showed a genotypic association with laser-treated retinopathy (p=0.0007/p_{corr}=0.030) with minor allele frequencies of 15.6% in cases and 18.7% in controls (p=0.003/p_{corr}=NS). When adjusted for classical risk factors, the minor allele containing genotype was protective (OR=0.814 [0.662-1.000], p=0.05). Six SNPs were chosen for replication but there were no significant associations, although the effects showed the same direction for both SNPs rs11100112 and rs12572872. When both study populations were combined (Fisher's method) no significant results were observed. When patients with HbA_{1c} and duration above/below medians were analyzed separately, no significant results were either recorded.
Conclusion: No clear association of polymorphisms in the specific histone methyltransferase genes examined and diabetic complications could be seen.

PS 128 Hypertension

1285

Initial combination therapy with aliskiren and hydrochlorothiazide is more effective than amlodipine in patients with stage 2 systolic hypertension and diabetes mellitus

R.R. Townsend[1], A. Forker[2], P. Rumpelt[3], C. Cherif Papst[4], A. Yadao[3]; [1]University of Pennsylvania Medical Center, Philadelphia, USA, [2]Saint Luke's Lipid and Diabetes Research Center, Kansas City, USA, [3]Novartis Pharmaceuticals Corporation, East Hanover, USA, [4]Novartis Pharma AG, Basel, Switzerland.

Background and aims: Agents that act on the renin-angiotensin-aldosterone system (RAAS) are considered drugs of choice for the treatment of hypertension in patients with diabetes mellitus. Direct renin inhibitors (DRIs) bind to and inhibit renin, which catalyzes the rate-limiting step of the RAAS. This 8-week, double-blind study compared the blood pressure lowering (BP) efficacy and safety of aliskiren/hydrochlorothiazide (ALI/HCT) combination *vs.* amlodipine (AML) in 860 male and female adults with stage 2 systolic hypertension (mean sitting systolic BP [msSBP] ≥ 160 and < 200 mmHg) and type 2 diabetes mellitus.
Materials and methods: After a 1-4 week washout, eligible patients (mean age: 59.8 years; mean BMI: 34.6 kg/m^2) were randomized to ALI/HCT 150/12.5 mg (n = 428) or AML 5 mg (n = 432). After 1 week, doses were force-titrated to ALI/HCT 300/25 mg or AML 10 mg, and patients were treated for an additional 7 weeks. The primary efficacy variable was change from baseline in msSBP at the Week 8 endpoint. Analysis to assess non-inferiority was performed, followed by superiority testing if ALI/HCT was shown to be non-inferior to AML.
Results: Baseline BPs were similar between the two groups: ALI/HCT: 168.0/91.4 mmHg and AML: 167.4/91.3 mmHg. At Week 8 endpoint, least squares (LS) mean reductions in msSBP were significantly greater with ALI/HCT *vs.* AML (-28.8 mmHg *vs.* -26.2 mmHg, LS mean difference: -2.6 mmHg; p <0.0001 non-inferiority; p = 0.0102 superiority). At study endpoint, a significantly greater percentage of patients receiving ALI/HCT achieved the BP goal of <130/80 mmHg compared with AML (23.2% *vs.* 13.8%; p <0.0001). Both treatments were generally well tolerated. Peripheral edema was more frequent with AML (16.2% *vs.* 2.1%) while dizziness was more frequent with ALI/HCT (3.0% *vs.* 0.9%).
Conclusion: Initial treatment with ALI/HCT 300/25 mg is significantly more effective than AML 10 mg at reducing msSBP and attaining BP control in patients with stage 2 systolic hypertension and type 2 diabetes mellitus.

1286

Aliskiren reduces albuminuria independent of baseline blood pressure in combination with losartan in patients with type 2 diabetes and nephropathy

H.-H. Parving[1,2], F. Persson[3], J.B. Lewis[4], E.J. Lewis[5], N.K. Hollenberg[6]; [1]Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark, [2]Faculty of Health Sciences, Aarhus University, Denmark, [3]Steno Diabetes Center, Gentofte, Denmark, [4]School of Medicine, Vanderbilt University, Nashville, USA, [5]Medical Center, Rush University, Chicago, USA, [6]Brigham and Women's Hospital, Harvard Medical School, Boston, USA.

Background and aims: Elevated blood pressure (BP) is a key contributor to development and progression of proteinuria and nephropathy in patients with type 2 diabetes. Direct renin inhibition with aliskiren (ALI) may offer renoprotective effects beyond BP reduction. This *post hoc* analysis assessed the influence of baseline BP on the antiproteinuric effect of ALI or placebo (PBO) added to losartan (LOS) in the Aliskiren in the EValuation of PrOteinuria In Diabetes (AVOID) study.
Materials and methods: In AVOID, 599 patients aged 18-85 years with hypertension and diabetic nephropathy received 6 months' ALI (150 mg force titrated to 300 mg after 3 months) or PBO added to LOS 100 mg daily and optimal antihypertensive therapy. Key exclusion criteria were non-diabetic kidney disease, eGFR <30 ml/min/1.73 m^2 and serum potassium >5.1 mmol/l. Changes in early morning urinary albumin:creatinine ratio (UACR) and eGFR at week 24 endpoint were assessed by subgroups of baseline BP: Group A, <130/80 mmHg (n = 159); Group B, <140/90 mmHg but >130/80 mmHg (n = 189) and Group C, >140/90 mmHg (n = 251).
Results: Mean baseline BP values (mmHg) for each subgroup were 120/71 (Group A), 133/78 (Group B) and 145/81 (Group C).The demographic, clinical and laboratory data were balanced between the three groups. The antiproteinuric effects of ALI were consistent across BP subgroups (19-22% reduction in UACR vs PBO, p = 0.977 for interaction). In Group C (BP >140/90 mmHg at baseline), the decline in eGFR was significantly lower with ALI than with PBO (p = 0.0096). There were no significant differences in the change in BP from baseline in any subgroup.
Conclusion: This *post hoc* analysis of the AVOID trial suggests that aliskiren 300 mg added to losartan 100 mg plus optimal antihypertensive therapy provides renoprotective effects independent of baseline BP in patients with type 2 diabetes and nephropathy.

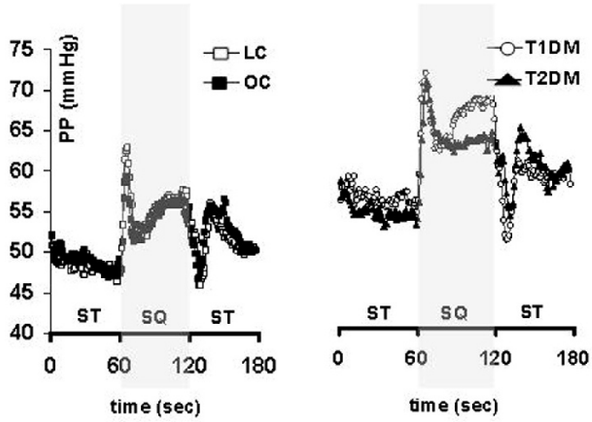
1287

Patients with type 1 or type 2 diabetes have similarly increased pulsatility stress at comparable age of 50 years

A.J.L. Scheen, J.-C. Philips, M. Marchand;
Division of Diabetes, Nutrition and Metabolic Disorders, CHU Sart Tilman, Liège, Belgium.

Background and aims: Arterial pulse pressure (PP) is considered as an independent cardiovascular risk factor in both patients with type 1 (T1DM) and type 2 (T2DM) diabetes mellitus. However, patients with each type of diabetes are exposed to a quite different toxic vascular environment. We compared PP and PP x heart rate (HR) double product (PPxHR = "pulsatile stress") during an active orthostatic test in patients with T1DM and patients with T2DM matched for age (40-60 years).
Materials and methods: 40 patients with T1DM (mean age 50 years, diabetes duration 23 years, body mass index - BMI - 23.0 kg/m^2, HbA1c 8.4%) were compared to 40 patients with T2DM (respectively, 50 years, 8 years, 29.7 kg/m^2, 7.6%). Patients taking antihypertensive agents or with renal insufficiency were excluded. All patients were evaluated with a continuous noninvasive arterial blood pressure monitoring (Finapres®) in standing (1 min), squatting (1 min) and standing position again (1 min). Patients with T1DM or T2DM were compared with two groups of 40 age- and BMI-matched healthy subjects (sex ratio 1/1 in all groups)(Figure).
Results: Despite similar mean arterial pressure (MAP), patients with T1DM and patients with T2DM showed significantly higher PP, HR and PPxHR double product levels than corresponding controls : in T1DM, 59 vs 52 mm Hg for PP (P= 0.016) and 5263 vs 4121 mmHg/min for PPxHR (P=0.0004); in T2DM, 58 vs 52 mm Hg for PP (P= 0.045) and 5359 vs 4321 mmHg/min for PPxHR (P=0.0023). However, there were no significant differences between patients with T1DM and T2DM regarding mean overall values of MAP (126 vs 128 mmHg), PP (59 vs 58 mmHg), HR (89 vs 88/min), and PPxHR product (5263 vs 5359 mmHg/min). During the transition from standing to squatting position, PP increase (+10 vs +8 mmHg) and HR reduction (-6 vs -6 beats/min) were significant but similar in both groups, resulting in a similar modest and non significant rise in PPxHR (+557 vs +449 mmHg/min).
Conclusion: Patients with T1DM have similarly increased PP, an indirect marker of arterial stiffness, and PPxHR double product, an index of pulsatile stress, as non-hypertensive patients with T2DM at similar mean age of 50 years. We hypothesize that such comparable pulsatile stress despite quite different natural history of the diabetic disease may be explained by a much longer exposure to chronic hyperglycaemia in patients with T1DM, on the one hand, and by the presence of associated risk factors such as obesity and insulin resistance in patients with T2DM, on the other hand.



PP changes during an orthostatic test :
standing (ST) - squatting (SQ : grey zone) - standing (ST)
Left : overweight controls (OC) versus lean controls (LC)
Right : patients with T1DM versus patients with T2DM

Pulse pressure and systolic non-dipping, but not ambulatory arterial stiffness index, are independent predictors of macrovascular disease in patients with type 2 diabetes mellitus

E. Laugesen[1], N.B. Rossen[1], P.L. Poulsen[1], K.W. Hansen[2], E. Ebbehøj[1], S.T. Knudsen[2,1];
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, [2]Department of Internal Medicine, Regional Hospital Silkeborg, Denmark.

Background and aims: Patients with type 2 diabetes mellitus are at increased risk of cardiovascular disease (CVD). We examined the predictive ability of ambulatory blood pressure monitoring (ABPM) parameters for fatal and non-fatal CVD in patients with type 2 diabetes mellitus.
Material and methods: 108 patients with type 2 diabetes mellitus (mean duration 6.6 years) were followed for 9.5 (0.5-14.5) years. At baseline, all patients underwent ABPM.
Results: 45 patients experienced at least one CV event (35 non-fatal and 10 fatal). In bivariate analysis, CVD during follow-up was predicted by 24-h ambulatory pulse pressure (PP), ($p<0.01$), ambulatory arterial stiffness index (AASI), 24-h systolic blood pressure (BP) and systolic and diastolic non-dipping (defined as less than 10% nightly BP reduction) ($p<0.05$ for all). In Cox regression analysis with adjustment for established risk markers, 24-h PP and systolic night:day BP ratio both independently predicted CVD during follow-up: the adjusted hazards ratio (HR) for subsequent CVD per 10 mmHg increase in 24-h PP was 1.37 (95%CI 1.01;1.89, $p<0.05$), and the HR per 10 % increase in systolic night:day BP ratio was 1.54 (95CI 1.03; 2.30, $p<0.05$). Only 8 out of 31 (26%) patients with both 24-PP below the median (57 mmHg) and normal nocturnal systolic BP dipping pattern had incident CVD during follow up, whereas 19 out of 28 patients (68%) with both 24-h PP above or equal to the median and systolic non-dipping had incident CVD ($p<0.01$), figure 1.
Conclusion: 24-h PP and impaired nocturnal systolic BP decline, but not AASI, were independent predictors for CVD in type 2 diabetes patients.

Mechanisms of effect of weight loss on blood pressure

L. Flores[1], R. Morínigo[1], J. Vidal[1], J. Viaplana[2], E. Esmatjes[3];
[1]Obesity Unit, Clinic Hospital, [2]Obesity Unit, Institut d'Investigacions Boimèdiques August Pi i Sunyer, [3]Diabetes Unit, Clinic Hospital, Barcelona, Spain.

Weight loss has a clear blood pressure-lowering effect, the pathophysiological mechanisms are not completely understood. The aim of this study was to evaluate the effect of significant weight loss on blood pressure (BP) and its pathological mechanisms.
Patients and methods: Patients with documented hypertension who underwent laparoscopic gastric bypass were studied. Antihypertensive treatment was withdrawn one week before the evaluation. Anthropometric, BP (24-h ambulatory BP measurement) assessment, and blood samples for renin-angiotensin-aldosterone system [RAAS, plasma renin activity (PRA), aldosterone, angiotensin II and angiotensin converting enzyme] and sympathetic nervous system (metanephrine, normetanephrine and noradrenaline) analysis were performed before surgery at 4 and at 12 months postoperatively.
Results: Eighteen patients were studied, 12 females, with 50.8 (38-63) years old, with hypertension duration of 6.4 (1-20) years and excess body weight of 55.6 (36-73) kg. Twelve months after surgery: the BMI decreased from 45.6 to 32.1 Kg/m^2; excess body weight loss was -37.2 Kg; 13 (72%) patients had completed resolution of hypertension while 5 (28%) patients had improvement; 24-h (systolic -18.8/diastolic -7-7 mmHg), daytime and night-time BP values decreased significantly. The PRA (0.30 to 0.21 ng/mL*h), aldosterone (5.3 to 3.1 ng/dl) and noradrenaline (121.5 to 77.5 pg/mL) also had a significant decrease.
Conclusion: Weight loss is associated with reduction of the BP, RAAS and sympathetic system in obese hypertensive subjects.

1290

Assessment of pulsepen for detection of pseudohypertension in diabetic patients

C. Cugnet Anceau[1], A. Serusclat[2], X. André-Fouet[3], G. Finet[3], G. Rioufol[3], F. Gueyffier[3], P. Douek[2], P. Moulin[1];
[1]U11 Fédération d'endocrinologie, [2]Service d'imagerie Hôpital Cardiologique, [3]Service de cardiologie, Bron, France.

Background and aims: In the diabetic population, hypertension is often severe and resistant despite the combination of several antihypertensive drugs. Stiffness of brachial arteries may induce an overestimation of intra-arterial

blood pressure (BP) called pseudohypertension. Evidence for pseudohypertension is difficult to establish in clinical practice. A new non invasive method (Pulsepen) based on the estimation of central aortic pressure by applanation tonometry has been proposed for this purpose but was not previously assessed in diabetic patients.
Materials and methods: To compare Pulsepen and Dinamap versus intra-arterial pressure (method of reference) and to assess the capacity of Pulsepen to screen pseudohypertension in diabetic patients with resistant hypertension, BP was simultaneously recorded in diabetic patients by the three methods during an endovascular procedure (arteriography or coronarography).
Results: Our study population included 11 type 2 diabetic patients (7 men and 4 women), aged 66.5±6.9 years, with a duration of diabetes of 23.7±5.4 years, a mean BMI of 31.5±5.5 kg/m^{2}and a mean HbA1c level of 8.5±1.5%, with persistent hypertension despite two antihypertensive drugs at the time of inclusion. Seven patients were in secondary prevention of cardiovascular disease. Systolic BP (SBP) was significantly underestimated by: - 10.6± 8.24 % with Pulsepen (p=0.009) and by -4.63± 6.89 % with Dinamap (p=0.04). Diastolic BP (DBP) was insignificantly overestimated of +11.7±19.5 % (p=0.09) and by +15.3±19.9 % (p=0.06), respectively. The regression coefficients versus intra-arterial values were: SBP r^2 0.82 (p=0.0001), DBP r^2 0.64 (p=0.002) for Pulsepen and SBP r^2 0.87 (p<0.001), DBP r^2 0.65 (p=0.002) for Dinamap. According to pseudohypertension determined from the dinamap measurements, one patient had systolic pseudohypertension and two patients diastolic pseudohypertension. The Pulsepen was unable to detect the 3 cases of pseudohypertension.
Conclusion: Our data suggest that Pulsepen is not a reliable method in order to estimate intraarterial BP and to detect pseudohypertension in diabetic patients with resistant hypertension. This study underlies the difficulties to accurately measure BP in diabetic patients.

Systolic, Diastolic, Mean, Pulse blood pressure differences

	Pulsepen BP-intraarterial BP (mmHg)	p	Dinamap BP-Intraarterial BP (mmHg)	p
SBP	- 18.8 ± 15.5	0.009	- 8.7 ± 12.3	0.04
DBP	+ 7.6 ± 15.1	0.09	+ 10.1± 15.4	0.06
Mean BP	- 3.2 ± 10.7	0.26	+ 3.8 ± 9.9	0.09
Pulse BP	- 28.6 ± 24.7	0.03	- 18.8 ± 22.3	0.004

A proteomic approach to the long-term experimental hypertensive-diabetic myocardium

Ó. Lorenzo[1], B. Picatoste[1], S. Ares[1], A. Caro[2], E. Ramírez[1], E. Camafeita[3], J.A. López[3], J. Egido[1], J. Tuñón[1];
[1]Vascular Pathology, Instituto de Investigaciones Sanitarias Fundación Jiménez Díaz, [2]Veterinary Faculty, Universidad Complutense de Madrid, [3]Unidad de Proteómica, Centro Nacional de Investigaciones Cadiovasculares, Madrid, Spain.

Background and aims: Diabetes is a worldwide pandemic that may damage the heart. Myocardial protein alteration has been described in short-term injury. However there is not information about the chronic pathology and its association with hypertension.
Aim: To analyze the myocardial proteome and molecular pathways of long-term diabetic/hypertensive rats.
Materials and methods: Normotensive and spontaneously hypertensive (SHR) rats received either streptozotocin or vehicle. After 22 weeks, type-I diabetic (DM1), SHR, DM1/SHR and control rats were sacrificed and the left ventricles studied by a proteomic approach based on DIGE and MALDI-MS. Differential proteins were validated by immuno-histochemistry, Western blot and Electrophoretic Mobility Shift assay (EMSA) and clustered into different biochemical pathways using bioinformatics tools.
Results: Long-term DM1 and hypertensive hearts are characterized by hypertrophy, fibrosis and apoptosis. By proteomics, we found 29, 55 and 58 proteins altered in the myocardium of long-term DM1, SHR and DM1/SHR rats, respectively (ratio≥ 1.35-fold with p≤0.05). Among these, DM1 myocardium presented over-expression of cytoskeleton and apoptosis proteins and down-regulation of anti-apoptotic and mitochondrial metabolic enzymes. In SHR and DM1/SHR rats these changes were exacerbated and, in addition, fatty acid ß-oxidation enzymes were decreased. Other enzymes for amino acid and alcohol metabolism were also altered. Bioinformatics suggested the implication of specific cytoskeleton factors, cytokines and fatty acid nuclear receptors in these pathologies. Peroxisome-activated receptors (PPARs) were stimulated whereas hepatocyte nuclear factor-4α receptor (HNF-4α) was not.
Conclusion: Long-term DM1 and markedly SHR and DM1/SHR hearts presented altered proteomes. Down-regulation of fatty acid and carbohydrate metabolisms and up-regulation of hypertrophic and apoptotic proteins may contribute to the hypertensive and diabetic-hypertensive cardiomyopathy. New unveiled factors as fatty acid nuclear receptors may be used as potential therapeutic targets for these diseases.

1292

In subjects with type 2 diabetes, liraglutide, a once-daily human GLP-1 analogue, reduces systolic blood pressure with negligible impact from weight loss

V.A. Fonseca[1], R.R. Henry[2], R. Tabanera y Palacios[3], J. Brett[3], J. Plutzky[4];
[1]Tulane University Medical Center, Tulane University Health Sciences Center, New Orleans, [2]University of California, San Diego, [3]Novo Nordisk Inc, Princeton, [4]Harvard Medical School, Brigham & Women's Hospital, Boston, USA.

Background and aims: Hypertension is a major risk factor for myocardial infarction and stroke, and is more common in individuals with type 2 diabetes (T2D) than in the general population. Modest weight loss can result in significant long-term reductions in blood pressure and thereby reduce the risk for hypertension. In phase 3 clinical trials, in addition to improving glycated haemoglobin (HbA_{1c}) by 1.0-1.5%, liraglutide also improved systolic blood pressure (SBP) by 2-7 mmHg and produced sustained body weight (BW) reductions of 2-3 kg. However, the specific nature of the relationship between the effect of liraglutide on SBP and BW is not well-characterised.
Materials and methods: A meta-analysis of six randomised phase 3 clinical trials (n=3967) was performed in the liraglutide (1.2 and 1.8 mg) and placebo arms to investigate the relationship between changes in SBP and BW from baseline at each post-randomisation visit up to 26 weeks using an analysis of covariance (ANCOVA) model with treatment, trial, previous OAD treatment as fixed effects, country as random effect, and change in BW from baseline as covariate. The percentage of the change in SBP predicted by the change in BW is given by the 100 × R^2 (the square of the Pearson correlation coefficient), a goodness-of-fit index. The closer the R^2 is to 1, the stronger the relationship between change in SBP and BW.
Results: The analyses show a consistent trend of a very weak correlation between change in SBP and change in BW over time. At Week 2, up to 2% of the change in SBP could be predicted by the change in BW for both liraglutide doses and placebo. At Week 26, both liraglutide arms and placebo had a percentage of R^2 below 2%. The Pearson correlation between the change in SBP and the predicted change in SBP obtained from the ANCOVA model was also very weak with R^2 below 4%.
Conclusion: A minimal amount of the observed effect of liraglutide on change in SBP is predicted by change in BW. As a result, the effect of liraglutide on SBP cannot be explained by weight loss alone. In order to better understand the effect of liraglutide on SBP, mechanistic studies are warranted.

The prevalence and severity of hypertension in patients with type 2 diabetes of Yemenite origin is lower than in non-Yemenite diabetics

M. Blaychfeld Magnazi[1], N. Reshef[1], T. Zornitzki[1], S. Weitzman[2], H. Knobler[1];
[1]Metabolic Unit, Kaplan Medical Center, Rehovot, [2]Department of Epidemiology, Ben-Gurion University of the Negev, Beer-Sheva, Israel.

Background and aims: Yemenite Jews who immigrated to Israel during the years 1948-1950 had a very low prevalence of diabetes (0.05%) which increased to 12% within 40 years in parallel with their lifestyle changes. However, previous limited data suggested that the prevalence of hypertension (HTN) in Yemenite Jews remained lower than the prevalence in the general Israeli population. The aims of the current study were to determine in a group of patients with type 2 diabetes of Yemenite (Y-DM) or non-Yemenite (NY-DM) origin the prevalence of HTN and lifestyle patterns including their adherence to the Dietary Approaches to Stop Hypertension (DASH) diet.
Materials and methods: A cross-sectional study of 63 Y-DM patients (2 parents of Yemenite origin) and 120 NY-DM patients (neither parent of Yemenite origin) was conducted at a Diabetes Clinic. Medical and lifestyle information was collected including food frequency questionnaire (FFQ).
Results: The age and sex distribution were similar in the Y-DM and NY-DM groups (63 ± 7 years vs. 64 ± 7 years; 57% males vs. 56% males, respectively). The duration of diabetes in the Y-DM group was 16 ± 10 years vs. 13 ± 9 years in the NY-DM (P = 0.07) and the Y-DM group had lower weight and waist circumference (72 ± 13 kg vs. 85 ± 17 kg and 95 ± 11 cm vs. 105 ± 13 cm, P < 0.001). The prevalence of HTN was significantly lower in the Y-DM group compared with the NY-DM group (63% vs. 83%, P= 0.003). Despite having similar blood pressure control, patients in the Y-DM group necessitated less blood pressure medications than patients in the NY-DM (1.6 ± 1.8 vs. 2.5 ± 1.7, P= 0.002). In addition, in only 30% of the Y-DM group HTN was diagnosed before or concomitantly with the diagnosis of diabetes compared with 51% in the NY-DM (P= 0.035). In a logistic regression analysis, Non-Yemenite origin was independently associated with a higher prevalence of HTN (odd ratio 3.0, 95% CI :1.5-6.3, P= 0.0025). There were no significant differences between the 2 groups in physical activity, total calories consumed and the DASH score (30 ± 3 vs. 31 ± 3).
Conclusion: Despite the marked increase in the prevalence of type 2 diabetes in Yemenite Jews who immigrated to Israel, the prevalence of HTN in diabetics of Yemenite origin remained significantly lower compared with Non-Yemenite diabetics and blood pressure control necessitated less medications. These results are not due to differences in life style including adherence to the DASH diet and other mechanisms have to be explored.

Colesevelam for Hispanic patients with hypercholesterolaemia and prediabetes

Y. Handelsman[1], R.B. Goldberg[2], J. Rosenstock[3], W.T. Garvey[4], V.A. Fonseca[5], E. Hernandez-Triana[6], M.R. Jones[7], Y.-L. Lai[7], X. Jin[8], S. Misir[7], S. Nagendran[7], S.L. Abby[7];
[1]Metabolic Institute of America, Tarzana, USA, [2]University of Miami Miller School of Medicine, Miami, USA, [3]Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, [4]UAB Diabetes Research and Training Center, University of Alabama at Birmingham, USA, [5]Tulane University Health Sciences Center, New Orleans, USA, [6]Endocare Research Institute, Universidad del Rosario, Bogota, Colombia, [7]Daiichi Sankyo, Inc., Parsippany, USA, [8]Daiichi Sankyo Pharma Development, Edison, USA.

Background and aims: Both hypercholesterolemia and prediabetes increase cardiovascular disease risk. Colesevelam has been shown to reduce LDL-C and fasting plasma glucose (FPG) in patients (pts) with hypercholesterolemia and prediabetes. A 16-week (wk), randomized, double-blind, placebo-controlled, multinational study evaluated the lipid- and glucose-lowering effect of colesevelam in pts with hypercholesterolemia and prediabetes.
Materials and methods: This post-hoc analysis evaluated the effect of colesevelam in a subpopulation of Hispanic pts (those self identified enrolled in Colombia, Mexico, and the US) included in the 16-wk study. Adults with untreated prediabetes (2-h post-OGTT glucose: 7.8-11.1 mmol/L and/or FPG: 6.1-6.9 mmol/L), LDL-C ≥2.6 mmol/L, and triglycerides (TG) <5.7 mmol/L were randomized 1:1 to colesevelam 3.75 g/d or placebo. Primary endpoint was percent change in LDL-C from baseline to Wk 16. All efficacy analyses were performed using last observation carried forward at Wk 16.
Results: In total, 153 Hispanic pts received colesevelam (n=77) or placebo (n=76). There was a significant LS mean percent change with colesevelam vs placebo from baseline to Wk 16 in: LDL-C (-14.7% vs 4.8%; treatment difference [TD]: -19.4%; *P*<0.0001), non-HDL-C (-10.2% vs 1.8%; TD: -12.0%; *P*<0.0001), total cholesterol (-6.9% vs 2.8%; TD: -9.7%; *P*<0.0001), apoB (-8.0% vs 2.2%; TD: -10.2%; *P*=0.0002), and TG (median: 5.9% vs -8.1%; TD: 15.4%; *P*=0.003). ApoA-I increased with both colesevelam (5.0%) and placebo (4.4%) at Wk 16. A significantly greater proportion of pts achieved LDL-C <2.6 mmol/L with colesevelam vs placebo at Wk 16 (27% vs 11%; *P*=0.002). Colesevelam vs placebo also produced significantly greater reductions from baseline in FPG (median: -0.2 vs -0.1 mmol/L; TD: -0.1 mmol/L; *P*=0.024) and HbA_{1c} (mean: -0.14% vs -0.02%; TD: -0.12%; *P*=0.009) at Wk 16. The proportion of pts achieving normalization of glucose (FPG <5.6 mmol/L) was significantly greater with colesevelam vs placebo (44% vs 23%; *P*=0.0497). Overall, colesevelam was well tolerated in Hispanic pts with hypercholesterolemia and prediabetes (Table).
Conclusion: In Hispanic pts with hypercholesterolemia and prediabetes, colesevelam may be a suitable option for lowering LDL-C and improving the metabolic profile. Further investigation regarding the effect of colesevelam on progression to type 2 diabetes is warranted.

Summary of Adverse Events		
n (%)	Colesevelam (n=81)	Placebo (n=78)

Meta-analysis evaluating the proportions of patients with and without diabetes achieving lipid/lipoprotein goals with ezetimibe/statin combination therapy versus statin alone

P. Brudi[1], J.R. Guyton[2], J. Betteridge[3], M. Farnier[4], L.A. Leiter[5], J. Lin[6], A. Shah[6], A.O. Johnson-Levonas[6];
[1]Merck Sharp & Dohme Corp, Whitehouse Station, USA, [2]Duke University Medical Center, Rahleigh, USA, [3]Royal Free & University College London Medical School, USA, [4]Point Medical, Dijon, France, [5]4Keenan Research Centre in the Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, Canada, [6]Merck Sharp & Dohme Corp, Rahway, USA.

Background and aims: Treatment guidelines identify low-density lipoprotein cholesterol (LDL-C) as a major target of treatment in hypercholesterolemic patients with non-high-density lipoprotein cholesterol (non-HDL-C), apolipoprotein (apo) B and high-sensitivity C-reactive protein (hs-CRP) as secondary targets or emerging risk factors. This meta-analysis compared proportions of hypercholesterolemic patients with and without diabetes achieving various targets specified levels following treatment with ezetimibe 10 mg plus statin therapy (pooled across statin dose/type; EZE/statin) versus statin monotherapy (pooled across statin dose/type).
Materials and methods: This was a pooled analysis of 27 previously published, randomized, double-blind, active or placebo-controlled clinical trials conducted in 21794 adult patients (age range: 18-81 yr) with elevated LDL-C (LDL-C range: 1.81-6.48 mmol/L) receiving EZE/statin or statin alone for 4-24 wk. Patients were classified as having diabetes (either type 1 or 2). This analysis evaluated % of patients achieving various treatment goals at study endpoint in patients with (n=6541) and without diabetes (n=15253). Adjusted odds ratios (95% CIs) were calculated to evaluate the between-treatment ability to achieve specified levels in the overall population and within subgroups.
Results: Calculated odds ratios for the single levels are presented in the Table. Significantly more patients with and without diabetes achieved LDL-C (<2.59, <1.99, and <1.81 mmol/L), non-HDL-C (<3.37 and <2.59 mmol/L), apo B (<0.9 and <0.80 g/L) and hs-CRP (<2 and <1 mg/L) levels with EZE/statin vs statin alone. Patients with diabetes were more likely to reach single LDL-C and apo B targets than were non-diabetes patients. Greater goal attainment rates with EZE/statin vs statin alone also were seen for the dual (LDL <2.59 mmol/L and apo B <0.9 g/dL, LDL-C <1.81 mmol/L and apo B <0.8 g/L, LDL-C <1.99 mmol/L and apo B <0.8 g/L as well as hs-CRP <2 mg/L and LDL-C <2.59 mmol/L) and triple targets (LDL-C <2.59 mmol/L and apo B <0.9 g/L and non-HDL-C <3.37 mmol/L as well as LDL-C <1.81 mmol/L and apo B <0.8 g/L and non-HDL-C <2.59 mmol/L) both in the overall population and by diabetes status.
Conclusion: In this meta-analysis, significantly more patients with and without diabetes achieved specified LDL-C, non-HDL-C, apo B and hs-CRP levels with treatment with EZE/statin combination therapy vs statin monotherapy. The goal attainment for LDL-C, non-HDL-C and Apo B were significantly greater in patients with diabetes than those without diabetes.

	Overall Population			With Diabetes		Without Diabetes	
Goal	Eze/Statin vs. Statin	OR[a] (95% CI)	OR[b] (95% CI)	Eze/Statin vs. Statin	OR[c] (95% CI)	Eze/Statin vs. Statin	OR[d] (95% CI)
LDL-C <2.59 mmol/L	75% vs. 52%	4.23 (3.95, 4.53)	1.41 (1.30, 1.52)	85% vs. 65%	4.90 (4.25, 5.66)	71% vs. 46%	4.04 (3.73, 4.37)
LDL-C <1.99 mmol/L	45% vs. 23%	3.06 (2.70, 4.25)	1.47 (1.36, 1.58)	59% vs. 34%	4.59 (4.05, 5.19)	38% vs. 18%	3.70 (3.40, 4.02)
LDL-C <1.81 mmol/L	33% vs. 15%	4.02 (3.72, 4.34)	1.48 (1.37, 1.60)	48% vs. 25%	4.59 (4.04, 5.22)	27% vs. 11%	3.70 (3.36, 4.07)
Non-HDL-C <3.37 mmol/L	75% vs. 53%	4.13 (3.85, 4.43)	1.30 (1.21, 1.41)	82% vs. 63%	4.48 (3.90, 5.16)	72% vs. 49%	4.01 (3.70, 4.35)
Non-HDL-C <2.59 mmol/L	41% vs. 21%	3.81 (3.55, 4.09)	1.27 (1.18, 1.36)	52% vs. 29%	4.38 (3.85, 4.98)	36% vs. 17%	3.55 (3.26, 3.88)
Apo B <0.9 g/L	45% vs. 29%	2.88 (2.69, 3.09)	1.23 (1.14, 1.32)	55% vs. 38%	3.17 (2.79, 3.59)	41% vs. 25%	2.75 (2.53, 2.99)
Apo B <0.8 g/L	20% vs. 10%	3.09 (2.85, 3.35)	1.10 (1.02, 1.20)	37% vs. 22%	3.37 (2.93, 3.87)	25% vs. 13%	2.93 (2.65, 3.23)
hs-CRP <2 mg/L*	56% vs. 52%	1.20 (1.12, 1.28)	0.84 (0.78, 0.91)	50% vs. 46%	1.20 (1.06, 1.36)	59% vs. 55%	1.19 (1.10, 1.30)
hs-CRP <1 mg/L*	31% vs. 28%	1.25 (1.16, 1.34)	0.93 (0.86, 1.10)	27% vs. 25%	1.19 (1.03, 1.37)	33% vs. 29%	1.27 (1.16, 1.39)

[a]Based on logistic model with terms for first-second line, diabetes, treatment, and baseline value(s), odds ratio and 95% CI of attaining goal on EZE/Statin versus Statin.
[b]Based on logistic model with terms for first-second line, treatment, and baseline value(s), odds ratio and 95% CI of attaining goal on EZE/Statin versus Statin.
[c]Based on logistic model with terms for first-second line, diabetes, treatment, and baseline value(s), odds ratio and 95% CI of attaining goal for diabetic versus non-diabetic patients.
*The magnitudes of differences in goal attainment rates between the two treatments were small but statistically significant.

Comparative efficacy of fenofibrate/pravastatin/ezetimibe and simvastatin/ezetimibe therapies in type 2 diabetic patients with combined hyperlipidaemia and cardiovascular disease

M. Farnier[1], A. Steinmetz[2], A. Csaszar[3], K. Retterstol[4], M. Dluzniewski[5];
[1]Point Médical, Dijon, France, [2]St Nikolaus-Stiftshospital GmbH, Andernach, Germany, [3]State Health Center, Budapest, Hungary, [4]Oslo University Hospital - Rikshospitalet, Norway, [5]Warsaw Hospital, Poland.

Background and aims: Very high risk patients with type 2 diabetes (T2D) and cardiovascular disease often require combination therapy to achieve recommended LDL-cholesterol (LDL-C) and non HDL-cholesterol (non-HDL-C) goals. This study evaluated the efficacy and safety of Fenofibrate (F) 160 mg/Pravastatin (P) 40 mg fixed dose combination and Ezetimibe (E) 10 mg compared to Simvastatin (S) 20 mg and E10 mg in T2D patients with cardiovascular disease and not at goals on S20 mg.
Materials and methods: This randomized, double-blind, parallel group study was conducted at 73 European centers. After a 6-week run-in period on S20 mg, 273 patients with non-HDL-C ≥ 100 mg/dL or LDL-C ≥ 70 mg/dL and triglycerides (TG) 150-600 mg/dL were randomized (week 0) for a 12-week treatment period to the F160 mg/P40 mg and E10 mg triple therapy or the combination of S20 mg and E10 mg, followed by a 12-week open-label period where all patients received the triple therapy. The primary efficacy comparison was the mean percent (%) changes in non-HDL-C (F/P+E vs S+E). Secondary end-points included LDL-C, HDL-C, TG, ApoB and fibrinogen.
Results: At week 12, no significant differences were observed between the F160/P40+E10 group and the S20+E10 group in reducing non-HDL-C (-21.2% vs -24.7%; p=0.09) and ApoB (-15.7% vs -18.1%; p=0.149), and in increasing HDL-C (+3.5% vs +0.5%; p=0.066). The changes in LDL-C were -19.8% in the F160/P40+E10 group and -25.1% in the S20+E10 group (p=0.05). The triple therapy was more effective than S20+E10 in reducing TG (-22.8% vs -8.2%; p=0.007) and fibrinogen (-11.8% vs +0.6%; p<0.0001). The triple therapy was generally well tolerated with a safety profile comparable to the S20+E10 combination therapy. Especially no cases of myopathy or rhabdomyolysis were reported.
Conclusion: The Fenofibrate160 mg/Pravastatin 40 mg fixed-dose combination associated with Ezetimibe 10 mg was a new alternative to improve the global atherogenic lipid profile in T2D patients with combined hyperlipidemia in secondary prevention.

Effect of one year treatment with insulin and oral glucose-lowering agents on lipid levels in non-obese patients with type 2 diabetes

S.S. Lund[1], L. Tarnow[1], B.B. Nielsen[1], B.V. Hansen[1], M. Frandsen[1], O. Pedersen[2], H.-H. Parving[3], A.A. Vaag[1];
[1]Steno Diabetes Center, Gentofte, [2]Hagedorn Research Institute, Gentofte, [3]Dep of Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark.

Background and aims: In non-obese patients with type-2 diabetes (T2DM), metformin has been suggested to improve cholesterolaemia more so than an insulin secretagogue despite similar glycaemic control. Also, the cholesterol-lowering effect of metformin has been suggested to be enhanced by concomitant statin therapy. It is unknown if these effects persist when treatments are combined with insulin therapy. We aimed to study the effect of repaglinide (an insulin secretagogue) versus metformin both in combination with insulin therapy on lipid levels in non-obese T2DM patients. Furthermore, the effect of statin use was of interest.
Materials and methods: 101 non-obese T2DM patients (BMI ≤27 kg/m^2) with HbA_{1c} ≥6.5% on oral agents were randomised to one year treatment with insulin (biphasic insulin aspart 70/30) in combination with either repaglinide 6 mg or metformin 2g (double-masked). Insulin doses were adjusted aiming for HbA_{1c}<6.5%. Those patients who did not start or stop statin therapy during follow-up were analysed (n=88).
Results: In statin users, insulin plus metformin (n=43) significantly lowered fasting total and Non-HDL cholesterol (Non-HDLC) compared with insulin plus repaglinide (n=40) (mean [95% CI] baseline-adjusted difference between treatments for Non-HDLC: −0.26 mmol/l [−0.49; −0.02], p=0.039). In patients not using statins (n=5), no statistical significant differences of plasma lipid levels was observed between patients using insulin plus metformin versus insulin plus repaglinide. Conclusions were similar after adjusting for

changes in statin doses. Insulin doses and HbA_{1c} were similar between treatments (previously reported).
Conclusion: In non-obese T2DM patients using statins one-year treatment with insulin plus metformin rather than insulin plus an insulin secretagogue might improve proatherogenic cholesterolaemia. This supports potential cardioprotective effects of metformin when combined with insulin even in statin users.

Loss of the association between plasma Pro-protein Convertase Subtilisin/Kexin type 9 (PCSK9) and LDL-apoB100 catabolism in type 2 diabetes
B. Vergès[1,2], P. Costet[3], L. Duvillard[2], M.-C. Brindisi[2], M. Krempf[3], B. Cariou[3]; [1]Endocrinology-Diabetology, Hôpital du Bocage, Dijon, [2]INSERM CRI866, Dijon, [3]INSERM U915, Nantes, France.

Background and aims: Pro-protein convertase subtilisin/kexin type 9 (PCSK9) is an important regulator of LDL metabolism because of its ability to facilitate degradation of LDL-receptors. It has recently been shown, in non-diabetic men, that plasma PCSK9 level was inversely correlated with LDL apoB100 fractional catabolic rate (FCR) suggesting an influence of plasma PCSK9 on LDL catabolism. However, the association between plasma PCSK9 and LDL catabolism remains unknown, in patients with type 2 diabetes.
Materials and methods: This prompted us to perform a kinetic study of LDL-apoB100, using C^{13} leucine, in 38 individuals (20 men, 18 women) including 23 non diabetic normolipidemic subjects and 15 patients with type 2 diabetes.
Results: Plasma PCSK9 levels were not significantly different between non diabetic subjects and patients with type 2 diabetes (271 ± 109 vs. 301 ± 96 ng/ml). In the non diabetic group, plasma PCSK9 was positively correlated with age (r=0.38, p=0.018), LDL-cholesterol (r= 0.43, p=0.006), apoB (r=0.44, p=0.005) and inversely correlated with LDL-apoB100 FCR (r=-0.52, p=0.001). In multivariate analysis, LDL-apoB100 FCR was independently associated with PCSK9 (p=0.0006) and gender (p=0.038), but not with age or BMI. Plasma PCSK9 concentration explained, in this non diabetic population, 37% of the variance in LDL-apoB100 FCR. On the other hand, in the population with type 2 diabetes no correlation was found between plasma PCSK9, on the one hand, and LDL-cholesterol, apoB and and LDL-apoB100 FCR, on the other hand. In both groups, no correlations were found between plasma PCSK9 and LDL-apoB Production Rate.
Conclusion: Our data indicate that plasma PCSK9 influences significantly the catabolism of LDL-apoB100 in individuals without diabetes but not in patients with type 2 diabetes. The reasons for this loss of association between plasma PCSK9 and LDL catabolism, in type 2 diabetes, remain to be determined.

Effects of extended release niacin/laropiprant on lipoprotein subfractions in patients with type 2 diabetes mellitus
E. O'Neill[1], A. MacLean[1], H. Giezek[2], D. Maccubbin[1]; [1]Merck Sharp & Dohme Corp, Rahway, USA, [2]Merck Sharp & Dohme Corp, Brussels, Belgium.

Background and aims: Lipid management guidelines emphasize reducing LDL cholesterol as the primary goal of pharmacologic treatment. However other lipoprotein parameters, including increased plasma concentrations of small LDL, and IDL particles, and reduced plasma concentration of medium/large HDL particles, may also place patients at increased risk for coronary heart disease. Patients with T2D are especially prone to this atherogenic lipoprotein phenotype Extended release niacin/laropiprant (ERN/LRPT) is a fixed-dose combination tablet containing 1 g of ERN and 20 mg of LRPT, a prostaglandin D_2 receptor antagonist that reduces ERN-induced flushing while preserving ERN's LDL-C and triglyceride lowering, and HDL-C raising effects. In this assessment, the effects of 12 weeks of treatment with ERN/LRPT in patients with T2D on plasma lipoprotein particles were evaluated.
Materials and methods: In a multicenter, double-blind, placebo-controlled, 36-week study, T2D patients (n=796) were randomized 4:3 to ERN/LRPT (1 tablet / day) or placebo (PBO). After 4 weeks 2 tablets / day of ERN/LRPT were given for the remainder of the study. HDL, LDL, VLDL, and chylomicron particle size and concentration were evaluated at week 12 by NMR. Lipoprotein subfraction data are reported as summary statistics without adjustment for covariates.
Results: At week 12, ERN/LRPT produced significant_(p≤0.001 for all) changes in LDL-C (-17.9%), HDL-C (23.2%), and triglycerides (-23.1%). Compared with PBO, ERN/LRPT treatment was associated with a relative shift in the plasma concentration of HDL particles from small to large diameter, and a decrease in the plasma concentrations of all LDL and IDL particles (Table). ERN/LRPT also produced large reductions in the plasma concentrations of all VLDL and chylomicron particles relative to PBO.
Conclusion: In patients with T2D, 12 weeks of treatment with ERN/LRPT shifted the overall lipoprotein profile toward a potentially less atherogenic pattern: reducing the plasma concentration of small LDL and IDL particles and increasing the plasma concentration of large HDL particles compared with PBO.

	PLASMA LIPOPROTEIN CONCENTRATIONS MEDIAN baseline / MEDIAN CHANGE from Baseline at Week 12 *

Role of HDL glycation and glycoxidation in counteracting the inhibitory effect of oxidized LDL on endothelium-dependent vasorelaxation
M.-C. Brindisi[1,2], L. Perségol[2], L. Duvillard[2], D. Rageot[3], B. Vergès[1,2]; [1]Diabetology, Teaching Hospital, [2]Physiopathology of dyslipidemia, Inserm Research Center 866, [3]Research Federative Institute 100, Teaching Hospital, Dijon, France.

Background and aims: In healthy normolipidaemic and normoglycaemic control subjects, HDL are able to reverse the inhibition of vasodilation induced by oxidized LDL. We have previously shown that in type 1 diabetic patients, HDL do not protect against the inhibition of endothelium dependant vasorelaxation induced by oxidized LDL. This defect was not explained by abnormalities in HDL composition, size or paraoxonase activity. The aim of this study was to analyse the role of glycation or glycoxidation of HDL on this vasodilation effect.
Materials and methods: Blood samples were collected from healthy patients. Extracted HDL particles, separated by ultracentrifugation, were glycated or glycoxidized in vitro. Vasoreactivity was evaluated by the relaxation response to acetylcholine of rabbit aorta rings pre-contracted with noradrenaline, before and after two hours incubation with or without different lipoprotein fractions (Krebs'buffer; ox-LDL; normal, glycated or glycoxidized HDL alone; normal, glycated or glycoxidized HDL + ox-LDL).
Results: The lipid composition of normal, glycated and glycoxidized HDL was similar. The mean of the Fructosamine/ApoA1 ratio was 17.58 µmole /g of protein for normal HDL and 48.67 and 53.63 µmole /g of protein for glycated and glycoxidized HDL, respectively. The oxysterol level of glycoxidized HDL was significantly higher than that for normal and glycated HDL (p=0.009 and p=0.016 respectively). Oxidized LDL inhibited endothelium vasodilation (maximal relaxation (Emax) = 53.34 ± 27.06 vs 98.67 ± 10.16 % for incubation in Krebs'buffer, p<0.005). Normal HDL were able to counteract the oxidized LDL-induced inhibition of vasorelaxation (Emax = 78.75 ± 19.72 vs 53.34 ± 27.06 %, p=0.003), whereas glycated and glycoxidized HDL had no effect (p=0.35 and 0.092 respectively). No difference was observed between glycated and glycoxidized HDL (p=0.28).
Conclusion: Our data indicate that glycation of HDL, is responsible for the inability of HDL particles to counteract the oxidized LDL-induced inhibition of endothelium-dependent vasorelaxation. The oxidation of glycated HDL brings no additional effects. Glycation of HDL is probably one important factor that explains the absence of the vasodilation effect of HDL particles in patients with diabetes.

1301

Insulin restores selective insulin resistance in type 2 diabetic mellitus patients with severe hypertriglyceridaemia

S.R. Henderson, R. Maitland, O.G. Mustafa, M. Crook, S.R. Kottegoda; Metabolic Medicine Unit, University Hospital Lewisham, London, United Kingdom.

Introduction: Severe hypertriglyceridaemia (SHTG) is a recognised complication of type 2 Diabetes Mellitus (T2DM) and poses significant risk of premature atherosclerosis and pancreatitis. Altered regulation of triglyceride (TG) metabolism by hepatic and adipose tissue remains critical in T2DM patients. Hyperglycaemia is associated with resistance of hepatic transcription factor *FoxO1* and adipose tissue lipoprotein lipase (LPL) to the actions of insulin, resulting in uncontrolled gluconeogenesis and reduced hydrolysis of serum TG. Conversely, recent research has highlighted that hepatic TG production remains sensitive to circulating insulin, through the activation of transcription factor *SREBP*-1c, perpetuating the detrimental effects of hyperglycaemia and SHTG. We report the novel use of continuous intravenous (IV) insulin to restore this selective insulin resistance and reduce the risk of SHTG in T2DM.
Methods: Patients with hyperglycaemia and SHTG (serum TG >15mmol/L) treated with continuous insulin were retrospectively evaluated within our centre. Demographics, admission details, lipid profiles, glycaemic control and adverse events were recorded. Patients receiving treatment dose heparin were excluded to minimise effect on LPL.
Results: Fifteen patients were reviewed. Mean patient age 46 (27 - 70) years. Patients included 8 Caucasians, 5 Afro-caribbeans and 2 Indo-asians. New onset T2DM was diagnosed in 7 cases. Mean disease duration in the remaining cohort was 60 (2 - 96) months. Median admission HbA1c measured 9.6% (6.1 - 16.1). Pre-admission Insulin was utilised in 75% (n=6) and Metformin in 25% (n=2) patients. Acute pancreatitis was diagnosed in 3 patients prior to insulin infusion. Median admission serum TG measured 26.23mmol/L (15.09 - 48.43) and serum cholesterol 11.24mmol/L (5.39 -19.62). Continuous insulin was infused for an average 48 hours (24 - 72). Median serum TG reduced to 15.79mmol/L (0.79 - 36.59) following 24 hours insulin infusion (n=15) and 12.15mmol/L (5.74 - 32.49) at 48 hours duration (n=8). Insulin infusion continued for 72 hours in 7 patients with median serum TG measuring 10.20mmol/L (5.74 - 24.03). Median discharge serum TG measured 5.75mmol/L (0.79 - 11.66) and serum cholesterol 5.90mmol/L (3.65 - 10.74) correlating with significant reduction in serum TG following IV insulin (p=<0.05). Median length of hospitalisation was 4 days (3 - 15). Concomitant lipid lowering therapy included statins (n=9) and omega-3-acid ethyl esters (n=9). Continued administration of Fenofibrate occurred in 2 patients. Prophylactic low molecular weight heparin was given to all patients (Enoxaparin 20-40mg).
Conclusion: These results detail SHTG associated with hyperglycaemia in a heterogeneous group of T2DM patients ranging from new onset diabetes to established disease. Yet, in all patients, administration of continuous insulin appears to not only achieve normoglycaemia but also dramatically correct SHTG. Insulin stimulates the action of LPL in adipocytes and these findings support this theory owing to the rapid clearance of serum TG. In addition, we speculate that administration of insulin may also regulate gluconeogenesis and hepatic TG synthesis in hyperinsulinaemic patients; restoring selective insulin resistance. Ultimately, the administration of continuous insulin in T2DM patients with SHTG is a simple method of reducing the immediate risk associated with this metabolic complication.

1302

Underutilisation of statins in patients with type 2 diabetes treated with an antihyperglycaemic regimen

L. Radican[1], A.Z. Fu[2], Q. Zhang[1], S.-R. Pentakota[3], T. Seck[4];
[1]Global Outcomes Research, Merck Sharp & Dohme, Corp., Whitehouse Station, [2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, [3]School of Public Health, University of Medicine & Dentistry of New Jersey, Whitehouse Station, [4]Merck Research Laboratories, Rahway, USA.

Background and aims: Patients with type 2 diabetes (T2DM) are at a high risk for cardiovascular (CV) events. Diabetic dyslipidaemia is a key CV risk factor and statin therapy has been demonstrated to reduce CV risk. Therefore use of statins is widely recommended in current treatment guidelines for patients with T2DM. The purpose of this study was to estimate the proportions of patients with T2DM treated with an antihyperglycaemic agent (AHA) who needed a statin therapy based on ADA recommendations and of patients who received statin therapy in clinical practice.
Materials and methods: The study used the GE Healthcare's electronic medical record database, and included patients who were ≥25 years with T2DM and received AHA (oral or insulin) prescription (Rx) between 7/2006 and 6/2008 (index period). The index date was the date of the first AHA Rx within the index period. Patient eligibility for statin therapy according to the ADA Standards of Medical Care in Diabetes (2008) was assessed using patient medical records 1 year prior to (baseline) and 1 year after (follow-up) the index date. Concomitant statin use with AHA therapy was based on Rx records during the follow-up period. Logistic regression was performed to estimate the likelihood of statin use in relation to baseline characteristics, co-morbidities, clinical and laboratory measures, and medication use.
Results: Of the 113,906 patients with T2DM treated with AHAs, 48% were male and mean (SD) age was 63 (13) years. At baseline, LDL-C was ≥ 2.6 mmol/L (100 mg/dL) in 49% of the patients not on a lipid-lowering agent (LLA) and in 34% of the patients on a LLA. While 98% of the patients met ADA eligibility standards for statin therapy, only 64% of patients actually received a statin Rx during the follow-up period. The adjusted logistic regression showed that older age, male, smoking, baseline antihypertensive Rx, and baseline blood thinner Rx are factors associated with increased likelihood of statin use (all p<0.001).
Conclusion: Although nearly all patients with T2DM on AHA were eligible for statin therapy per ADA recommendations, only 64% were treated with statin in our study. This indicates that statins are underused in current clinical practice and a more integrated approach is needed to improve statin utilization to reduce CV risk in patients with T2DM.

Arterial stiffness and endothelial dysfunction in type 1 diabetes mellitus

G. LLaurado[1], M.P. Gil[1], N. Freixenet[1], A. Caixàs[1], O. Giménez-Palop[1], M. Rigla[1], J. Vendrell[2], J.M. González-Clemente[1];
[1]Diabetes, Endocrinology and Nutrition, Hospital de Sabadell, Corporació Sanitària i Institut Universitari Parc Taulí, Sabadell, [2]Diabetes, Endocrinology and Nutrition, Hospital Universitari Joan XXIII. Institut Universitari Pere Virgili. CIBERDEM, Tarragona, Spain.

Background and aims: Subjects with type 1 diabetes mellitus (T1DM) have a very high cardiovascular (CV) risk, which is not fully understood by the classical CV risk factors. Arterial stiffness (AS) could provide some additional information regarding CV risk in these subjects. Endothelial dysfunction is involved in the atherosclerotic process. The studies regarding the relationship between AS and endothelial dysfunction in T1DM are few and contradictory. We aimed at evaluating the relationship between: (1) AS and CV risk factors and (2) AS and endothelial dysfunction.
Materials and methods: Sixty-eight subjects with T1DM were evaluated by (1) sex, age, BMI, WHR, systolic (SBP) and diastolic (DBP) blood pressure, smoking, HbA1c and lipid profile; (2) microvascular complications; (3) insulin resistance (by way of the William's mathematical estimation of the glucose disposal rate -eGDR-); (4) AS assessed as aortic pulse wave velocity (PWV) measured by applanation tonometry (SphygmoCor®) and (5) endothelial dysfunction assessed non-invasively by reactive hyperemia-peripheral arterial tonometry (RH-PAT; EndoPAT2000).
Results: We evaluated 34 men (aged 35.5±9 years, diabetes duration: 14.5±8.5 years, BMI: 26.0±3.3 kg/m2, WHR: 0.91±0.08, SBP: 131.5±10.9 mmHg, DBP: 76.7±7.1 mmHg, smokers: 36.4%, fasting plasma glucose (FPG) 156.2±68.7 mg/dl, HbA1c: 7.4±1.1%, LDL: 100.5±26.1 mg/dl, microvascular complications: 27.3%) and 34 women (aged 35.2±11.2 years, diabetes duration: 12.9±8 years, BMI: 25.3±3.9 kg/m2, WHR: 0.81±0.07, SBP: 118.3±9.6 mmHg, DBP: 69.1±7.9 mmHg, smokers: 35.3%, FPG 172.7±64.0, HbA1c: 7.97±1.2%, LDL 104.5±27.5mg/dl, microvascular complications: 23.5%). In the whole group, PWV correlated positively with age (r=0.53, p<0.001), diabetes duration (r=0.27, p=0.028), BMI (r=0.57, p<0.001), WHR (r=0.38, p=0.001), SBP (0.36, p=0.003) and DBP (r=0.26, p=0.031). In addition, we found a negative correlation between PWV and eGDR (r=-0.31, p=0.011). No association was found between PWV and smoking, lipid profile, FPG, HbA1c, microvascular complications and RH-PAT. In multivariate regression analysis, age (ß=0.46, p<0.001) and BMI (ß=0.40, p<0.001) were the only predictors of PWV (model R=0.686). Although PWV was similar in both genders (men: 7.13±1.34 vs women: 6.86±1.71, p=0.48), in multivariate regression analysis stratifying for sex, age (ß=0.43, p=0.007) and BMI (ß=0.34, p=0.029) were the only predictors of PWV in men (R=0.609) and age (ß=0.29, p=0.020), BMI (ß=0.48, p<0.001) and diabetes duration (ß=0.35, p=0.012) in women (R=0.786).
Conclusion: In subjects with T1DM, the main determinants of PWV were age and BMI. Additionally, diabetes duration was another determinant in women. We did not find any other independent relationship between PWV and the rest of the classical CV risk factors or glycemic control, suggesting that the measurement of PWV could be useful in the assessing of CV risk. Finally, we did not find any association between PWV and endothelial dysfunction measured by RH-PAT.

Endothelial dysfunction and arterial stiffness are linked in hypertensive patients with type 2 diabetes mellitus

E. Russo[1], L. Pucci[1], D. Lucchesi[1], R.M. Bruno[2], E. Storti[1], C. Bianchi[1], G.A. Daniele[1], L. Ghiadoni[2], S. Taddei[2], R. Miccoli[1], G. Penno[1], S. Del Prato[1];
[1]Endocrinology and Metabolism, [2]Internal Medicine, University of Pisa and Azienda Universitaria Ospedaliera Pisana, Pisa, Italy.

Background and aims: In diabetic as well as in hypertensive patients, increased arterial stiffness and endothelial dysfunction both have been both associated with an increased risk of cardiovascular events. Arterial stiffness has been usually ascribed to vascular structural alterations, although a "functional" component contributing to the compliance of large arteries has been demonstrated recently. An inverse correlation between endothelial dysfunction and arterial stiffness was reported in healthy subjects, while this interrelationship has been poorly explored in subjects at high risk of cardiovascular disease, such as patients with hypertension or diabetes. In this study this relationship has been evaluated in hypertensive patients with or without type 2 diabetes mellitus.
Materials and methods: Hypertensive patients with (DM+, n. 69) and without diabetes (DM-, n. 68), matched for age, gender, blood pressure, duration of hypertension and number and class of antihypertensive medications, were included. Brachial artery endothelium-dependent flow-mediated dilation (FMD) and endothelium-independent dilation by 25 μg sublingual glyceryl trinitrate (GTN) were assessed by high-resolution ultrasound and computerized edge detection system. Applanation tonometry was used to measure aortic pulse wave velocity (aPWV), as index of arterial stiffness.
Results: DM+ patients showed higher BMI, waist circumference, blood glucose and HbA1c values, as well lower total, LDL and HDL cholesterol levels compared with DM-. Urinary albumin to creatinine ratio (UACR) was within the normal range in both groups and no difference in hsCRP was found. DM+ showed lower FMD (3.3±2.0 vs 5.0±3.2%, p<0.0001) than DM-, while GTN response was similar. Aortic PWV was higher in DM+ than in DM- patients (10.3±12.2 vs 8.8±1.4 m/s, p<0.0001). The difference remained statistically different (p=0.003) when mean BP, age and BMI were considered as covariates. An increased PWV, defined on the basis of the cut-off of 8.3 m/s, was found in 84% of DM+ and in 64% of DM- (p=0.006). Multiple regression analysis, driven by simple regression, was used to identify independent predictors of aPWV, including in the model age, systolic blood pressure, heart rate, blood glucose, HDL cholesterol, tryglicerides, BMI and waist circumference. Age (r2=0.05, p=0.002), systolic blood pressure (r2=0.08, p=0.001), BMI (r2=0.07, p=0.003), and FMD (r2=0.04, p=0.03), were independently related to PWV (full model r2=0.45). In DM+, FMD (r2=0.11, p=0.003), systolic BP (r2=0.14, p=0.006) and BMI (r2=0.08, p=0.02), remained independent predictors of aPWV (full model: r2=0.33). In DM-, age, but not FMD, was an independent predictor of PWV (r2=0.16).
Conclusion: We demonstrated that increased aortic stiffness is associated with endothelial dysfunction in hypertensive type 2 diabetic patients. The absence of this correlation in normoglycemic hypertensive patients, who have lower aortic stiffness and better endothelial function, suggests specific mechanisms related to the presence of diabetes.

Circulating omentin-1 is associated with endothelial function independently of insulin sensitivity in subjects with altered glucose tolerance

J.M. Fernández-Real, J.M. Moreno-Navarrete, F.J. Ortega, A. Castro, M. Sabater, E. Esteve, W. Ricart;
Department of Diabetes, Endocrinology and Nutrition. Institut d'Investigació Biomédica de Girona. CIBER Fisiopatología de la Obesidad y Nutrición CB06/03/010, Spain.

Background and aims: Omentin-1 is a novel soluble lectin expressed exclusively in the endothelial cells of the blood vessels found in the visceral adipose tissue. Omentin has a vasodilating effect on isolated blood vessels, which is mediated through endothelium-derived NO. To gain insight in the relationship between obesity and cardiovascular risk factors, we aimed to explore the interaction among circulating omentin-1, metabolic parameters and endothelial function according to glucose tolerance status in a human cross-sectional study.
Materials and methods: Circulating omentin-1 (ELISA) was studied in 155 healthy Caucasian men according to glucose tolerance status. Insulin sensitivity was measured using the frequently sampled intravenous glucose tolerance test in 106 subjects. Vascular reactivity was measured by high-resolution ultrasound of the brachial artery in 58 of these subjects.
Results: Circulating omentin-1 concentration was significantly increased in non-obese compared with obese subjects with altered glucose tolerance (AGT, 47.6 ± 15.8 vs. 40.5 ± 13.2 ng/ml, p=0.04). In AGT subjects, serum omentin-1 was negatively associated with obesity parameters [body mass index (r=-0.24, p=0.04), waist to hip ratio (r= -0.25, p= 0.04) and fat mass (r=-0.29, 0.01)], blood pressure [systolic and diastolic blood pressure (r=-0.27, p=0.02 and r=-0.26, p=0.025, respectively)] and circulating IL-6 (r=-0.43, p=0.001) and positively linked to insulin sensitivity (r=0.36, p=0.03), endothelium-independent (r=0.50, p=0.007) and dependent (r= 0.33, p= 0.04) vasodilation. Circulating omentin-1 (p=0.02) and systolic blood pressure (p=0.01) contributed independently to endothelium-dependent but not to endothelium-independent vasodilation variance after controlling for confounding factors in AGT subjects.

Conclusion: Omentin-1 might constitute a biomarker for endothelial function in AGT subjects.

The extent of endothelial dysfunction in polycystic ovarian syndrome is moderated by obesity status
V.S. Sprung[1], D.J. Cuthbertson[2], C.J. Pugh[1], G. Atkinson[1], A. Irwin[2], N. Aziz[3], G.J. Kemp[4], H. Jones[1];
[1]Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, [2]Department of Diabetes and Endocrinology, University Hospital Aintree, [3]Department of Gynaecology, Liverpool Women's Hospital, [4]Magnetic Resonance and Image Analysis Research Centre (MARIARC), University of Liverpool, United Kingdom.

Background and aims: Females with PCOS are at increased risk of cardiovascular disease (CVD). Recent reports suggest that endothelial dysfunction, an early marker of CVD, measured using the flow mediated dilatation (FMD) is evident in PCOS patients. Nevertheless, the supporting evidence remains equivocal, potentially due to differences in obesity and/or insulin resistance which are associated with increased CVD risk and also manifest in PCOS. The aim of this study was to examine the degree to which obesity moderates endothelial function in PCOS patients and controls using a formal meta-analytical approach.
Materials and methods: A systematic review of published studies comparing endothelial function in PCOS patients to control individuals was performed. Nine published and 1 recent unpublished study (PCOS *n*=621; control *n*=297 participants) that measured endothelial-dependent FMD were included. At whole study level PCOS patient demographics included age range of 22.7-35.2 yrs and BMI 23.8-33.8kg/m^2 while control participants age ranged between 21.9-36.7yrs and the BMI from 22.8-37.3 kg/m^2. All participants were normotensive and PCOS patients demonstrated at least two out of the three Rotterdam criteria. The FMD values for PCOS and controls were compared and meta-regressed against BMI. Data are described as mean±SD.
Results: The meta-analysed pooled reduction in FMD was found to be 3.7% (95% CI = 2.7 to 4.8%) in PCOS patients when compared with matched controls (P<0.0005). Significant inter-study heterogeneity was detected (I-square = 68%, P=0.001). Therefore, meta-regression methods were used to explore the impact of BMI status on FMD reduction. The difference in FMD between PCOS and controls was less pronounced (group difference reduced by 0.2% per kg/m2) when participants were obese (P<0.0005). There was no evident publication bias (P=0.52).
Conclusion: There is overwhelming evidence that FMD is lower in PCOS patients compared with controls matched for BMI. Nevertheless, it is apparent from this analysis that the endothelial dysfunction in PCOS is influenced by obesity; with larger differences in FMD between PCOS and control individuals when these individuals are normal weight, suggesting that obesity outweighs the PCOS effect on FMD.

Integrated endothelial function assessment in morbidly obese subjects
M. Pawlowski[1], P. Grzelak[2], M. Saryusz-Wolska[1], E. Szymanska-Garbacz[1], A. Borkowska[1], M. Gilewska[1], J. Loba[1], L. Stefanczyk[2], L. Czupryniak[1];
[1]Diabetology, [2]Radiology, Medical University of Lodz, Poland.

Background and aims: Endothelial function, particularly endothelium-dependent vasodilation is impaired in overweight subjects and is thought to contribute to their increased risk of cardiovascular events. The mechanisms responsible for the adiposity-related reduction in endothelial vasodilatation function are not completely understood. We investigated endothelial function, inflammatory and glucose metabolism parameters in morbidly obese (BMI>40kg/m2) but otherwise healthy subjects.
Materials and methods: We studied 17 (5 men, 12 women, mean age 37,1+/-8,4, BMI 44,14+/-3,9 kg/m2) normotensive obese subjects without prior diabetes diagnosis. 13 age-matched healthy non-overweight subjects served as controls. All subjects underwent oral 75 g glucose tolerance test (OGTT) with plasma insulin measurements. Fasting plasma subclinical inflammation markers (interleukin-6, IL-6; tumor necrosis factor-α, TNF- α), leptin, endothelial dysfunction parameters (intercellular adhesion molecule, ICAM; vascular cell adhesion molecule, VCAM; E-selectin, thrombomodulin) were measured. In addition, endothelial function was assessed in vivo as flow-mediated dilation (FMD) and sublingual nitroglycerin response (nitrate-induced dilation, NID) in the brachial artery in all subjects. Intima-media thickness (IMT) of caroid artery was measured as well.
Results: During OGTT, as compared to the controls, obese subjects had higher glucose level at 60 min (141±38 vs 103±36 mg/dl; p<0.03) and 120 min (121±33 vs 90±28 mg/dl; p<0.03) as well as fasting insulin level (28±25 vs 10±8 μIU/mL; p<0.04) and insulin level at 60 min (115±63 vs 33±21 μIU/mL; p<0.001). Moreover, in the obese subjects HOMA-IR (6.2±5.4 vs 2.34±1.86, p<0.03), TNF-α (24.1±11.0 vs. 13.3±6.9 ng/ml), IL-6 (6.82±4.1 vs 3.85±1.4 pg/ml; p<0.001), leptin (63.2±16.3 vs 26.2±18.1 mg/ml), VCAM (857±312 vs 613±210 ng/ml; p<0.02), sE-selectin (40.7±17.6 vs 25.8±19.6 pg/ml, p<0.04), thrombomodulin (3.67±2.8 vs 1.1±0.53 pg/ml, p<0.004) were greater than in the controls, whilst NID (8.67±2.2 vs 14.5±3.2%, p<0.001) and FMD (4.73±1.9 vs 8.4±1.9%, p<0.001) parameters were lower than in the controls. IMT was higher in the study group (0.69±0.12 vs 0.59±0.1 mm, p<0.04). There was a significant and remarkable correlation between body weight and NID (r = -0.69, p<0.04) as well as FMD (r = -0.7; p<0.04) in the obese subjects, but a positive one with IMT (r=0.48; p<0.04). Glucose at 60 and 120 min of OGTT inversely correlated with NID (r = -0.51 and r= -0,54; respectively, p<0,04) and FMD (r= -0,76 and r= -0.63; p<0.04), also plasma insulin at 60 and 120 min showed the same relationship with NID (r = -0.56 and r= -0.45; respectively, p<0.04) and FMD (r= -0.76 and r= -0.51; respectively, p<0.04). There were no differences between both groups in regard to plasma lipid profile, systolic and diastolic blood pressure.
Conclusion: Non-diabetes morbidly obese subjects already present with mild post-challenge hyperglycemia and hyperinsulinemia as well as endothelial dysfunction and sucblinical inflammation. The results of our study suggest that vascular injury associated with obesity precedes diabetes development. This finding might have important implications for adopting prevention measures of cardiovascular disease in morbidly obese individuals.

Brown fat lipoatrophy with age is sufficient to induce obesity, vascular dysfunction and vascular insulin resistance
Y.F. Otero[1,2], A. Gomez-Hernandez[1,2], N. de las Heras[3,4], O. Escribano[1,2], V. Cachofeiro[3,4], V. Lahera[3,4], M. Benito[1,2];
[1]Biochemistry and Molecular Biology, School of Pharmacy, Madrid, [2]CIBERDEM, Barcelona, [3]Physiology, School of Medicine, Madrid, [4]RECAVA, Madrid, Spain.

Background and aims: Recently, it has been described that functional brown adipose tissue (BAT) is prevalent in adult humans and has a protector role against obesity in older patients. Our aim was to study glucose metabolism and vascular alterations in BAT insulin receptor knockout mice (BATIRKO), a mouse model characterized by a conditional-dependent loss of interscapular brown fat and an insulin secretion defect.
Material and methods: In the present work, we have analyzed vascular function, vascular insulin signaling and the expression of genes involved in vascular alterations in the aorta artery from 33- and 52-weeks old Control and BATIRKO mice.
Results: BATIRKO mice at 52 weeks had a significant decrease of BAT mass, as well as a significant increase of body weight, visceral WAT mass and TNF-α and leptin circulating levels. High circulating levels of these cytoadipokines are due to a significant increase of their expression by BAT and WAT. In addition, BATIRKO mice at 52 weeks showed more severe glucose intolerance and mild fasted hyperglycemia as compared with BATIRKO mice at 33 weeks. This fact is owing to an insulin secretion defect. We have also observed a significantly reduction of endothelium-dependent relaxation induced by acetylcholine in aortic rings from BATIRKO mice at 52 weeks-old as compared with at 33 weeks-old BATIRKO mice. In contrast, endothelium-independent relaxations to sodium nitroprusside were comparable in all groups. In addition to endothelial dysfunction, we observed a higher constrictor response to angiotensin II in aortic rings in 52 weeks BATIRKO mice as compared with all other groups studied. In addition, we observed a significant increase of genes markers of vascular dysfunction (ET-1 and ICAM-1) and inflammation (MCP-1, iNOS, TNF-α, TNFRs and PAI-1) in the aorta artery from 52 weeks BATIRKO mice as compared with all other groups studied. Finally, we analyzed vascular insulin resistance as vasorelaxing response to insulin in phenylephrine pre-contracted rings. A significant decrease trend of relaxing response to insulin in aortic rings was observed in 52 weeks BATIRKO mice versus all other groups studied. Concurrently, insulin signaling was dramatically impaired in aorta artery from BATIRKO mice at 52 weeks as revealed the lack of phosphorylation of AKT (Ser473) and eNOS (Ser1177) as compared with all other groups.

Conclusion: Our results demonstrate that the lack of brown fat tissue mass during aging is sufficient to induce obesity, glucose intolerance, vascular dysfunction and vascular insulin resistance without an overall insulin resistance.

Microvascular reactivity and oxidative stress after standard breakfast in patients with recently diagnosed type 2 diabetes
E. Horova, M. Prazny, J. Škrha;
3rd Department of Internal Medicine, 1st Faculty of Medicine, Charles University, Prague, Czech Republic.

Background and aims: The aim of the study was to compare skin microvascular reactivity (MVR) with oxidative stress and metabolic parameters at fasting status and postprandially in patients with recently diagnosed Type 2 diabetes.
Materials and methods: Twenty patients with Type 2 diabetes (mean age 58±6 years, HbA_{1C} 4.8±0.5%, diabetes duration 2.3±1.3 years, metformin treatment only) were included in the study. Blood samples were taken before and after 60, 120 and 180 minutes after standard breakfast. MVR was measured before and after 60 and 180 minutes. Standard breakfast consisted of one roll (40 g), jam (20 g), butter (10 g) and 200 ml of defined supplemental nutrition Resource (in total 2006 kJ, proteins 22.36 g, carbohydrates 62.94 g, fat 15.51 g). Skin MVR was measured by the laser Doppler flowmetry during post-occlusive (PORH) and thermal hyperemia (TH). Glycemia, insulinemia and β-hydroxybutyrate (BHB) concentration were evaluated and malonyldialdehyde (MDA) and conjugated dienes (CD) were used for the estimation of oxidative stress.
Results: Blood glucose increased from baseline 6.9±0.6 mmol/l up to 8.0±1.6 mmol/l after 60 minutes and 7.6±1.2 mmol/l ($p<0.01$) after 120 minutes in the postprandial phase. Glycemia consequently decreased after 120 minutes down to baseline level (6.2 ± 0.8 mmol/l). Insulinemia increased significantly (baseline, 60, 120, 180 minutes, respectively: 39±16 - 142±82 - 106±63 - 55±39 mIU/l, $p<0.01$) while BHB decreased (0.24±0.16 - 0.16±0.06 - 0.15±0.07 - 0.16±0.06 mmol/l, $p<0.01$). MDA concentration was significantly lower after 120 minutes than at baseline (3.02±0.48 vs. 2.80±0.40 µmol/l, $p<0.05$). Changes of several parameters of MVR were detected: maximal perfusion during PORH decreased after 180 minutes compared to baseline (235±66 vs. 198±53 PU, $p<0.01$), although maximal perfusion (expressed in % of baseline perfusion) during PORH increased after 60 and 180 minutes (baseline, 60, 120 minutes, respectively: 165±46 - 237±211 - 273±194 %, $p<0.05$). Significant decrease was found in maximal perfusion during TH after 180 minutes compared to baseline (113±53 vs. 145±71 PU, $p<0.05$). Negative correlation was found between fasting glycemia and maximal perfusion during PORH ($r=-0.51$, $p<0.05$) and positive correlation was observed between the concentration of CD and velocity of perfusion increase during TH ($r=0.63$, $p<0.01$). Positive correlation was found also between fasting concentration of CD and MDA ($r=0.53$, $p<0.05$) as well as between maximal perfusion during PORH and insulinemia after 60 minutes ($r=0.65$, $p<0.01$). Statistically significant positive relation was found between blood glucose and insulin after 180 minutes ($r=0.90$, $p<0.001$) as well as between CD concentration and time to maximal perfusion during TH at the same time ($r=0.59$, $p<0.01$).
Conclusion: Significant metabolic changes were observed postprandially in patient with early stage of Type 2 diabetes in this study. In accordance with other studies, microvascular reactivity was probably mostly influenced by increased insulinemia and vasodilatory effect of insulin. Moreover, MVR may also be modulated by the oxidative stress. The relationship between MVR and insulinemia may imply that the B-cell dysfunction can consequently lead to microvascular dysfunction through the effect of insulin. However, to confirm this hypothesis, further research in this field is necessary.

1310

Reduced number of early circulating vascular progenitor cells and increased central arterial stiffness in polycystic ovary syndrome
J. Karalliedde, M. Reza, G. Sivakumar, C. Dessapt, L. Gnudi;
Cardiovascular Division, King's College London, United Kingdom.

Background and aims: Subjects with Polycystic ovarian syndrome (PCOS) are at risk of type 2 diabetes and associated cardiovascular disease. The mechanism of this enhanced risk is unclear. The number and function of circulating vascular progenitor cells (VPC) and arterial stiffness are independent predictors of cardio-metabolic risk. Aim: To study the number and function of VPC and arterial stiffness in non-obese PCOS subjects as compared to age and body mass index (BMI) matched healthy controls.
Materials and methods: Subjects with a confirmed diagnosis of PCOS with BMI<30 (n=17) attending a University hospital outpatient clinic and healthy controls (n=12) were studied. VPC number was measured by fluorescence activated cell sorting. VPC function was assesed in vitro by tube formation and VPC migration assay. Augmentation index (AIx) a measure of central arterial stiffness and central aortic blood pressures were measured by applanation tonometry at the radial artery.
Results: There was no statistically significant differences between the PCOS vs. control group in, mean ± SEM, age (26.4±1.0vs. 23.2±1.5 yrs), weight (61.0± 1.2 vs. 65.9±3.1 kg), BMI (24.2± 0.8 vs. 23.0± 0.7 kg/m^2 $p=0.26$) and waist circumference (86.3± 2.5 vs. 82.1± 1.8 cm) $p>0.05$ for all. Brachial systolic blood pressure, mean arterial pressure and pulse pressures were similar between the two groups. Compared to controls subjects with PCOS had higher central SBP (103.7±2.4 vs. 94.9± 2.2 mmHg $p=0.01$), central DBP (75.6±1.8 vs. 69.7±2.4 mmHg $p=0.06$) and central pulse pressure (28.2±1.0 vs. 25.1±1.1 $p=0.04$). AIx was significantly, more than 3 fold, higher in PCOS subjects compared to control (18.4±1.9 vs. 4.9± 2.0 $p<0.0001$). Subjects with PCOS had reduced a significantly reduced number of the early VPC CD34+133+ , mean ±SEM, 328.1± 47.9 vs. 591.0±120.5 $p=0.02$. Other putative VPC (CD34+KDR+, CD34+133+KDR+) were not statisically different between groups. VPC function was not impaired in PCOS as compared to healthy controls. CD34+133+ VPC number and AIx was not correlated.
Conclusion: Non obese PCOS is characterized by reduced numbers of early VPC but preserved function. PCOS subjects have increased central arterial stiffness. These two unrelated changes may explain the enhanced cardio-metabolic risk of this population.

1311

Hypertension and neuropathy are the main determinants of impaired total arterial compliance in type 2 diabetic patients
M. Nguyen[1], E. Cosson[1], I. Pham[2], A. Nitenberg[2], P. Valensi[1];
[1]Endocrinology-Diabetology-Nutrition, [2]Department of Physiology, Jean Verdier Hospital, Bondy, France.

Background and aims: Total arterial compliance (TAC) of the systemic arterial tree may be estimated by left ventricle stroke volume index/ pulse pressure ratio (i.e. a substitute for volume changes of the arterial system/ an index of arterial stiffness). This ratio has been validated against invasive measurements of arterial compliance. A low TAC level has been associated with an increased risk of subsequent cardiovascular events in hypertensive patients and in elderly men. TAC has not yet been evaluated in the diabetic population, in particular as regards to cardiac ischemic disease. Objective was to examine the determinants of TAC in asymptomatic high-risk diabetic patients with known cardiac ischemic status.
Materials and methods: We included 287 asymptomatic patients, 166 men, 59±8 years, with diabetes duration 13±7 years, with at least one additional risk factor (hypertension 73%, dyslipidemia 70%, smokers 22%, nephropathy 38%) and without heart failure. All of them were prospectively screened for silent myocardial ischemia (SMI), defined as an abnormal stress myocardial scintigraphy. TAC was calculated using echocardiographic left ventricle measurements and brachial blood pressure measurement. Cardiac autonomic neuropathy (CAN) was assessed using standard tests (deep-breathing, lying-to-standing and Valsalva).
Results: Mean TAC was 0.68±0.23 ml/m^2/mmHg. Lower TAC levels were associated with higher age ($p=0.006$), body mass index ($p=0.03$), diabetes duration ($p=0.04$) and LDL cholesterol ($p=0.004$), and with peripheral neuropathy ($p=0.001$) and hypertension ($p<0.001$), respectively), but neither with SMI nor CAN. In multivariate analysis including all the significant correlates, hypertension (OR 2.5 [1.2-5.0], $p<0.01$) and peripheral neuropathy (OR 2.2 [1.3-3.7], $p=0.004$) were independent predictors of TAC <0.56 (first tertile). In addition left ventricle stroke volume index was lower ($p=0.02$) and pulse pressure higher ($p<0.01$) in patients with than in patients free of peripheral neuropathy.
Conclusion: In high-risk but asymptomatic type 2 diabetic patients, hypertension and peripheral neuropathy are the main determinants of a reduced TAC. Peripheral neuropathy might contribute to impair TAC by altering vessel tone and vasomotion and increasing blood volume.

Involvement of p66Shc in TNF-alpha-induced endothelial dysfunction

M.R. Orlando, L. Laviola, F. Tortosa, M. Incalza, A. Leonardini, M. Melchiorre, R. Labarbuta, S. Perrini, A. Natalicchio, F. Giorgino;
Endocrinology & Metabolic Diseases, D.E.T.O., University of Bari, Italy.

Background and aims: The pro-inflammatory cytokine TNF-alpha impairs endothelial function by modulating gene expression and increasing intracellular reactive oxygen species (ROS). The p66Shc isoform has been proposed as a sensor of cellular oxidative stress, through its phosphorylation on Ser36, and mediates stress signals in multiple cell types. The aim of our study was to investigate the role of p66Shc in TNF-alpha action in human umbilical vein endothelial cells (HUVEC).
Materials and methods: Expression and phosphorylation levels of specific signaling molecules were assessed by immunoblotting techniques. Intracellular ROS generation, in the presence of the DHE probe, was evaluated by fluorimetric analysis. Gene expression was evaluated by quantitative RT-PCR (qRT-PCR). Wild-type p66Shc and mutant p66Shc, in which Ser36 had been replaced by Ala (p66Shc-Ala36), were selectively overexpressed following infection with recombinant adenoviruses.
Results: Exposure of HUVEC to TNF-alpha (10-50 ng/ml) resulted in increased E-Selectin and IL-8 mRNA levels ($p<0.05$), evaluated by qRT-PCR, and in increased intracellular ROS concentrations ($p<0.05$), assessed by fluorimetry. Treatment with TNF-alpha was also associated with increased phosphorylation of the stress kinase JNK-1/2 ($p<0.05$ at 30 min), of ERK 1/2 ($p<0.05$ at 30 min), and of p66Shc on Ser36 ($p<0.05$ at 30 min). Pre-incubation of HUVEC with the JNK inhibitor SP600125 prevented JNK activation by TNF-alpha and the effect of this cytokine on E-Selectin mRNA ($p<0.05$ vs TNF-alpha alone), but not that on IL-8 gene expression, and also reverted TNF-alpha-induced p66Shc phosphorylation on Ser36 and ROS generation. By contrast, treatment of HUVEC with the ERK inhibitor PD98059 blocked TNF-alpha-induced ROS production ($p<0.05$ vs TNF-alpha alone), but had no effects on E-Selectin gene expression and p66Shc phosphorylation on Ser36. We next obtained a selective 3-fold overexpression of p66Shc in HUVEC by adenoviral transfer (HUVEC/p66Shc). HUVEC/p66Shc showed increased p66Shc Ser36 phosphorylation both under basal conditions and following exposure to TNF-alpha ($p<0.05$ vs controls). This was associated with an increase in E-Selectin mRNA and ROS levels, both basally and after TNF-alpha exposure ($p<0.05$ vs controls). Pretreatment of HUVEC/p66Shc with the JNK inhibitor SP600125 significantly reduced the induction of E-Selectin mRNA levels and ROS synthesis following TNF-alpha ($p<0.05$). In addition, pretreatment of HUVEC/p66Shc with the ERK inhibitor PD98059 prevented TNF-alpha-induced ROS generation ($p<0.05$), but did not modify p66Shc phosphorylation on Ser36. Conversely, overexpression of a phosphorylation-defective p66Shc protein, in which Ser36 had been mutated to Ala, did not augment E-Selectin mRNA and ROS levels beyond those found in wild-type cells.
Conclusion: p66Shc acts as a novel signaling intermediate in the TNF-alpha-MAPK pathways mediating endothelial cell dysfunction, and its action requires p66Shc phosphorylation at Ser36.

Liraglutide down regulates endoplasmic reticulum stress in human endothelial cells exposed to hyperglycaemia

B. Schisano[1], G. Tripathi[1], A.L. Harte[1], P.G. McTernan[1], L. Knusden[2], A. Ceriello[3];
[1]CSRI, University of Warwick, Coventry, United Kingdom, [2]Novo Nordisk A/S, Copenhagen, Denmark, [3]IDIBAPS, Barcelona, Spain.

Background: The endoplasmic reticulum (ER) is a key organelle where membrane and secreted proteins fold into their tertiary and quaternary structure. The ER stress occurs when there is an accumulation of unfolded/misfolded proteins due to disruption of ER homeostasis. The accumulation of unfolded proteins results in the activation of the unfolded protein response (UPR) which is regulated by proteins such as IRE1α, PERK and ATF6. ER stress increases PERK activity, which phosphorylates eIF2α to reduce protein translation. ER contains molecular chaperone proteins including PDI, calnexin, Ero1-Lα and Grp78/BiP and others that promote oxidative protein folding. Data on pancreatic beta cells function indicate that augmented ER stress together with reduced insulin signalling both occur before the onset of frank diabetes. It has also been observed that ER stress may play a causative role in diabetic atherogenesis. Also recent data in mice suggests that hyperglycaemia increases intracellular ER stress, prior to the onset of atherosclerosis. Liraglutide is a GLP-1 analogue that has been proven to enhance insulin signalling and reduce apoptosis in pancreatic beta cells. Investigating its effectiveness in reducing ER stress levels in endothelium might be of great use to determine its capacity in ameliorating not only the pancreatic function and insulin sensitivity, but also prevent atherogenesis and thus cardiovascular complications in diabetics.
Materials and methods: Confluent human vascular endothelial cells (HUVECs) were exposed to a 15mM high glucose media with (HGL) or without (HG) 100nM of liraglutide. Controls were kept in a 5mM normal glucose media with (NGL) or without (NG) 100nM liraglutide with 10mM of mannitol for osmotic balance. After 12 hours of exposure to the hyperglycaemic media, proteins from all the conditions were extracted. Protein analysis was conducted by western blotting.
Results: HuVEC cells exposed to hg media lead to a significant ($*p<0.01$) up regulation of all the ER stress markers as detailed: PDI, calnexin, BiP, Ero1-Lα, IRE1, phospho-eIF2α, compared to cells treated with ng. However in cells exposed to hg and liraglutide there was a significant reduction in ER stress protein expression levels compared to hg alone (PDI, BiP, Ero1-Lα, IRE1, phospho-eIF2α: $p<0.01$; calnexin, $p<0.05$) in HUVEC cells treated with and high glucose. Liraglutide had no additional effects on the basal expression of ER stress markers in normal glucose compared to control.
Conclusion: Our *in vitro* data demonstrates that liraglutide significantly down-regulates ER stress markers in endothelial cells exposed to high glucose levels. This study indicates that liraglutide has additional beneficial effects to reduce ER stress and may support prevention of atherogenesis and thus cardiovascular complications in diabetic patients.

Tissue kallikrein is essential for invasive capacity of circulating proangiogenic cells

G. Spinetti[1], O. Fortunato[1], D. Cordella[1], P. Portararo[1], N. Kraenkel[2], G. Sala-Newby[2], G. Tonolo[3], S. Cherchi[3], C. Emanueli[2], P. Madeddu[2];
[1]IRCCS MultiMedica, Milan, Italy, [2]University of Bristol, United Kingdom, [3]OC San Giovanni di Dio, Olbia, Italy.

Background and aims: The function of circulating proangiogenic cells (PACs) is altered in diabetes and inversely correlated with severity of vascular complications, but underpinning mechanisms remain unclear. We investigated the possibility that components of the kallikrein-kinin system, which are constitutively expressed in human PACs, may be downregulated in diabetes thus contributing to reduced PAC motility and invasiveness.
Materials and methods: Type 2 diabetic patients (T2D, n=22) and age- and gender-matched healthy subjects (n=16) were studied. Circulating mononuclear cells (MNCs) and culture-selected PACs were analyzed for expression of human tissue kallikrein (hK1) and kinin B2 receptor (B_2R) by Q-RT-PCR, western blotting, immunofluorescence staining, and flow cytometry. Secretion of hK1 by PACs was determined by measuring hK1 levels in conditioned media by ELISA and enzymatic activity assay. Moreover, the functional role of the hK1/B_2R duo was assayed by analyzing *in vitro* cellular invasive potential (modified Boyden chambers assay), proangiogenic action (matrigel assay) and activation of matrix metalloproteinase-2 (MMP2, in situ- and gelzymography) in the presence or absence of hK1 silencing by siRNA, B_2R antagonism by icatibant or MMP inhibition by GM6001. The activity of Akt was assayed as a measure of B_2R coupling to its downstream signaling machinery. Adenovirus-mediated gene transfer of hK1 (*Ad.hK1*) and B_2R (*Ad.B_2R*) was used to rescue the impaired T2D PACs phenotype.
Results: The two groups did not differ in smoking habit and LDL levels. T2D patients had higher BMI (30.2 ± 6.4 vs. 25.2 ± 3.5% in healthy) and Hba1c levels ranging between 5 and 7.5 (average value 6.6 ± 0.8), all patients were on diabetic diet, 18 out 22 were on metformin therapy. MNCs and culture-selected PACs from healthy subjects express and release mature hK1 protein. HK1 gene silencing impaired migration/invasion and proangiogenic capacities and reduced MMP2 activity in healthy PACs. T2D PACs showed reduced invasion and proangiogenic potential (-1.8 and 2.0 fold vs. controls, $p<0.05$) and lower hK1 protein (-56.6 %, $p<0.05$), but normal hK1 mRNA abundance, pointing at a post-transcriptional defect. Furthermore, T2D-PACs expressed normal levels of B_2R, but the receptor was not conductive as verified by re-

duced Akt activity following kinin stimulation. *Ad.hK1* increased the migratory (1.6 fold) and invasive (1.8 fold) activity of healthy PACs, and stimulated their capacity to promote angiogenesis on matrigel (1.4 fold) ($p<0.05$ vs. *Ad.Null*, for all comparisons). Inhibitory experiments ascribed the effects of hK1 overexpression to B_2R- and MMP-dependent mechanisms. Importantly, *Ad.hK1* was unable to rescue the impaired invasion capacity of T2D-PACs and combined genetic engineering with *hK1* and B_2R was necessary to correct the diabetic phenotype.
Conclusion: Human PACs bear active hK1, which cooperates with B_2R and MMP2 for invasion. T2D-induced deficit of hK1 results in PACs dysfunction. In diabetes, different components of the kallikrein-kinin system need to be overexpressed to restore proper invasiveness. This study unravels new molecular mechanisms underpinning PACs dysfunction in T2D.

Exendin-4, GLP-1(7-36) and GLP-1(9-36) stimulate proliferation of human coronary artery endothelial cells through PKA- and PI3K/Akt/ eNOS-dependent pathways
Ö. Erdogdu[1], D. Nathanson[2], Å. Sjöholm[2], T. Nyström[2], Q. Zhang[1];
[1]Department of Clinical Science and Education, [2]Department of Internal Medicine, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden.

Background and aims: We recently showed that the glucagon-like peptide-1 (GLP-1) receptor is expressed in human coronary artery endothelial cells (HCAECs) and that GLP-1 improves endothelial dysfunction in type 2 diabetic patients with coronary artery disease. Exendin-4 is a stable GLP-1 receptor agonist and has been approved for clinical use against type 2 diabetes. In contrast to their glycemic effects, the role of GLP-1 and its analogues on endothelial regeneration is not known. The aim of the present study was to investigate the effects of exendin-4, GLP-1(7-36) and GLP-1(9-36) on cell proliferation in HCAECs *in vitro.*
Materials and methods: HCAECs were treated with exendin-4 (1-10 nM), GLP-1 (7-36) (100 nM) or the major GLP-1 metabolite GLP-1 (9-36) (100 nM), respectively, in serum-deficient medium in the presence of 5 mM glucose for 48 h. Phosphorylation and expression of the endothelial nitric oxide synthase (eNOS), Akt and MAP kinase were examined by Western blotting using anti-phospho-eNOS (Ser1177), anti-eNOS, anti-phospho-Akt (Ser 473), anti-Akt, and anti-phospho-MAPK ½ antibodies, respectively. ^{3}H-thymidine incorporation was assayed in 96-well plates as a measure of DNA synthesis after 48 h incubation.
Results: Incubation of HCAECs with exendin-4 for 48 h resulted in a dose-dependent increase in DNA synthesis; subsequent neogenesis was confirmed by an increased cell number. Exendin-4 dose-dependently enhanced phosphorylation of eNOS after a 48 h-incubation. The exendin-4-induced activation of eNOS was associated with an increased NO production. In addition, incubation of HCAECs with exendin-4 resulted in an increased Akt phosphorylation, The exendin-4-stimulated activation of eNOS and Akt was prevented after treatment of the cells with Rp-cAMP[S], LY294002, Akt inhibitor IV or L-NAME, the specific inhibitor for PKA, the phosphoinositide 3-kinase (PI3K), Akt and eNOS, respectively. Subsequently, the exendin-4-induced proliferation was abolished. Incubation of HCAECs with exendin-4 also caused activation of MAP kinase. However, suppressing MAP kinase activity did not affect exendin-4-induced cell proliferation. The effects of exendin-4 on enzyme activation and cell proliferation were mimicked by GLP-1(7-36) and GLP-1(9-36), but blocked by the GLP-1 receptor antagonist exendin (9-39). Co-incubation of exendin-4 with GLP-1(7-36) did not produce additive effects.
Conclusion: Our results indicate that exendin-4, GLP-1(7-36) and GLP-1(9-36) stimulate proliferation of HCAECs by PKA and PI3K/Akt/ eNOS dependent pathways. Proliferation of endothelial cells is involved in endothelial repair (arterial healing) and angiogenesis, a powerful mechanism to ensure blood supply to tissue at risk if a main artery is chronically occluded. These beneficial effects of exendin-4, GLP-1(7-36) and GLP-1(9-36) on human coronary artery endothelial cells may add yet another salutary non-glycemic property to incretin-based antidiabetic therapy, increasing its clinical utility in type 2 diabetic patients in whom endothelial dysfunction is a salient feature that adversely affect their survival.

The role of osteopontin in endothelial progenitor cell function
E.E. Vaughan[1], A. Duffy[2], T. O'Brien[1];
[1]REMEDI, NUI Galway, [2]Medtronic Inc, Galway, Ireland.

Background and aims: We, and others, have shown that endothelial progenitor cells (EPCs) obtained from patients with diabetes are dysfunctional. We previously identified the angiogenic protein osteopontin (OPN) as being down regulated in diabetic EPCs and furthermore we determined that OPN deficient mice do not recover as well as wild-type mice from hindlimb ischemia. Thus, we hypothesized that OPN may play a critical role in the angiogenic response mediated by EPCs. We aimed to establish the role OPN plays in EPC function and to determine if exposure to OPN could restore the function of OPN knockout EPCs in vivo.
Materials and methods: EPCs were obtained from OPN knockout mice as well as wild-type controls and cultured for 7 days followed by use in a matrigel tubule formation assay. Conditioned media from these cells was also used in the tubule formation assay as well as in a protein array. OPN knockout EPCs or knockout EPCs incubated with recombinant OPN were injected into the ischemic hindlimb of OPN knockout mice and laser Doppler blood flow analysis was performed immediately following surgery as well as at days 7 and 14.
Results: To elucidate the role of OPN in EPCs, a matirgel tubule assay was used to assess in vitro angiogenic potential. KO EPCs induced significantly less tubule formation than WT EPC ($p<.05$, n=3). However, knockout EPCs that were pre-incubated with recombinant OPN induced tubule formation at levels similar to WT and significantly higher than KO cells that were not incubated with OPN ($p<.05$, n=3). Further, conditioned media (CM) from WT cells induced tubule formation to the same levels as the EPCs themselves suggesting that secreted proteins are responsible for angiogenic effect. Interestingly, when KO EPC were pre-incubated with OPN, the CM media induced tubule formation to WT levels(n=3), even though there was no OPN directly in the media. Hence, we further hypothesized that OPN is acting on EPC to induce the secretion of angiogenic cytokines. Thus a protein-array was performed on EPC from WT, KO and KO EPCs exposed to OPN. WT EPCs expressed FGFα at a much higher level than KO cells. Further, WT cells expressed Il-6 and TGF-α whereas KO cells did not express these proteins at detectable levels. Interestingly, when KO cells are exposed to OPN these proteins are expressed at WT levels. Additionaly, we demonstrated that EPCs from humans and diabetic rabbits incubated with OPN had increased angiogenic potential in a tubule assay ($p<.05$ n=3) further suggesting that OPN plays a critical role n EPC funtion. When OPN KO EPCs were injected into the ischemic hindlimb of OPN KO mice blood flow to the limb was improved significantly at days 7 ($p<.05$ n=6) and 14 ($p<.01$).
Conclusion: Taken together, this data suggests that the decreased OPN expression in diabetic EPCs may contribute to their dysfunction. We propose that OPN increases the angiogenic potential of EPCs via an autocrine mechanism whereby OPN is secreted by the EPC and subsequently induces the expression of a variety of angiogenic proteins. Futher, we have demonstrated that incubation of OPN deficent EPCs with recombinant OPN is sufficent to restore function of the EPCs even when returned to an in vivo setting.

Impaired ischaemia-induced angiogenesis in diabetic mice depends on glycaemic variability
D. Pitocco, F. Zaccardi, F. Biscetti, G. Straface, P. Rizzo, T. Musella, A. Flex, S. Caputo, G. Ghirlanda;
Internal Medicine, Catholic University, Rome, Italy.

Background and aims: Glycemic variability (GV) is an adjunctive risk factor for diabetic vascular complications. However, neither a cause-effect correlation between glucose instability and vascular dysfunction, nor the molecular bases of such a dysfunction have been investigated previously. The aim of this study was to investigate the role of GV in diabetic vascular complications and to explore the molecular pathways modulated by glycemic "swings".
Materials and methods: Diabetes was first induced by streptozocin in 60 mice. Then 30 diabetic mice received basal insulin administration once daily plus two oral boluses of glucose solution (variable group, VG) and another 30 mice received basal insulin once daily plus two oral boluses of saline solution (stable group,SC) for a period of 30 days. Glycemia was measured eight times daily to detect GV. Post-ischemic neovascularization, induced by hindlimb

ischemia 30 days after diabetes onset, was studied and compared in VG, SC and untreated groups.
Results: Indices of GV were significantly different between VG and SG groups, whereas there was no significant difference in the mean glycemic values. Laser Doppler perfusion imaging revealed that the mean blood flow of control mice reached 94% of the pre-ischemic flow 28 days after hindlimb surgery. Perfusion recovery was significantly attenuated in SC mice compared to control mice 7, 14, 21 and 28 days after surgery. Interestingly, recovery was significantly impaired in VG compared to the SG 7, 14, 21 and 28 days after ischemic injury. Histological analysis revealed a higher increase in the capillary density of ischemic limbs in SG respect to the VG. Immunostaining and western blot analysis revealed that the impaired angiogenic response in VG occurred in association with reduced VEGF production and decreased eNOS and Akt phosphorylation.
Conclusion: This is the first murine model of GV. Our data indicate that GV causes a significant impairment of ischemia-induced angiogenesis in diabetes, regardless of average blood glucose levels, and that this impaired collateral vessel formation depends on an altered VEGF pathway. These findings provide new information to understand the biological and clinical effects of GV.

Overexpression of glyoxalase-I improves vascular function in a rat model of diabetes

O. Brouwers[1], P.M.G. Niessen[1], T. Miyata[2], T. Teerlink[3], B.J. Janssen[4], J.G.R. De Mey[4], C.D.A. Stehouwer[1], C.G. Schalkwijk[1];
[1]Internal Medicine, Maastricht University, Netherlands, [2]Centre of Translational and Advanced Research, Tohoku University, Sendai, Japan, [3]Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands, [4]Pharmacology & Toxicology, Maastricht University, Netherlands.

Background and aims: The reactive advanced glycation endproduct (AGE) precursor methylglyoxal (MGO) and MGO-derived AGEs are associated with diabetic vascular complications. In this study glyoxalase-I (GLO-I) transgenic rats were used to explore whether overexpression of this MGO-detoxifying enzyme reduces levels of AGEs, and thereby improves cardiovascular function in a rat model of diabetes.
Materials and methods: Diabetes was induced in wild type (WT) and GLO-I overexpressing animals by a single tail vein injection with streptozotocin (STZ). After 12 and 24 weeks of diabetes, before termination, cardiac function was monitored by ultrasound and mean arterial blood pressure was measured intra-arterially, under isoflurane anaesthesia. After termination, vascular function of isolated mesenteric resistance arteries (MrA) was assessed by wire myography. Blood was drawn and multiple tissues were collected for further analysis. Circulating levels of glyoxal (GO), MGO, 3-deoxyglucosone (3-DG), and the AGEs Nε-(1-carboxymethyl)lysine, Nε-(1-carboxyethyl)lysine and hydroimidazolone, were assessed by high performance liquid chromatography with fluorescence or tandem mass spectrometry detection. Gene-expression levels of vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule 1 (ICAM-1) in MrA were measured by real time PCR.
Results: GLO-I activity was significantly elevated in multiple tissues of all transgenic rats. STZ treatment resulted in a fivefold increase of blood glucose concentrations irrespective of GLO-I overexpression. Levels of GO, MGO, 3-DG and AGEs were elevated in the diabetic WT rats ($p<0.01$). In diabetic GLO-I rats, GO and MGO were significantly decreased by 80 % ($p<0.05$), and plasma AGEs by 50% ($p<0.05$). In WT rats, STZ treatment significantly decreased mean arterial pressure (91±2 vs. 59±3 mmHg; $p<0.01$) and cardiac output (108±12 vs. 81±7 mL/min; $p<0.05$). GLO-I overexpression in diabetic rats significantly blunted the fall in mean arterial blood pressure (76±7 3 mmHg; $p<0.05$ compared with WT diabetic rats) without affecting the cardiac output response following administration of STZ (80±7 mL/min). In isolated MrA, STZ treatment significantly attenuated potassium-induced contractions and endothelium-dependent relaxations ($p<0.05$). These consequences of diabetes were significantly reduced by GLO-I overexpression ($p<0.05$). Furthermore, the increased mRNA levels of VCAM-1 and ICAM-1 in the MrA of the diabetic WT rats were normalised by GLO-I overexpression.
Conclusion: This study shows that overexpression of GLO-I detoxifies (methyl)glyoxal and thereby decreases (M)GO-derived AGEs in diabetic rats. The fact that GLO-I overexpression is associated with higher blood pressures and improved vascular function *ex vivo*, but not cardiac function, suggests that GLO-I protects arterial rather than cardiac function after STZ induced diabetes in rats.

The role of MRP8 and MRP14 in in stent restenosis in the diabetic rat

A. Stocca[1], D. O'Toole[2], A. Duffy[3], T. O'Brien[1];
[1]Medicine, REMEDI, [2]Anesthesia, Lung Biology Group, [3]Medtronic, Galway, Ireland.

Background and aims: The prevalence of type 2 diabetes mellitus is reaching pandemic proportions. The most common cause of death in diabetes mellitus is cardiovascular disease. Patients frequently undergo vascular interventions such as stenting, as a therapy for this disorder. While the occurrence of in stent restenosis has been reduced by the use of drug eluting stents, this is less effective in diabetes mellitus than in non-diabetic subjects. In addition, drug eluting stents may impair endothelial recovery post-stenting which may lead to an increased risk of in stent thrombosis, a condition with mortality of approximately 40%. Novel approaches to the prevention of in stent restenosis which do not impair endothelial function are required.
Materials and methods: The Zucker fatty rat has been chosen as model of type 2 diabetes for its metabolic characteristics. Stent implant was performed in fatty rats and lean controls in the left internal carotid artery: the animals were sacrificed before stenting, 3 days and 14 days post surgery. Samples from day 14 were plastic embedded for histomorphometry; unstented carotid arteries and 3 day post surgery arteries have been used for RNA isolation. Rat Aortic Endothelial Cells (RAOEC) were cultured in normal glucose (5.5mM) and high glucose (22mM) for 48hr before performing cell count, apoptosis, proliferation and migration assays.
Results: The Zucker fatty rat demonstrated exaggerated intimal hyperplasia 14 days post surgery in comparison to lean rats (30% vs 15%). Microarray analysis showed MRP8 and MRP14 mRNAs were upregulated ~8-fold in the carotid artery of the fatty rats versus lean controls. Quantitative PCR confirmed this result. RAOEC incubated in high glucose showed a reduction in the cell number (approx 30%) as a result of increased apoptosis and reduced proliferation. Migration of rat aortic endothelial cells (RAOECs) was impaired (60% reduction) when the cells are exposed to high glucose. Interestingly endothelial cells (ECs) incubated in high glucose displayed a 75-fold upregulation of MRP8 and a 5-fold upregulation of MRP14. MRP8 and MRP14 were cloned and shRNAs designed targetting them: RAOEC overexpressing MRP8 or MRP14 showed similar migration impairment to RAOECs exposed to high glucose; the migratory capacity was partially restored when the high glucose cells were treated with the shRNA against MRP8, but not against MRP14.
Conclusion: We show that MRP8 and MRP14 have an active role in endothelial cell dysfunction in diabetes. MRP8 and MRP14 are overexpressed in the arteries of diabetic rats and its expression is augmented in endothelial cells exposed to high glucose. MRP8 and MRP14 expression reduces the migration of endothelial cells. Endothelial cell proliferation and migration are fundamental to re-endothelialization of implanted stents, and thus limiting restenosis. Blocking MRP8 expression using shRNA we have been able to restore the migrational capacity of endothelial cells inhibited by high glucose incubation. MRP8 could be considered a good target to reduce in stent restenosis in diabetes.

Ablation of vascular endothelial phosphoinositide-dependent protein kinase 1 deteriorates the volume of blood flow in skeletal muscle

K. Tawaramoto[1], M. Hashiramoto[1], K. Kotani[1], W. Ogawa[2], F. Tatsumi[1], S. Hamamoto[1], M. Shimoda[1], Y. Kanda[1], M. Kasuga[3], K. Kaku[1];
[1]Department of Diabetes, Endocrinology and Metabolism, Kawasaki Medical School, Okayama, [2]Department of Internal Medicine, Division of Diabetes, Metabolism and Endocrinology, Kobe University Graduate School of Medicine, Hyogo, [3]Research Institute, International Medical Center of Japan, Tokyo, Japan.

Background and aims: Diabetes mellitus was well-known disorder complicated with lowered angiogenesis and ischemic status especially in heart and skeletal muscle. Regulation of abundant endothelial growth factor with phosphoinositide 3-kinease (PI3K) and phosphoinositide-dependent protein kinase 1 (PDK1)-Akt signal in vascular endothelial cells (ECs) is believed the most important signal during the step of angiogenesis, which might be interfered by hyperglycemia. To evaluate the systemic pathway of angiogenesis under PI3K signal, we generated ECs specific PDK1 knock out mice using Cre-loxP system and investigated the degree of impaired angiogenesis of skeletal muscles under the normo- and hyperglycemia status.

Materials and methods: Mice with PDK1 deficiency in ECs (VEPDK1KO) were obtained by crossing PDK1$^{lox/lox}$ mice with Tie2-Cre PDK1$^{lox/+}$ mice. To obtain diabetic VEPDK1KO, streptozotocin (STZ; 150mg/kg BW, i.p.) was intraperitonealy injected into 2-month-old male mice. After 1 month of injection, blood flow in lower leg-skeletal muscle was evaluated by the non-invasive blood flowmeter (ADVANCE co.).
Results: PDK1 protein levels in ECs were reduced by 80-90 % in VEPDK1KO. The phospholylation of Akt at Thr308 stimulated with insulin or vascular endothelial growth factor (VEGF) was reduced by 58% or 64%, respectively. In STZ-induced diabetic mice, body weight decreased and blood glucose was elevated, though which were similar between both genetics (BW: CON 33.9±1.7, KO 32.2±1.3, STZ-CON 21.5±1.3, STZ-KO 23.6±1.7 g, blood glucose: CON 83.3±7.9, KO 70.0±7.0, STZ-CON 152±15.1, STZ-KO143.4±34.7 mg/dl). In normoglycemic mice, the basal blood flow in lower leg was similar in both groups of mice (CON 4.0±0.9, KO 4.3±2.1 ml/min/100g), but the blood flow stimulated with insulin (10μU/g BW, 10min) was significantly lower in VEPDK1KO mice compared with the control (CON 5.9±1.4, KO 4.0±1.2 ml/min/100g). The phospholylation of eNOS, critical regulator of angiogenesis, at Ser-1177 of skeletal muscle was also decreased in VEPDK1KO by 40%. On the other hand, the basal blood flow readily decreased in diabetic mice (STZ-CON 2.4±0.8, STZ-KO 2.3±0.1 ml/min/100g), and insulin injection did not alter the blood flow in both control and VEPDK1KO mice (STZ-CON 2.2±0.2, STZ-KO 2.2±0.4 ml/min/100g). VEGF expression in skeletal muscles was similar in normoglycemic CON and KO (102 % of CON), but lowerd in diabetic mice (STZ-CON 71%, STZ-KO 68% of CON).
Conclusion: The present results suggest that the PI3K signal of ECs is critical for insulin-induced angiogenic phenomena in normoglycemic status. In diabetic state, however, other pathways related with complicated metabolic disorders might be comprehensively meaningful for angiogenesis in skeletal muscle.

Human C-peptide decreases hyperglycaemia-induced reactive oxygen species (ROS) and activation of apoptotic pathways in human aortic endothelial cell

V. Cifarelli, M. Trucco, P. Luppi;
Pediatrics, University of Pittsburgh Medical School, Pittsburgh, USA.

Background and aim: High glucose is toxic to endothelial cells through stimulation of reactive oxygen species (ROS) and inflammation, which cause cellular stress leading to apoptosis. Our previous studies have shown that C-peptide antagonizes high glucose-induced endothelial dysfunction by displaying a beneficial anti-inflammatory activity directly on endothelial cells. The aim of this study was to investigate whether C-peptide is able to retrieve high glucose-induced vascular damage by reducing the generation of ROS in Human Aortic Endothelial Cells (HAEC). We focused on the possible effect of C-peptide on the assembly of the NAD(P)H oxidase machinery under high glucose conditions. Activation of apoptotic pathways in HAEC was also investigated.
Materials and methods: HAEC were exposed to high glucose (25mmol/L) and Tumor Necrosis Factor-α (TNF-α; 20ng/μl) for 12-48h in presence or absence of physiologic concentrations of either C-peptide (2-10 nM) or scrambled C-peptide as a control. ROS production was determined by using the fluorescent probes 5-(and-6)-carboxy-2',7'-dichlorofluorescein diacetate (carboxy-DCFDA) by Flow Cytometry. Translocation of the NAD(P)H oxidase subunits p47phox and Rac-1 from the cytosol to the plasma membrane was investigated as a prove of the activated enzymatic machinery for ROS generation. Apoptosis was assessed by determination of cytoplasmic histone-associated-DNA-fragments and Caspase-3 activity using ELISA kits. Mitochondrial and cytoplasmic protein extracts were separated and analyzed by Western blotting using anti-Bcl-2, anti-Caspase-3, anti-p47phox and anti-Rac-1 antibodies.
Results:
• High glucose-induced ROS generation is significantly reduced by C-peptide ($p<0.01$) in HAEC to levels detected in normal glucose (see figure below). C-peptide affects translocation of NAD(P)H subunits p47phox and Rac-1 from cytoplasm to plasma membrane.
• C-peptide decreases high glucose-induced apoptosis of HAEC (38% lower vs. control) compared to high glucose alone as shown by reduced DNA fragmentation and Caspase-3 enzymatic activity.
• C-peptide increases Bcl-2 expression (survival gene) in HAEC exposed to high glucose and TNF-α.
Conclusion: Our results indicate that C-peptide at physiologic concentrations reduces high glucose-induced oxidative stress and activates cell survival pathway in endothelial cells. These results strengthen the idea that supplementation of C-peptide in Type 1 diabetic patients might prevent endothelial dysfunction and high glucose-associated vascular complications.

Impaired glucose metabolism and type 2 diabetes are associated with hypercoagulability as determined by thrombin generation in plasma: the role of central obesity and low-grade inflammation. The Hoorn Study

I. Ferreira[1,2], H.J.B. Beijers[3], H.M. Spronk[4], B. Bravenboer[3], J.M. Dekker[5], G. Nijpels[5], H. ten Cate[1,4], C.D.A. Stehouwer[1];
[1]Internal Medicine, Maastricht University Medical Centre, [2]Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, [3]Internal Medicine, Catharina Hospital, Eindhoven, Netherlands, [4]Laboratory for Clinical Thrombosis and Haemostasis, Maastricht University Medical Centre, [5]EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Individuals with type 2 diabetes (DM2) have a greater risk for cardiovascular disease (CVD). A substantial portion of the diabetes-related CVD is due to atherothrombotic events, which could, at least in part, be explained by prothrombotic alterations in these individuals. Recently, a method was developed - the Calibrated Automated Thrombogram (CAT) - to quantitatively measure thrombin generation *in vitro;* in brief, it generates a thrombin generation curve that mimics the overall plasma coagulability potential when a thrombogenic stimulus appears. Prothrombotic alterations in individuals with impaired glucose metabolism (IGM) and DM2 have not been examined before according to this method. We have therefore investigated the extent to which individuals with IGM and/or DM2 had greater levels of thrombin generation than those with normal glucose metabolism (NGM). In addition, we examined whether any such differences were independent of other cardiovascular risk factors, such as smoking, hypertension, dyslipidaemia, (micro)albuminuria, glycemic control and (central) obesity, and/or were mediated by low-grade inflammation (high-sensitivity C-reactive protein - hsCRP).
Materials and methods: We studied 747 individuals (374 women, mean age 68.5±7.1 years) from the Hoorn Study, a population-based cohort study including individuals with NGM (n=276), IGM (n=177) and DM2 (n=294). Thrombin generation in platelet-poor plasma was measured using the CAT method and two parameters were derived: the endogenous thrombin potential (ETP, i.e. area under the thrombin generation curve, which represents the total amount of active thrombin formed after activation of the coagulation cascade) and the peak height of this curve. Data were analyzed with the use of multiple linear regression analyses.
Results: After adjustments for age, sex, prior CVD and smoking status, individuals with IGM or DM2, were characterized by a higher ETP [ß=41.39 nM*min (95%CI: 6.19 to 76.59)] and peak height [ß=8.92 nM (0.12 to 17.71)] as compared with those with NGM (but did not differ from each other with regard to these parameters). These differences were attenuated to ß=2.99 nM (-7.09 to 13.06) and 23.52 nM*min (-16;66 to 63.70), respectively, and were thus no longer significant, when further adjusted for waist circumference and hsCRP. Adjustments for other risk factors did not materially change the differences between groups, however.
Conclusion: Individuals with IGM or DM2 have higher levels of thrombin generation as compared with subjects with NGM and these differences may be explained, to a great extent, by their higher levels of central adiposity and low-grade inflammation.

Body composition as determinant of thrombin generation in plasma. The Hoorn Study

H.J.B. Beijers[1], I. Ferreira[2,3], H.M. Spronk[4], B. Bravenboer[1], J.M. Dekker[5], G. Nijpels[5], H. Ten Cate[2,6], C.D.A. Stehouwer[2];
[1]Internal Medicine, Catharina Hospital Eindhoven, Eindhoven, [2]Internal Medicine and Cardiovascular Research Institute Maastricht, Maastricht University Medical Centre, [3]Clinical Epidemiology and Medical Technology Assessment and Care and PublicHealth Research Institute, Maastricht University Medical Centre, [4]Cardiovascular Research Institute Maastricht and Laboratory for Clinical Thrombosis and Haemostasis, Maastricht University Medical Centre, [5]EMGO Institute for Health and Care Research, VU University Medical Centre, Amsterdam, [6]Laboratory for Clinical Thrombosis and Haemostasis, Maastricht University Medical Centre, Netherlands.

Background and aims: The association between obesity and cardiovascular disease might, at least partially, be explained by a hypercoagulable state. The extent to which body fat mass and its distribution contribute to a hypercoagulable state is unknown. We investigated the association between body composition and thrombin generation, and evaluated the potential mediating role of low-grade inflammation (i.e. high-sensitivity C-reactive protein - hsCRP) herein.
Materials and methods: We studied 588 individuals from the Hoorn Study, a population-based cohort of individuals with normal and impaired glucose metabolism and type 2 diabetes (mean age 69.7 ± 6.5 years, 300 women) in whom total and regional (i.e. trunk, arms and legs) body composition was assessed by whole body dual-energy absorptiometry. Thrombin generation was measured using the Calibrated Automated Thrombogram, a method developed recently which generates a thrombin generation curve that mimics the overall plasma coagulability when a thrombogenic stimulus appears. The area under this curve is the endogenous thrombin potential (ETP) and represents the total amount of active thrombin formed after activation of the coagulation cascade. Data were analyzed with multiple linear regression models in men and women separately. All analyses were adjusted for age, glucose metabolism status and smoking.
Results: Men and women differed with respect to total body fat % (28±7 vs. 42±7), trunk (12.7±5.5 vs. 14.7±5.5) and peripheral (i.e. arms + legs) fat (9.5±2.9 vs.14.9±4.6) and lean (24.9±3.4 vs.17.1±2.4) masses (in kg), but not with respect to ETP (1188±234 vs.1186±204 nM*min, respectively). Total body fat % was positively associated with ETP in women [standardized regression coefficient (ß)=0.20 (95%CI: 0.09 to 0.32)], but not in men [ß=-0.02 (-0.15 to 0.11)]. Detailed analyses of regional body composition in women showed that trunk [ß=0.23 (0.05 to 0.40)], but not peripheral fat mass [ß=-0.02 (-0.18; 0.15)] was associated with greater ETP, and that there was a trend towards an inverse association with peripheral lean mass [ß=-0.12 (-0.25 to 0.01)]. The strength of the positive associations between total and trunk fat and ETP in women did not materially change after further adjustments for blood pressure, dyslipidaemia or microalbuminura, but were attenuated by 35% [to ß=0.13 (0.01 to 0.26)] and 45% [to ß=0.10 (-0.04; 0.23)], respectively, when further adjusted for hsCRP.
Conclusion: Body fat mass, in particular a central pattern of fat distribution, is associated with higher levels of thrombin generation in elderly women, but not in men. This association is partially explained by adiposity-related low-grade inflammation.

Oxidative stress is involved in the inhibitory effects exerted by high glucose on platelet sensitivity to aspirin

G. Anfossi, I. Russo, M. Viretto, L. Mattiello, G. Doronzo, M. Trovati;
Department of Clinical and Biological Sciences, University of Turin, Internal Medicine and Metabolic Disease Unit, San Luigi Gonzaga Hospital, Orbassano, Italy.

Background and aims: According to therapeutic guidelines, the largest majority of type 2 diabetic patients should be treated by aspirin: a high prevalence of aspirin-resistance, however, has been observed in these subjects, inducing to investigate the mechanisms involved. Aspirin reduces platelet function both by decreasing the synthesis of Thromboxane A2 (TXA_2)and by increasing the synthesis on nitric oxide (NO), a powerful physiological anti-aggregating agent. In a recent study carried out in 45 healthy subjects,

we demonstrated that a short-time *in vitro* platelet exposure to high glucose reduces the aspirin anti-aggregating effect by decreasing the aspirin ability to increase NO synthesis, without influencing TXA_2 formation. Aim of this study is to evaluate whether oxidative stress is involved in this intriguing phenomenon.

Materials and methods: The study has been carried out in 8 healthy volunteers (M/F:4/4; age: 24.1±0.9 years; BMI: 22.58±0.4 kg/m^2), non smokers, with normal glucose tolerance and insulin sensitivity. In platelet-rich plasma (PRP) and washed platelets from venous blood samples, we evaluated the influence of a 30-min exposure to lysine acetylsalicylate (LAS: 5-300 micromol/l) on platelet aggregation induced by sodium arachidonate (NaAA; 1 mmol/l) and ADP (20 micromol/l) (Born's method), and on the NO synthesis (conversion of 3H-arginine to 3H-citrulline) without and with a 60 min pre-incubation with 25 mmol/l D-glucose, both in the absence and in the presence of the thiol antioxidant compound amifostine (200 micromol/l) added 20 min before LAS.

Results: High glucose reduced LAS ability to inhibit platelet responses agonists: actually, in PRP, Maximal Aggregation (MA) in response to NaAA was 70.4±2.9 without vs 84.7±2.3 with 25 mmol/l glucose (p<0.002) and MA in response to ADP was 64.5±1.4% without vs 90.1±4.0% with 25 mmol/l glucose (p<0.0001). Platelet exposure to amifostine did not modify platelet responses to agonists, but blunted the inhibitory effects exerted by high glucose on the LAS anti-aggregating action: in the presence of amifostine, MA in response to NaAA was 64.6±1.5 without and 67.1±1.8% with 25 mmol/l glucose (ns), MA in response to ADP was 56.8±2.1 without and 61.8±2.4% with 25 mmol/l glucose (ns). Furthermore, in washed platelets, high glucose inhibited the LAS-induced ability to enhance NO synthesis, which was (pmol/min/mg protein): 0.134±0.019 at baseline, 0.272±0.022 with LAS in the presence of 5 mmol glucose (p<0.001) and 0.127±0.026 with LAS in the presence of 25 mmol/l glucose (ns vs baseline). Washed platelet exposure to amifostine did not modify NO synthesis, but blunted the inhibitory effect exerted by high glucose on LAS-induced NO enhancements: in the presence of amifostine, NO synthesis (pmol/min/mg protein) was 0.142±0.005 at baseline, 0.318±0.02 with LAS in the presence of 5 mmol glucose (p<0.0001 vs baseline) and 0.211±0.013 with LAS in the presence of 25 mmol/l glucose (p<0.0001 vs baseline).

Conclusion: Oxidative stress is involved in the ability of high glucose to reduce the anti-aggregating effect of aspirin by impairing the aspirin-induced increase of NO synthesis. This information explains a potential mechanism involved in the aspirin resistance observed in diabetes.

The platelet-inhibitory effect of low-dose acetylsalicylic acid is dependent on glycaemic control in type 2 diabetes

B.A. Lemkes[1], L. Bahler[1], P.W. Kamphuisen[2], V.E.A. Gerdes[2], A.K. Stroobants[3], E.J. van den Dool[3], R. Nieuwland[3], J.B.L. Hoekstra[1], F. Holleman[1];
[1]Internal Medicine, Academic Medical Centre, [2]Vascular Medicine, Academic Medical Centre, [3]Clinical Chemistry, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: The clinical benefit of low-dose acetylsalicylic acid (ASA) treatment in primary prevention of cardiovascular events in type 2 diabetes (DM2) remains controversial. The platelet response to ASA has been suggested to be diminished in diabetes, but the role of hyperglycaemia has not yet been elucidated. In this study we determined whether (i) the baseline platelet activity and response to ASA differs in patients with DM2 as compared to healthy controls, (ii) glycaemic control influences the platelet response to ASA in DM2 and (iii) higher doses of ASA improve the platelet response in DM2.

Materials and methods: This is a prospective, single-centre, open-label trial. We aim to include 125 subjects and report here the preliminary data for 102 subjects. DM2 patients are categorized by HbA1c value < 7.0% (DC1: n=34), 7.0- 8.5% (DC2: n=33) and > 8.5% (DC3: n=22) and compared to healthy controls (HC: n=13). All subjects underwent three treatment periods, sequentially using 30 mg, 100 mg and 300 mg of ASA for ten days. Laboratory measurements were performed at baseline and following each treatment period. To assess the pharmacological efficacy of ASA, urinary 11-dehydrothromboxane B2 (11dhTxB2) was measured by ELISA. Platelet function was measured by optical platelet aggregation and Verify Now.

Results: Median baseline urinary 11dhTxB2 excretion was 45 pg/mmol (IQR 36-59) in HC, compared to 69 in DC1 (IQR 37-93), 84 in DC2 (IQR 47-101) and 95 in DC3 (IQR 73-143) (p=0.007, ANOVA). Treatment with ASA 30 mg significantly reduced 11dhTxB2 by 62%, 67%, 64% and 68% respectively. Absolute excretion remained significantly different between groups, and followed the same pattern as baseline (p=0.001). Subsequent treatment with 100 mg ASA further reduced 11dhTxB2 in DC2 (p<0.001) and DC3 (p=0.05) Increasing ASA to 300 mg resulted in a further 10% reduction in DC1 (p=0.026).Verify Now showed incomplete suppression of arachodonic acid(AA)-induced platelet aggregation at 30 mg ASA in all DM2 groups when compared to healthy controls (p=0.001). This difference became smaller with ASA 100 mg, with no further changes at 300mg. Interestingly, optical aggregation induced by 1 mmol/L AA was completely suppressed by 30 mg ASA in all groups, but a concentration of 2 mmol/L resulted in an escape from the ASA suppression in DC3.

Conclusion: Our results show that urinary 11dhTxB2 excretion as a measure of platelet activity is increased in DM2 and is highly associated with glycaemic control. ASA 30 mg only partially suppresses platelet activity in DM2, but ASA 100 mg is sufficient for adequate suppression of urinary 11dhTxB2 excretion.

***In vitro* platelet exposure to high glucose reduces the inhibitory effects exerted by chronic aspirin therapy on responses to agonists in non diabetic patients**

I. Russo, C. Frascaroli, L. Mattiello, M. Viretto, G. Doronzo, K. Bonomo, M. Trovati, G. Anfossi;
Department of Clinical and Biological Sciences, University of Turin, Internal Medicine and Metabolic Disease Unit, San Luigi Gonzaga Hospital, Orbassano - Torino, Italy.

Background and aims: We previously observed that "in vitro" incubation with high glucose of platelets from healthy subjects does not modify platelet responses to agonists but reduces the ability of aspirin added "in vitro" to inhibit platelet responses to agonists, suggesting that hyperglycaemia plays a role in the aspirin resistance described in diabetic patients. In the present study we investigated whether "in vitro" exposure of platelets to high glucose influences platelet responses to agonists in non diabetic patients on chronic aspirin treatment.

Materials and methods: We studied 56 non diabetic patients on chronic aspirin therapy (100 mg/day) owing to the presence of severe cardiovascular risk factors and/or previous cardiovascular events: M/F 33/23; age: 60.5±0.82 years; body mass index: 27.7±0.5 kg/m^2. Platelet sensitivity to aspirin was evaluated in platelet-rich plasma (PRP) by determining by Born's method Maximal Aggregation (MA) in response to Sodium Arachidonate (NaAA): patients were defined as "aspirin resistant" when MA in response to NaAA was greater

than 20%. In PRP from both aspirin sensitive and aspirin resistant patients, we evaluated by Borns' method platelet aggregation induced by 1 mmol/l NaAA, 10 µmol/l ADP, 4 µmol/l epinephrine and 4 mg/l Collagen in the presence or in the absence of a 60-min preincubation with high glucose (25 mmol/l).
Results: In aspirin sensitive patients (49/56), PRP incubation with high glucose significantly increased agonist-induced aggregation, being MA in response to NaAA 6.4±0.5% without vs 10.8±0.5% with 25 mmol/l glucose (p<0.0001), MA in response to ADP 67.7±4.8% without vs 77.0±4.7% with 25 mmol/l glucose (p<0.005), MA in response to epinephrine 24.7±3.0% without vs 28.0±4.1% with 25 mmol/l glucose (p<0.05), MA in response to Collagen 29.8±3.8% without vs 36.4±4.8% with 25 mmol/l glucose (p<0.006). The seven aspirin resistant patients presented higher baseline platelet responses to agonist vs the aspirin sensitive-ones: in particular, MA was: 30.4±3.0% vs 6.4±0.5% (p<0.0001) in response to NaAA ; 100.3±5.9% vs 67.7±4.8% (p<0.015) in response to ADP; 48.1±6.9% vs 24.7±3.0% (p<0.007) in response epinephrine; 49.6±2.5% vs 29.8±3.8% (p<0.05) in response to Collagen. In vitro exposure to high glucose of PRP of aspirin resistant patients did not modify responses to agonists, being MA without or with 25 mmol/l glucose 30.4±3.0% and 28.1±4.1% with NaAA (ns); 100.3±5.9% and 98.6±7.9% with ADP (ns); 48.1±6.9% and 46.7±7.6% with epinephrine (ns); 49.6±2.5% and 54.0±9.3% with collagen (ns).
Conclusion: In aspirin sensitive non diabetic patients on chronic aspirin treatment, high glucose added "in vitro" increases platelet responses to agonists, demonstrating that it partially overcomes the inhibitory effect of aspirin on platelet responses with direct effects on platelets, adding another piece of information on the role of hyperglycaemia in the reduction of aspirin sensitivity in diabetes mellitus. The lack of this glucose effect in aspirin resistant patients indicates that when platelets are already aspirin resistant the modulating effect of glucose on platelet sensitivity to aspirin disappears.

Fibrin clot structure characteristics in type 2 diabetes: relationship with cardiometabolic risk factors
S.H. Alzahrani[1], K. Hess[1,2], M. Strachan[2], J. Price[2], R. Cubbon[1], P.J. Grant[1], R.A. Ajjan[1];
[1]University of Leeds, [2]University of Edinburgh, United Kingdom.

Background and aims: Atherothrombotic complications are the main cause of mortality and morbidity in individuals with diabetes. A compact fibrin network structure with increased resistance to fibrinolysis has been documented in individuals at high risk of cardiovascular disease. The aim of the present work was to study the relationship between fibrin clot structure and fibrinolysis and cardiometabolic risk factors and a history of ischemic heart disease (IHD) in a large cohort of type 2 diabetes (T2DM) subjects.
Materials and methods: Using a previously validated turbidimetric assay, clot structure and fibrinolysis were assessed in 875 individuals with T2DM (mean age 68 (CI 67.7-68.3) 450 males) enrolled on the Edinburgh T2DM study. The following parameters were analysed: maximum absorbance (MA), a measure of clot density, time from start to full clot formation (CT), an indicator of clotting potential and lysis time (LT) from full clot formation to 50% lysis, assessing the efficacy of the fibrinolytic pathway. We also measured cardiac inflammatory markers including C-reactive protein (CRP) and complement C3 levels using ELISA techniques.
Results: Female patients had denser clots than males (MA=0.37±0.005 and 0.34±0.004 au respectively, p<0.01) and CT was longer (567.1±6.6 and 522±5.6 sec respectively, p<0.01). LT was prolonged in female subjects at 803.1±19.8 sec compared with males (664.7±12.1 sec; p<0.01). Males with a previous history of IHD had a weak increase in MA (0.35±0.008 and 0.33±0.006 au IHD and non-IHD, respectively, p<0.05), a relationship not seen in female subjects. We analysed the effects of aspirin therapy which was associated with an increase in LT (755±16.1 sec) compared to those not on aspirin (662±12.7 sec, p<0.05). The longer lysis time in aspirin-treated subjects was still evident after excluding individuals with a history of IHD.C-reactive protein (CRP) correlated with MA in both females and males (r=0.24 and 0.27, respectively; p<0.01), whereas C3, which is incorporated into the fibrin network, correlated with LT in both females and males (r=0.25 and r=0.27, respectively; p<0.01). HbA1c showed a weak correlation with MA and LT in male subjects only (r=0.10 and 0.10, respectively, p<0.05), whereas estimated glomerular filtration rate negatively correlated with MA in both males and females (r=0.18 and 0.29 respectively; p<0.01).
Conclusion: i) female patients with diabetes have a more thrombotic clot structure which may contribute to loss of cardiovascular protection in this group. ii) aspirin treatment in diabetes is associated with a paradoxical increase in clot lysis time, suggesting one mechanism for the reduced clinical efficacy of this agent in diabetes. iii) clot structure in T2DM subjects is related to inflammatory and metabolic parameters.

Abnormal glucose tolerance in atrial fibrillation and impact on inflammation, endothelial/platelet function, fibrinolysis, extracellular matrix metabolism and NT-pro-BNP
O. Johansen[1], I. Seljeflot[2], S.F. Ulimoen[1], S. Enger[1], H. Arnesen[2], A. Tveit[1];
[1]Medical department, Vestre Viken, Asker and Baerum Hospital, RUD,
[2]Department of Cardiology, Oslo University Hospital, Ullevål, Norway.

Background and aims: Although an abnormal glucose tolerance (AGT), i.e. diabetes mellitus (DM) or pre-DM, increases the risk for atrial fibrillation (AF) few studies have assessed the extent to which AGT modulates CV risk factors/parameters in patients with AF.
Materials and methods: In a case control study amongst 75-year old subjects with AF or in sinus rhythm (all previously undiagnosed with DM or pre-DM), we examined the prevalence of undiagnosed AGT (by a 75-g oral glucose tolerance test [OGTT] classified according to World Health Organisation criteria) and explored its association to AF duration as well as to circulating CV risk biomarkers of inflammation (C-reactive protein [CRP], Interleukin [IL]-6), endothelial/platelet function (Monocyte chemotactic protein [MCP]-1, P-selectin, CD-40 ligand), fibrinolysis (tissue plasminogen activator antigen [tPAag], plasminogen activator inhibitor-1 [PAI-1] activity), extracellular matrix metabolism (matrix metalloproteinase [MMP]-9, tissue inhibitor metalloproteinase [TIMP]-1) and ventricular function (N-terminal fragment pro-brain natriuretic peptide [NT-pro-BNP]). Between group comparison was conducted non-parametric (Kruskal-Wallis).
Results: Prevalence of undiagnosed DM among the 108 subjects (male/female 73/35, BMI 25.4±3.2) in sinus rhythm and the 46 (male/female 34/12, BMI 25.3±3.7) with AF (median AF duration 5 years) where 3.7% and 13.0%, respectively (p=0.031). Patients with AF duration ≥ 5 years had a higher prevalence of DM and pre-DM (61.1%) as compared to AF duration < 5 years (25%, p=0.0014) or no AF (39.0%, p=0.17). Patients with AF duration ≥ 5 years also had elevated levels of IL-6 (4.27±3.10, p=0.017), MCP-1 (329±82, p= 0.004), CD40 ligand (135±196, p=0.026), PAI-1 activity (16.0±9.5, p=0.004), TIMP-1 (165.6±26.3, p=0.008) and NT-ProBNP (1023±1212, p< 0.001) as compared to those with AF < 5 years (IL-6: 2.89±1.42, MCP-1: 295±85, CD40 ligand: 77±73, PAI-1 activity: 13.7±8.3 TIMP-1: 142.9±20.7, NT-Pro-BNP 741±630) or no AF (IL-6: 2.80±1.85, MCP-1: 290±202, CD40 ligand: 91±95, PAI-1 activity: 10.1±6.7, TIMP-1: 156.1±27.4, NT-Pro-BNP: 186±353). A dosage related, and in part synergistic, impact on the CV risk biomarker levels of AF in the presence of AGT was seen for most parameters assessed; with statistical significance reached for MCP-1, PAI-1 activity and NT-ProBNP (table 1).
Conclusion: Undiagnosed dysglycaemia is prevalent in long standing AF and CV risk biomarkers were adversely modulated by the presence of both AF and AGT. The aggravated CV biomarker profile seen in patients with both AF (especially if long standing) and AGT may play a causal role for the increased CV morbidity and premature mortality observed in this patient group and calls for further attention and research.

Table 1. Levels of circulating CV risk biomarkers according to AF and OGTT status.

Plasminogen activator inhibitor-1 and thrombin activable fibrinolysis inhibitor in patients with type 2 diabetes

A. Blaszkowski, M. Galar, J. Sokolowski, J. Kloczko;
Hematology, Medical University, Bialystok, Poland.

Background and aims: Hypofibrinolysis is a common finding in patients with diabetes mellitus and risk factor for developement of cardiovascular disease. The present study was undertaken to assess the plasma levels of two main inhibitors of fibrinolysis - plasminogen activator inhibitor (PAI-1) and thrombin activable fibrinolysis inhibitor (TAFI) and their relation with clinical and metabolic parameters in diabetic patients with and without vascular complications.
Materials and methods: The study was carried out on 53 patients with type 2 diabetes mellitus (25 women, 28 men). In the examined group 21 patients had coronary heart disease (CHD), 22 hypertension and 17 diabetic rethinopathy. The control group comprised 24 healthy subjects matched for sex and age. The PAI-1 level was measured using Asserachrom PAI-1 set and TAFI by means of Imuclone TAFI ELISA.
Results: In comparison to the healthy controls diabetics revealed significantly higher PAI-1 (27,7±16,4 vs 55,3±29,9 ng/ml, p<0,0001) but lower TAFI levels (115,2±24,0 vs 87,3±20,3%, p<0,0001). The diabetics with CHD and hypertension but not with rethinopathy had significantly increased level of PAI-1 in comparison to the patients without these complications (67,8±33,7 vs 47,1±24,3 ng/ml, p=0,02; 67,0±30,8 vs 47,0±26,7 ng/ml, p=0,01; 57,3±27,5 vs 54,4±31,3 ng/ml, p>0,05, respectively). We found significant positive correlations between the levels of PAI-1 and BMI as well as the levels of triglicerides and negative correlations between PAI-1 and plasmin-antiplasmin complexes (PAP). There were no significant correlations between PAI-1 levels and the levels of HbA1c and GFR. There were no significant differences in the mean levels of TAFI in diabetics with CHD, hypertension and rethinopathy and those without these complications. No significant correlations between TAFI levels and BMI, lipids, HbA1c, PAP and GFR were found.
Conclusion: The data prove the important role of PAI-1 - but not TAFI - in the impairment of fibrinolysis and the developement of cardiovascular complications in patients with type 2 diabetes mellitus.

PAI-1 is an independent maker of metabolic disorders in young adults born small for gestational age

T. Meas[1], S. Deghmoun1, D. Chevenne[2], B. Gaborit[3], M.-C. Alessi[3], C. Lévy-Marchal[1];
[1]Internal medicin, Université Paris 7, [2]Sevice de biochimie hormonale, APHP, Paris, [3]Faculté de médecine Timone, Marseille, France.

Background and aims: Insulin resistance, metabolic syndrome (MS) and cardiovascular diseases have been associated with being born small for gestational age (SGA). However, the mechanisms underlying these associations are still unknown. Fibrinolysis is regulated by plaminogen activator inhibitor type-1 (PAI-1), secreted by the adipose tissue. Increased PAI-1 levels predispose to the development of atherosclerotic plaques prone to rupture. In epidemiological studies PAI-1 levels have been associated with MS and identified as a predictive factor for myocardial infarction. Few studies have examined these associations in subjects born SGA.
Materials and methods: The study population is made of a community-based cohort of young adults, mean age 29.4 years, selected on their birth characteristics. 557 adults born SGA (birth weight under the 10th percentile) were compared to 671 subjects born appropriate for gestational age (AGA) (birth weight between 25th and 75th percentiles). MS was defined using the WHO definition. PAI-1 activity was measured in citrated plasma with a bio immunoassay.
Results: BMI (24.1 ± 4.4 vs 24.2 ± 5.3 kg/m^2) was similar between in AGA and SGA whereas body fat (22.0 ± 8.2 vs 23.2 ± 9.0 %) was significantly increased in the SGA group, p=0.01. MS was more prevalent in the SGA group (8.7%) versus AGA group(5.5%), p=0.03. PAI-1 concentration was correlated with waist circumference, plasma triglycerides, HOMA-IR and associated with male gender and MS in both groups. After adjustment on these variables, PAI-1 concentrations remained significantly increased in the SGA group (12.2 ± 21.2 UI/ml vs 10.0 ± 13.5 UI/ml, p=0.01). PAI-1 concentration above 4.9 UI/ml (median of PAI-1 concentration in the AGA group) was present in 94% of the subjects with MS. Moreover, OR for having elevated PAI-1 was 1.48 [1.08; 1.95] in the SGA group (p=0.005).
Conclusion: PAI-1 plasma concentrations were significantly increased in SGA subjects independently of MS. These data suggest that elevation of PAI-1 concentrations could be taken as an indication of an abnormal secretion at the level of the adipose tissue and could consequently be implicated in the development of the metabolic disorders reported in SGA subjects.

Soluble receptor for advanced glycation endproducts and its inflammatory ligands EN-RAGE and HMGB1 in type 1 and type 2 diabetes mellitus

J. Škrha Jr.[1,2], A. Germanova[2], J. Svarcova[2], M. Kalousova[2], T. Zima[1], J. Škrha[1];
[1]Third Department of Medicine, [2]Institute of Clinical Chemistry and Laboratory Diagnostics, First Faculty of Medicine and General University Hospital, Charles University, Prague, Czech Republic.

Background and aims: The aim of the study was to compare concentration of soluble receptor for advanced glycation endproducts (sRAGE) and its natural pro-inflammatory ligands, EN-RAGE (extracellular newly identified RAGE-binding protein, S100A12) and HMGB1 (high mobility group box-1) with diabetes control, albuminuria, cell adhesion molecules and von Willebrand factor (vWF) in Type 1 (T1DM) and Type 2 (T2DM) diabetes mellitus.
Materials and methods: Total number of 45 T1DM (age 47±13 yrs, diabetes duration 21±12 yrs) and 68 T2DM (age 64±10 yrs, diabetes duration 12±9 yrs) were examined. Control group consisted of 41 healthy persons of comparable age. Serum concentrations of sRAGE, EN-RAGE, HMGB1, ICAM-1, VCAM-1, P-selectin, E-selectin and vWF have been determined by ELISA kits. HbA1c was estimated by HPLC and albuminuria by radioimmunoassay. Both groups of T1DM and T2DM were divided according to microalbuminuria (MA) to MA+ subgroup with MA > 3 g/mol creatinine and MA- subgroup with MA < 3 g/mol creatinine.
Results: Serum sRAGE concentration was significantly higher in both T1DM (1137±78 μg/l, p<0,001) and T2DM (995±63 μg/l, p<0,001) compared to healthy persons and it was higher in MA+ than in MA- subgroups. In T1DM the RAGE ligand (HMGB1 and EN-RAGE) concentrations were more elevated in MA- than in MA+ subgroup in which levels were similar to controls. Significant positive relationship was found between sRAGE and HbA1c (r=0.36, p<0.01), diabetes duration (r=0.58, p<0.01), von Willebrand factor (r=0.36, p<0.005) and albuminuria (r=0.43, p<0.001) in T2DM. sRAGE levels were not related to the above parameters in T1DM, but they significantly correlated with ICAM (r=0.39, p<0.01) and VCAM (r=0.63, p<0.0001). Positive relationship was found between HMGB1 and MA (r=0.79, p<0.05), ICAM (r=0.84, p<0.05) and E-selectin (r=0.79, p<0.05) in MA+ T1DM. No relationship was observed between sRAGE and its ligands.
Conclusion: Serum sRAGE concentration reflects protective ability against AGEs created more significantly in diabetes with increased albuminuria. It corresponds to higher sRAGE levels in these patients. Our results demonstrate differences in RAGE ligands between T1DM and T2DM. Their higher levels found in younger T1 and T2 diabetic patients with other risk factors compared to older patients with already established micro- and macrovascular disease are suspicious from the higher activity promoting RAGE ligand creation in former patients. Their role as markers in development of chronic vascular complications will be evaluated in the follow-up study.

Results:

	T1DM		T2DM		Controls
	MA- (n = 38)	MA+ (n = 7)	MA- (n = 50)	MA+ (n = 18)	(n = 41)
HbA1c (%, IFCC)	7.40^{a}±0.22	8.33^{a}±0.25	6.43^{a}±0.24	8.10^{a}±0.69	3.60±0.20
MA (g/mol creat.)	1.15±0.14	12.04^{a}±5.35	1.27±0.15	47.94^{a}±11.51	0.80±0.10
HMGB1 (μg/l)	2.45^{by}±0.27	1.02±0.27	2.58^{a}±0.29	2.65^{a}±0.42	0.95±0.14
sRAGE (μg/l)	1078±89	1461^{a}±117	877±55	1322^{ay}±162	824±48
EN-RAGE (μg/l)	277^{ax}±33	125±33	266^{a}±28	365^{a}±53	110±10
vWF (μg/l)	110±7	135^{a}±25	109±5	177^{ay}±17	88±32
ICAM (μg/l)	249^{b}±12	320^{b}±42	285^{b}±26	325^{b}±35	206±10
VCAM (μg/l)	863^{a}±72	1194^{a}±147	796^{a}±39	991^{a}±107	365±11

Results are mean±SEM, significant difference to controls: $^{a}p<0.001$, $^{b}p<0.01$, and between MA+ and MA-: $^{x}p<0.05$, $^{y}p<0.01$.

Intermittent high glucose promotes expression of proinflammatory cytokines in monocytes

L. Yang, W. Qi;
Endocrinology and metabolism, Taian City Central Hospital, China.

Background and aims: Diabetes confers an increased propensity to atherosclerosis. Postprandial hyperglycemia seems to impose more deleterious effects on vessels. The aim of this study was to examine expression of proinflammatory cytokines from monocytes under fluctuating glucose condition.
Materials and methods: Monocytic cells (THP-1) were divided into four groups and cultured in the presence of 5mmol/l or 15 mmol/l glucose and in a fluctuating condition(12h exposure to 15mmol/l glucose or mannitol medium followed by 12h exposure to 5 mM glucose or mannitol medium) respectively.Concentrations of IL-6 and TNF-α in the supernatants and CD11b MFI(mean fluorescence intensity) in monocytes surfaces were measured after 72h' culture.
Results: Monocytes exposed to fluctuating glucose condition expressed highest levels of IL-6,TNF-α and CD11b, and in the second place were monocytes exposed to fluctuating mannitol condition. Monocytes cultured in 15mmol/l glucose medium expressed a lower level of cytokines than those cultured in such fluctuating conditions, but a higher level compared with those in 5mmol/l glucose medium (for IL-6: 204.99±25.08 pg/ml, 179.97±37.14 pg/ml,151.61±21.82 pg/ml and 122.41±18.19 pg/ml respectively; for TNF-α:148.73±15.71 pg/ml, 131.46±16.67 pg/ml, 96.91±15.14 pg/ml and 74.08±7.46 pg/ml respectively; for CD11b MFI: 77.73±7.51,68.75±4.01, 61.58±3.05 and 53.82±6.68 respectively). Differences of these cytokines among the four groups were statistically significant.
Conclusion: The results indicate that exposure to fluctuating glucose concentrations enhances activation of monocytes compared with stable elevations in glucose concentration. The effects are partly attributable to the inherent osmotic changes.These findings indicated that reducing fluctuations in circadian glucose concentrations has important implications for the treatment strategies in diabetic patients with macrovascular complications.

1333

Association of urine adiponectin levels and marker of endothelial damage in type 2 diabetes without microalbuminuria

Y.J. Lee[1], K.S. Suh[2], M.C. Choi[1], Y.C. Hwang[1], S. Chon[3], I.-K. Jeong[3], S. Oh[3], K.J. Ahn[3], H.Y. Chung[3], J.-T. Woo[3], S.-W. Kim[3], J.-W. Kim[3], Y.K. Choi[4], Y.S. Kim[3];
[1]Department of Endocrinology and Metabolism, Kyung Hee University School of Medicine, [2]Endocrine Research Institute, Kyung Hee University School of Medicine, [3]Department of Endocrinology and Metabolism,Endocrine Research Institute, Kyung Hee University School of Medicine, [4]Department of Endocrinology and Metabolism, Pochon CHA University, Seoul, Republic of Korea.

Background and aims: Urinary albumin excretion (UAE) and intima media thickness (IMT) of the carotid artery are considered subclinical markers of endothelial cell damage preceding atherosclerosis in type 2 diabetes. Recent studies reported that Urine (U-) adiponectin was significantly increased in type 2 diabetes. U-adiponectin reflects early vascular damage in a more efficient way compared to serum adiponectin, which is easily influenced by metabolic changes. Our observational study assessed whether there is an association between U-adiponectin and UAE, change of IMT at baseline and after 1 year in type 2 diabetes without microalbuminuria.
Materials and methods: We enrolled 90 (37 men, 53 women) type 2 diabetic patients without microalbuminuria who presented with good glycemic control for 1 year. Total plasma (P-) and U-adiponectin were determined by enzyme-linked immunosorbent assay kit. U-adiponectin levels were adjusted for urinary creatinine excretion. The measurements were performed on both common carotid arteries avoiding areas of atherosclerotic plaque formation, and the mean IMT was used in this study.
Results: Baseline characteristics of the patients were: age 58.7 ± 8 years, mean body mass index (BMI) 25.1 ± 3.1 kg/m^2, HbA1c value 6.9 ± 1.2 %, and UAE 8.2 ± 6.8 ug/mg creatinine. The mean duration of diabetes was 9.5 years. BMI, HbA1c and triglyceride levels were not significantly different between baseline and at 1 year (p=.160, p=590, p=.418, respectively). Mean IMT was 0.70 ± 0.1 mm at baseline, and slightly increased to 0.75 ± 0.1 mm after 1 year, with a statistically significant difference (p<0.001). Baseline P-adiponectin and U-adiponectin were 13.0 ± 15.7 ug/mL, 4.7 ± 6.8 ug/mg creatinine,

respectively, and at 1 year, 11.0 ± 11.4 ug/mL, 4.8 ± 6.5 ug/mg creatinine, not demonstrating a significant difference (p=.226, p=.913, respectively). We analyzed the two groups, one with the increased IMT at 1 year (n=53) compared to the baseline IMT and the other with the decreased IMT at 1 year (n=31). HbA1c was significantly higher in the increased IMT group compared to the decreased IMT group (7.1 ± 0.1 % vs 6.6 ± 0.2 %, p=.039), while BMI, blood pressure and lipid levels were not significantly different between the two groups. U-adiponectin was higher in the increased IMT group than in the decreased IMT group, although there was no significant difference (5.1 ± 6.9 ug/mg creatinine vs 3.2 ± 4.6 ug/mg creatinine, p=.133). U-adiponectin revealed a significant positive correlation with UAE (r=.259, p=.014), while it was not significantly correlated with IMT (r=-.100, p=.350) in our study subjects.
Conclusion: Our study implies that U-adiponectin levels may reflect early glomerula vascular damage in the pre-albuminuric level in type 2 diabetic patients. On the other hand, U-adiponectin may not be associated with macrovascular damage. The exact mechanism and association between U-adiponectin and vascular damage need further investigating.

Formation of methionine-sulfoxide at position 1606 of Von Willebrand Factor inhibits cleavage by ADAMTS-13: a new prothrombotic mechanism promoted by oxidative stress in diabetes

F. Zaccardi[1], D. Pitocco[1], S. Lancellotti[2], V. De Filippis[3], B. Rocca[4], R. De Cristofaro[2], G. Ghirlanda[1];
[1]Internal Medicine, Catholic University, Rome, [2]Hemostasis Research Center, Catholic University, Rome, [3]University of Padua, [4]Pharmacology, Catholic University, Rome, Italy.

Background and aims: An enhanced formation of reactive oxygen species and peroxynitrite occurs in diabetes. Peroxynitrite oxidizes methionine and tyrosine residues to methionine sulfoxide (MetSO) and 3-nitrotyrosine (NT), respectively. Notably, ADAMTS-13 cleaves von Willebrand factor (VWF), which bind and activate platelets in the microcirculation, exclusively at the Tyr1605-Met1606 peptide bond. We hypothesized that peroxynitrite could oxidize either or both of these amino acid residues, thus potentially affecting ADAMTS-13-mediated cleavage.
Materials and methods: Nonsmokers-healthy subjects (n=13, age 38-55), without risk factors for cardiovascular disease and 16 age- and sex-matched subjects with type 2 DM (T2DM) not on chronic medications including NSAIDs, vitamin E, or statins, were consecutively enrolled. The plasma level of VWF was measured as antigen and ristocetin cofactor. Moreover, we tested our hypothesis using synthetic peptide substrates based on: (1) VWF Asp1596-Ala1669 sequence (VWF74) and (2) VWF Asp1596-Ala1669 sequence containing nitrotyrosine (VWF74-NT) or methionine sulfoxide (VWF74-MetSO). The peptides were treated with recombinant ADAMTS-13 and the cleavage products analyzed by RP-HPLC. As adjunctive analysis, in 15 type 1 diabetic subjects we explored the relationship between the 24hrs-glycemic variability (obtained from Continuous Glucose Monitoring System and measured with CONGA index) and total carbonyls (a surrogate marker of oxidative stress) and ADAMTS-13 activity.
Results: T2DM subjects showed a significantly increased plasma level of VWF (p<0.001). The carbonyl content of VWF (a marker of oxidative modification of the protein) was significantly higher in T2DM than in controls (p<0.01). Moreover, compared to VWF purified from control subjects, VWF preparations from T2DM patients showed a relative resistance to ADAMTS-13 hydrolysis. In particular, VWF74 oxidized by peroxynitrite underwent a severe impairment of its hydrolysis. Likewise, VWF74-MetSO was minimally hydrolyzed, whereas VWF74-NT was hydrolyzed slightly more efficiently than VWF74. Oxidation of purified VWF multimers did not alter their electrophoretic pattern nor their ability to induce platelet aggregation by ristocetin. Furthermore, we found a strong and positive linear correlation between CONGA1 and total carbonyls and ADAMTS-13 activity (P=0.013, R=0.904; P=0.003, R=0.952, respectively).
Conclusion: Overall, these findings indicate that oxidative stress and glycemic variability may contribute to prothrombotic effects, hindering the proteolytic processing by ADAMTS-13 of high-molecular-weight VWF multimers.

1335

Association of serum endothelin-1 with insulinaemic status in prediabetic and newly diagnosed type 2 diabetic subjects

I. Khan[1], S. Mohajan[2,3], R.M. Mazumder[2,3], D. Sikdar[3], M.O. Faruque[2], Z. Hassan[1], L. Ali[2,4];
[1]Dept of Physiology and Molecular Biology, BIRDEM, Dhaka, [2]Dept of Biochemistry and Cell Biology, BIRDEM, Dhaka, [3]Dept of Biochemistry and Molecular Biology, Chittagong University, Chittagong, [4]Dept of Biochemistry, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh.

Background and aims: Endothelin-1 (ET-1), an atherogenic marker, has been shown to be raised in T2DM subjects. However, the factors contributing to the elevation of ET-1 in T2DM is still unclear. Since IFG and IGT are intermediate stages in the development of diabetes, we have studied ET-1 in relation to glycaemic and insulinemic status in these prediabetic groups to get better insight on this issue.
Materials and methods: A total number of 160 subjects of Bangladeshi origin, consisting of 18 IFG, 47 IGT, 46 newly diagnosed T2DM patients and 49 healthy subjects were included in the study. Glucose was estimated by glucose-oxidase, lipids by enzymatic- colorimetric, and insulin and endothelin-1 were estimated by enzyme linked immunosorbent assay (ELISA). Results were expressed as mean±SD and appropriate tools were used in statistical comparison.
Results: Age and BMI were matched among all the groups. Absolute insulin (μIU) level in IGT and T2DM were significantly higher compared to the controls (p<0.001 for both). HOMA%B (mean±SD) was significantly lower in IFG and T2DM groups (p=0.004 and <0.001) and higher in IGT (p=0.006) group compared to controls. HOMA%S was significantly lower in IGT and T2DM groups (p=0.002 and 0.003 respectively) compared to the Control, but it did not show any significant difference between IFG and Control groups. Lipid levels were almost similar in all three groups compared to the Control except significantly higher triglyceride and total cholesterol level in T2DM groups (p=0.001 and p=0.024 respectively). Mean value of serum endothelin-1 was 6.85±4.4, 10.34±4.7, 10.14±6.8 and 10.48±5.7 in the Control, IFG, IGT and T2DM subjects respectively. This atherogenic marker was found to be significantly higher in prediabetic (IFG: p=0.009 and IGT: p=0.006) and T2DM (p=0.001) groups. On Spearman's correlation analyses ET-1 showed association with fasting glucose in T2DM subjects, although it did not show any significant correlation with HOMA%S or HOMA%B in the prediabetic and T2DM groups. Multinomial logistic regression analyses showed that ET-1 was associated with all the three hyperglycemic groups (IFG: p=0.005; IGT: p=0.007 and T2DM: p=0.003) when adjusted for age, WHR and gender.
Conclusions: Endothelin-1 is raised in hyperglycemic conditions regardless the stages of its natural history and this elevation is directly associated with hyperglycemia rather than insulin deficiency or insulin resistance.

Inducible Nitric Oxide Synthase (iNOS)regulation by Ca^{2+}/Calmodulin-dependent protein kinase II in vascular Smooth Muscle Cells (vSMCs) from diabetic rats

N. Di Pietro[1,2], P. Di Tomo[1,2], A. Giardinelli[1,2], S. Di Silvestre[1,2], C. Pipino[1,2], C. Morabito[3,2], G. Formoso[4,2], M.A. Mariggiò[3,2], A. Consoli[4,2], A. Pandolfi[1,2];
[1]Department of Biomedical Sciences, University "G. d'Annunzio", [2]Aging Research Center , Ce.S.I., "Gabriele d'Annunzio" University Foundation, [3]Department of Basic and Applied Sciences, University "G. d'Annunzio", [4]Department of Medicine and Aging Science, University "G. d'Annunzio", Chieti, Italy.

Background and aims: In diabetes, increased cytokine plasma levels could induce iNOS expression contributing to vascular damage. In addition to transcriptional regulation, iNOS activity may be posttranslationally regulated by palmitoylation and intracellular trafficking. It has been recently demonstrated that the multifunctional protein kinase CaMKII, a known contributor to vascular dysfunction in diabetes, may also play a significant role in iNOS-specific trafficking and activity following cytokine induction. Thus, the aim of the present study was to investigate the relationships between cytokine increased iNOS activity and Ca^{2+}/CaMKII/CaMKIIdelta2 pathway involvement in vSMCs from diabetic rats (DR).
Materials and methods: We measured iNOS expression (RT-PCR, Western Blot) and activity (conversion L-(3H)-arginine into L-(3H)-citrulline), intracellular Ca^{2+} levels (fluorescence video imaging), CaMKII phosphorylation

(Western Blot), iNOS/CaMKIIdelta2 co-immunoprecipitation (Western Blot) and nitrotyrosine levels (immunofluorescence) in cultures of aortic vSMCs from 10 diabetic (90% pancreatectomy, DR) and 10 control (sham surgery, CR) rats, after 24 hrs incubation with 20 μg/ml Lipopolysaccharide (LPS).
Results: LPS increased iNOS expression to the same extent in CR and DR, while iNOS activity was about 7 folds greater in DR. As to the effect of LPS on increased Nitric Oxide (NO) production in DR, exposure to LPS led to an increase of intracellular calcium levels (1.9 folds increase) and Ca^{2+}-dependent CaMKII phosphorylation (3 folds increase) followed, as expected, by the absence of iNOS/CaMKIIdelta2 co-immunoprecipitation. These LPS effects were associated to the greater induced iNOS-specific activity in DR. In CR, instead, LPS failed to affect these parameters, which were not different from basal levels after LPS stimulation. In addition, the increased iNOS activity in DR was accompanied by a significant increase in intracellular nitrotyrosine levels (1.5 folds increase).
Conclusion: In conclusion, as compared to CR vSMCs, DR cells showed a greater LPS induced iNOS activity associated to an activation of Ca^{2+}/CaMKII/CaMKIIdelta2 pathway. In addition, as we have previously shown, DR cells exhibit in this culture conditions a marked increase in O^{2-} levels. Thus, the LPS increased NO release in diabetic pro-oxidant milieu gets converted into peroxinytrite and then enhanced nitrotyrosine generation. Together these results indicate for the first time that signal pathway involving CaMKII contributes to increase iNOS activity and nitrotyrosine generation in diabetes and might provide new insight in the mechanisms linking diabetes and atherosclerosis.

1337

Multifactorial risk factor intervention in type 2 diabetic patients significantly improves global arginine bioavailability ratio
N.J. Tripolt[1], A. Meinitzer[2], M. Eder[1], W.B. Graninger[3], T.R. Pieber[1], T.C. Wascher[4], H. Sourij[1];
[1]Internal Medicine, Div. of Endocrinology and Nuclear Medicine, Vascular Biology Research Group, Medical University of Graz, [2]Clinical Institute of medical and chemical laboratory diagnostics, Medical University of Graz, [3]Internal Medicine, Div. of Rheumatology, Medical University of Graz, [4]Department of Internal Medicine, Hanuschkrankenhaus, Vienna, Austria.

Background and aims: Endothelial dysfunction is defined by reduced bioavailability of nitric oxide (NO) and has been shown to be associated with increased cardiovascular risk. The unique source for NO-synthesis is arginine and ornithine and citrulline are the products of arginine metabolism. Global arginine bioavailability ratio (GABR) is defined as arginine/(ornithine + citrulline). Recently published data showed an inverse association between GABR and cardiovascular events. The aim of our study was to investigate the impact of a multifactorial risk factor intervention on GABR as a cardiovascular surrogate parameter in type 2 diabetic patients.
Materials and methods: We investigated type 2 diabetic patients, that did not reach treatment targets according to current local guidelines in two out of three oft the following parameters: HbA1c <6,5%, LDL-cholesterol <100 mg/dl or blood pressure <130/80 mmHg. GABR was measured at baseline and after 3 months. During this time therapy was intensified according to current guidelines aiming to reach the treatment targets. Arginine, ornithine and citrulline were chromatographically determined after precolumn-derivatisation followed by fluorescent detection. Intima media thickness was measured by B-mode ultrasound.
Results: We investigated 41 patients (25 males/16 females) with a mean age of 60±10 years. Baseline characteristics and treatment outcomes are shown in table 1. Intensified risk factor management significantly improved GABR (0,33±0,12 at baseline vs. 0,38±0,14 after 3 months; p=0,018). A significant improvement was only seen in patients with short diabetes duration (<5 years) whereas in patients with longer diabetes duration improvement did not reach statistical significance. A linear model including the duration of diabetes, the change of LDL-cholesterol, change of HbA1c, change in blood pressure turned out diabetes duration as the only significant predictor (p=0.049) of GABR improvement. Furthermore the change of GABR was inversely correlated with mean intima media thickness (r=-0,381, p=0.014).
Conclusion: In type 2 diabetic patients intensified risk factor intervention improves global arginine bioavailability ratio as a parameter of endothelial function. Duration of diabetes seems to be an important factor influencing the capacity of GABR improvement.

Treatment outcomes

	Baseline	3 months	p-value
sex (m/f)	25/16		
age (years)	60±10		
Duration of diabetes (years)	8±7		
LDL cholesterol (mg/dl)	108±52	79±48	<0,001
HDL cholesterol (mg/dl)	46±13	50±16	<0,001
HbA1c (%)	8,5±1,2	7,9±1,4	<0,001
RR systolic (mmHg)	151±17	131± 23	<0,001
RR diastolic (mmHg)	89±9	77± 14	<0,001

Formation of methylglyoxal-adducts in plasma is associated with LDL and triglyceride level: implications for diabetic atherosclerosis
Z. Turk[1], J. Boras[2];
[1]Department for Laboratory Medicine, [2]Department for Diabetic Complications, Vuk Vrhovac University Clinic for Diabetes, Zagreb, Croatia.

Background and aims: Protein glycation leading to AGE is enhanced in diabetes by increases in blood glucose *per se,* and collaterally, by endogenous production of reactive carbonyls. Low weight α-dicarbonyls are formed as glycolytic intermediates during metabolic conversion of glucose and/or during lipid peroxidation. Among AGE precursors, methylglyoxal (MG) is considered as one of the key intermediates. We hypothesized it to be a common product of both carbonyl and oxidative stress, and investigated the MG biogenesis in relation to glycemic and lipid status in diabetic patients.
Material and methods: Serum and urine MG-adduct content was measured by DELFIA method in 83 diabetic patients and 20 controls. Fasting (FG) and postprandial (PPG) glucose level, HbA1c, LDL and HDL cholesterol, plasma triglyceride and homocysteine level were determined along with routine biochemical parameters.
Results: Significant positive relationship was observed between serum level of MG-adducts and LDL (r=0.31 p=0.003) whereas fasting glucose correlated inversely (r= -0.33 p=0.001) as well as PPG (r= -0.23 p=0.041) and HbA1c (r= -0.22 p=0.036). Similarly, significant correlations were also found between urinary levels of MG-adducts and postprandial glucose (r= -0.28 p=0.023), serum triglycerides (r=0.31 p=0.003), homocystein (r=0.57 p=0.0007), HDL (r= -0.28 p=0.007) and urine albumine/creatinine ratio (r=0.53 p=0.002). Stepwise linear regression was performed using serum or urine MG-adducts as dependent variable and HbA1c, fasting and postprandial glucose, LDL, HDL, triglycerides, serum creatinine, homocystein and urine albumine/creatinine ratio as independent variables. Of these, only LDL-cholesterol (regression coefficient=0.29) and FG (regression coefficient=-0.28) were independent predictors of MG-adducts in serum (p<0.00046), whereas urine albumine/creatinine ratio, PPG, and triglycerides were independently associated with their urine content (p<0.0062). LDL-cholesterol >3.0 mmol/L discriminate patients who had a higher serum level of MG-adducts (median (10^{th} and 90^{th} percentile) 465 (251-1254) *vs* 331(169-706) mgEq/L, p=0.0052), although there was no between-subgroup difference in glycemic control. Patients on statin treatment had lower MG-adducts although the difference did not reach statistical significance. The positive relationship between LDL-c and MG-adducts (r=0.38, p=0.042) was noted in the patients (n=54) free of statin treatment, whereas in the statin-treated subgroup, there was an inverse tendency (r=-0.28, p=0.83) but no significant yet. A significant correlation between homocysteine and urinary excretion of MG-adducts (r=0.8; p=0.02) was recorded in patients with a history of macrovascular disease.
Conclusion: A highly significant relationship between LDL and MG-adduct production, as well as tight correlation between triglycerides and urinary MG-adduct excretion suggest that lipoxidation and glyceraldehyde-3-phosphate route, along with the glycolytic pathway, might be an important source of MG generation. The glycotoxin methylglyoxal seems to be a common factor linking the two dominant metabolic changes in diabetes, hyperglycemia and intensive lipolysis, with vascular pathobiochemistry of diabetes.

Vitamin B1 analogue benfotiamine improves survival and proliferation of diabetic or high glucose challenged resident cardiac stem cells

R.G. Katare, A. Oikawa, A. Caporali, C. Emanueli, P. Madeddu;
Bristol Heart Institute, University of Bristol, United Kingdom.

Background and aims: Diabetes mellitus (DM) is a potent and prevalent risk factor for coronary artery disease and heart failure. Furthermore, DM directly impinges on the heart's function by accelerating the aging of cardiomyocytes and resident cardiac progenitor cells (CPCs). Treatments able to prevent CPC senescence and thereby preserve heart reparative capacity are urgently needed. Our earlier studies demonstrated the ability of vitamin B1 analog benfotiamine (BFT) to prevent the development of diabetic cardiomyopathy. Here, we aimed to verify whether BFT may benefit the survival, proliferation and differentiation of resident CPCs.
Methods and results: Sca-1$^+$ CPCs were extracted from left ventricle of STZ induced type-1 DM mice after 20 weeks of DM induction using commercially available kit. Flowcytometric analysis revealed marked reduction in the number (23±4% vs 12±2%, P<0.01) and increased apoptosis (28±3% vs 10±4%, P<0.001) of CPCs from diabetic mice compared to age-matched healthy controls (n=7 mice per group). When cultured under normal glucose (5%) conditions, diabetic CPCs showed increased apoptosis and reduced protein expression of the cell survival Pim-1/Bcl-2 signalling pathway and significantly lost their ability to differentiate into cardiomyocytes when exposed to differentiation medium. However, treating diabetic animals with BFT (70mg/kg/day, for 16 weeks), markedly inhibited the apoptosis of CPCs through activation of Bcl-2 and phosphorylation of Bad. Importantly, BFT treatment induced 2 fold increase in proliferation of CPCs that was markedly attenuated by DM (P<0.01). In addition BFT also increased the differentiating ability of CPCs into cardiomyocytes, as evidenced by measuring the percent of cells positive for α-sarcomeric actin and connexin-43. Finally, CD45$^-$ CD90$^+$CD105$^+$ CPCs isolated from atrial appendages of patients undergoing on-pump by pass cardiac surgery were exposed to high glucose (30μM) with or without BFT (150μM). Importantly, high glucose induced apoptosis (55±5% vs 12±4%, P<0.001) and reduced the proliferation (45±8% vs 80±4%, P<0.001) and differentiation potential of human CPCs, with these effects being prevented by BFT (P<0.01 for all comparisons).
Conclusion: Both DM and high glucose cause quantitative and functional deficits in CPCs. BFT contrasted these detrimental effects in a murine diabetic model as well as in *in vitro* assays using human CPCs exposed to high glucose. These data highlight the direct protective action of BFT on CPCs and potential underpinning mechanisms centred on survival Pim-1/Bcl-2 signalling pathway. Thus, BFT merit attention as a global therapeutic target to combat DM-associated cardiac damage.

Gene silencing of Toll-like receptor attenuates myocardiac apoptosis in diabetic mice

Y. Zhang[1,2], H. Zhu[1], X. Zheng[1], X. Zhang[1], N. Jiang[1], A. Shunnar[1], N. Tong[2], T. Peng[1], W. Min[1];
[1]University of Western Ontario, London, Canada, [2]West China Hospital, Chengdu, China.

Background and aims: Myocardiac apoptosis is an early event involved in the process of cardiomyopathy in diabetes mellitus. Toll-like receptors (TLR) signaling triggers cell apoptosis through multiple mechanisms. Up-regulation of TLR4 expression has been shown in diabetic hearts. This study aims to delineate the role of TLR4 in cardiac apoptosis, and to block this process through gene silencing of TLR4 in diabetic hearts.
Materials and methods: The C57/BL6 mice were made diabetic by ip injection of streptozotocin (STZ, 150mg/kg body weight). Three days after STZ treatment, the diabetes was confirmed by blood glucose level. Diabetic mice were treated with 50 μg of TLR4 shRNA (treatment group) or scrambled shRNA (control group). Other control groups include non-treated diabetic mice (diabetes group) and naïve mice (normal group).
Results: After 7 days of hyperglycemia, the level of TLR4 in the heart tissue was significantly elevated in the diabetic mice, as comparing normal mice. Treatment of TLR4 shRNA knocked down the gene expression as comparing control mice, as well as diminished its elevation in diabetic mice. Pathologically, apoptosis was evident in the cardiac tissues of diabetic mice, as detected by TUNEL assay. In contrast, treatment with TLR4 shRNA minimized apoptosis in heart tissues. Mechanistically, caspase 3 activation was remarkably inhibited in the mice that were treated with TLR4 shRNA, but not in the mice treated with control shRNA or non-treated mice. Furthermore, gene silencing of TLR4 resulted in suppression of apoptosis cascades, such as caspase 3, caspase 8 and Fas gene expression.
Conclusion: In summary, we demonstrated here a piece of novel evidence that TLR4 plays a critical role in cardiac apoptosis. This is the first demonstration of preventing in cardiac apoptosis in diabetic mice through gene silencing of TLR4 gene.

Prevalence of glucose intolerance in patients with chronic hepatitis C

G. Radulian[1], F. Rusu[2], A.D. Dragomir[2], G. Enache[2], M. Jinga[3], V. Stoica[3], D. Cheta[3], E.D. Rusu[1];
[1]National Institute of Diabetes, Nutrition and Metabolic Diseases, [2]Healthy Nutrition Foundation, [3]University of Medicine Carol Davila, Bucharest, Romania.

Background and aims: The association of glucose intolerance with chronic hepatitis C (CHC) virus infection remains controversial. The aim of this study was to evaluate the prevalence of glucose intolerance by oral glucose tolerance test (OGTT) in patients with CHC in comparison with matched controls and to analyze if adipocytokines levels correlate with insulin secretion (IS) and insulin resistance (IR).
Materials and methods: 176 consecutive outpatients with CHC (group A) and 123 subjects individually (group B) matched for age, sex and body mass index (BMI) were included. OGTT was performed in all cases with HbA1c over 5.5%. Glucose intolerance was defined as IFG (impaired fasting glucose), IGT (impaired glucose tolerance) or diabetes. IR was determined using Homeostasis model assessment (HOMA-IR). The liver fibrosis was non-invasively assessed using the Forns index; a value < 4.2 excludes liver fibrosis and a value > 6.9 is a predictor for significant fibrosis.
Results: The average age was 56.21±10.28 in group A and 54.27±10.22 years in group B. After age and BMI adjustment, patients with CHC had significantly higher prevalence of glucose intolerance (23.86% vs 9.75%, P = 0.037). Median HOMA-IR (3.75 versus 1.23), adiponectin (6.72 versus 2.98 μg/ml), TNF alpha (2.79 versus 0.61 pg/ml), IL-6 (4.78 versus 1.81 pg/ml) were significantly higher in CHC patients (all p < 0.05). In patients with CHC, by multiple linear regression, independent predictors of HOMA-IR included the body mass index, apparent liver disease duration, and the serum levels of leptin, TNF alpha, IL-6 (positive correlation) and adiponectin (negative correlation). In patients with HCH infection, plasma insulin and C-peptide levels were lower (al p <0.05).
Conclusion: In hepatitis C patients**,** higher prevalence of glucose intolerance are present. Adipocytokines and inflammatory cytokines play an important part in this relationship. Screening for diabetes (HbA1c or OGTT) is necessary in patients with hepatitis C.

Prevalence and determinants of diabetes mellitus in Dutch patients with liver cirrhosis

N. Wlazlo[1], H.J.B. Beijers[1], E.J. Schoon[2], H.P. Sauerwein[3], C.D.A. Stehouwer[4], B. Bravenboer[1];
[1]Department of Internal Medicine, Catharina Hospital, Eindhoven, [2]Department of Gastroenterology, Catharina Hospital, Eindhoven, [3]Department of Endocrinology and Metabolism, Academic Medical Centre, Amsterdam, [4]Department of Internal Medicine and Cardiovascular Research Institute Maastricht, Maastricht University Medical Centre, Netherlands.

Background and aims: The reported prevalence of type 2 Diabetes mellitus (DM2) in patients with liver cirrhosis is 20-40%, about five times higher than in the general population. However, these data were never adjusted for classical risk factors for DM2, like age, body mass index (BMI) or family history of DM2 (first or second degree relatives). We therefore investigated the association between cirrhosis and DM2 controlling for known risk factors for DM2.
Materials and methods: We reviewed medical files for presence of DM2 and potential confounders in 94 patients with cirrhosis visiting our hospital between 2001 and 2009 (cases) and compared these to a control group of 107 patients with non-ulcer dyspepsia (NUD). Multiple logistic regression analysis was used to adjust for potential confounders.
Results: The etiology of our cirrhosis population was alcohol (59%), viral hepatitis (10%), biliary cirrhosis (3%) or cryptogenic (28%). Prevalence of DM2 was significantly higher in patients with cirrhosis than in controls: 35/94 (37%) vs. 7/107 (7%) (OR 8.5, 95%CI 3.5 - 20.2, p < 0.001). After adjustment for age, sex, family history of DM2, alcohol use and BMI, cirrhosis remained significantly associated with DM2 (OR 13.6, 95% CI 4.3 - 42.9, p < 0.001). Most DM2 was already diagnosed before diagnosis of cirrhosis (21/35, 60%) or was incidentally found together with cirrhosis (5/35, 14%). In multivariate analysis in patients with cirrhosis, male sex (OR 4.6, 95% CI 1.3 - 15.9, p = 0.016), positive family history of DM2 (3.7, 95% CI 1.0 - 12.8, p = 0.042) and BMI (OR 1.2 per kg/m^2, 95% CI 1.0 - 1.3, p = 0.015) were positively associated with DM2, whereas alcohol consumption protected (moderate vs. no alcohol consumption (OR 0.11, 95% CI 0.02 - 0.57, p = 0.009), excessive vs. no alcohol consumption (OR 0.14, 95% CI 0.03 - 0.63, p = 0.010)). Etiology and severity of the cirrhosis, expressed in Child-Pugh score, were not associated. The final model explained about 30% of diabetes prevalence in cirrhosis.
Conclusion: Liver cirrhosis was strongly associated with DM2, even after adjustment for age, BMI and family history of DM2. Although sex, family history, BMI and alcohol consumption were significantly associated with the presence of DM2, this only explained part of the high DM2 prevalence in cirrhosis. Therefore a liver-specific factor, such as low-grade inflammation, might cause DM2 in cirrhosis.

1343

Chromatin structure and Sirt1 and PGC-1alpha expressions in liver cells of NOD mice

F.G. Ghiraldini[1], I.M. Toni[2], M.L.S. Mello[1];
[1]Anatomy, Cell Biology, Physiology and Biophysics, [2]Genetics, Evolution and Bioagents, State University of Campinas, Brazil.

Background and aims: Evidences point out that hyperglycemia caused by diabetes mellitus is the main factor that contributes to early-ageing in diseased patients. This metabolic alteration could lead to changes in chromatin structure and dynamics, as those previously observed in hepatocytes of a group of NOD mice presenting glycemia higher than 600 mg/dl. Alterations in chromatin structure caused by epigenetic factors may change the expression profiles of genes involved in cell ageing. Sirt1 is a NAD^+ dependent deacetylase recently related to cellular metabolic changes and ageing. Together with the transcriptor factor PGC-1α, Sirt1 could act as a nutritional sensor. The aim of this study was to compare chromatin accessibility to micrococcal nuclease (MNase) and expressed Sirt1 and PGC-1α protein in liver cells of moderate and severe diabetic adult and non-diabetic mice.
Materials and methods: Young adults (8 weeks old) with moderate diabetes (glycemia: 200-400 mg/dl), severe (glycemia > 500 mg/dl) diabetic adults and old non-diabetic (56 weeks old) mouse groups were used (n = 5). Normoglycemic Balb/c and NOD mice with the same ages as the diabetic animals were used as controls. Chromatin accessibility was evaluated by Mnase assay, followed by DNA extraction and agarose gel electrophoresis. PGC-1α and Sirt1 were determined by Western Blot for the same groups.
Results: The chromatin in mice with severe diabetes presented the highest unraveling degree (2.62 ± 0.44, $P_{<0.05}$) in comparison with that of the control with the same age (Balb 0.66 ± 0.22; NOD 0.46 ± 0.11). Although chromatin accessibility index of the older mice was higher in comparison with that of young mice (1.41 ± 0.2 vs 0.67 ± 0.18, $P_{<0.05}$), it was still lower than that in mice with severe diabetes (2.62 ± 0.44, $P_{<0.05}$). The Sirt1 protein was abundant in mice with severe diabetes compared to their respective controls (moderate diabetic mice 1.62 ± 0.17 vs control Balb/c 0.92 ± 0.07, $P_{<0.05}$; severe diabetic mice 1.60 ± 0.18 vs control Balb/c 0.94 ± 0.09 and normoglycemic NOD 0.75 ± 0,09 $P_{<0.05}$) while old mice presented the lowest values (0.30 ± 0.03) in comparison to young mice (1.00) ($P_{<0.05}$). The PGC-1α abundance was higher than that of controls only when considering mice with severe diabetes (2.15 ± 0.4) vs Balb/c mice (0.66 ± 0.06) and normoglycemic NOD (0.88 ± 0.42). Similar to the Sirt1 expression, PGC-1α abundance was lower (0.51 ± 0.15 fold) in older mice in comparison with young ones.
Conclusion: Severe hyperglycemia induces enhancement of an open form of chromatin in hepatocytes, surpassing the phenotype exhibited in old specimens. Sirt1, together with PGC-1α, could act as nutritional sensor, because it is highly expressed in severe diabetic mice but attains normal levels in normoglycemic mice of same age. Therefore, the decondensed chromatin phenotype observed in hepatocytes of mice with severe diabetes is not assumed to be affected by Sirt1, as this protein, when acting as histone deacetilase, would lead to a more compact state of the chromatin structure. Considering that the expressions of Sirt1 and PGC-1α in old mice differed from diabetic adult mice, we suggest that the early ageing observed in diabetic individuals does not follow the same metabolic pathway as natural ageing.

Effects of early undernutrition on the insulin sensitivity and on both glucose and ketone body transporters in the liver from suckling rats

E. Lizárraga-Mollinedo[1], E. Fernández-Millán[1], J. De Toro-Martín[2], C. Martinez-Honduvilla[2], C. Álvarez[1,2], F. Escrivá[1,2];
[1]Ciber de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM). ISCIII, [2]Bioquímica y Biología Molecular II, Facultad de Farmacia. Universidad Complutense, Madrid, Spain.

Background and aims: The suckling imposes biochemical adaptations to nutrition, since milk is a high-fat low-carbohydrate diet. As well, this period is a critical window of growth for the brain, which accomplishes part of its development before weaning. Immature brain uses large amounts of glucose and ketone bodies to obtain energy and for biosynthesis, thus increased rates of hepatic gluconeogenesis and ketogenesis are compulsory. Consistently, plasma insulin and glucagon remain in low and high concentration respectively, throughout the suckling, adapting liver metabolism to diet. What is more, hepatic low insulin responsiveness is the most suitable condition during this period. The shortage of nutrients during development can have grave consequences later in life. Impaired glucose tolerance, diabetes and cognitive defects can arise from early undernutrition. As previously shown, insulin responses are enhanced in heart, skeletal muscle and adipose tissue of restricted rats, but the effects on liver sensitivity has not been explored yet. Changes in hepatic insulin sensitivity might alter the rate of the indicated metabolic pathways, modifying the production of endogenous substrates. Our aim is to search whether maternal undernutrition influences the insulin responses in the liver of suckling pups.
Materials and methods: Wistar rats were submitted to a 60% restriction of a commercial diet from 14th day of pregnancy and during lactation. 10-day old rats from restricted dams and their controls were studied. Rats were decapitated. Blood was got from the neck. Liver was rapidly frozen. Plasma insulin and glucagon were determined by RIA. Glycogen was quantified with amyloglucosidase and ketone bodies spectrophotometrically. Liver gluconeogenesis was evaluated by a glycerol test. Components of insulin signalling were analyzed by Western. IRS-1/2 associated PI3-kinase was assayed with [^{32}P]ATP.
Results: Glycaemia was depressed in the restricted rats. Blood and liver ketone bodies remained above control values. Undernutrition decreased plasma insulin and glucagon. Liver glycogen was enhanced. Glycerol gluconeogenesis did not change, nor liver expression of insulin receptor, but IRS-1/2 increased with undernutrition. PI3-kinase was more activated by insulin in restricted rats, as was Akt and GSK3 phosphorylation.
Conclusion: Early undernutrition increases the risk for defects in glucose homeostasis and for neurological damages. Herein we show that undernourished rats are hypoglycaemic, due to the liver insulin hypersensitivity (as in other tissues) together with a low plasma glucagon. These changes mean a dramatic modification of the most convenient hepatic metabolic setting during suckling. The high ketogenic ability in restricted animals is rather surprising, considering the enhanced insulin responsiveness. The improved plasma levels of ketone body probably constitutes an adaptation to nutritional restriction. It might prevent or minimize the impact on immature organs, as the brain. However, glucose is required for normal brain functioning under most conditions, including perinatal time. So imbalance between plasma glucose and ketone body concentrations might have deleterious consequences for the developing brain.

The morphometric characteristics of pulmonary tissue and arteries in type 2 diabetic patients

O.A. Pivovarova[1], B.N. Mankovsky[2];
[1]Internal medicine №2, Lugansk State Medical University, Lugansk, [2]National Medical Academy of Postgraduate Education, Kiev, Ukraine.

Background and aims: Diabetes mellitus is associated with the damage of different organs. However, the changes of the lungs in patients with diabetes are not fully characterized. Therefore, the aim of our study was to investigate the morphometric characteristics of an alveolar tissue and pulmonary arteries in type 2 diabetic patients.
Materials and methods: We studied the materials obtained from the autopsy of 25 deceased subjects with type 2 diabetes mellitus (mean age - 58,3±1,3 years) and 11 deceased persons without diabetes (mean age - 50,2±1,6 years) as the control group. The causes of death in those subjects were not related to pulmonary disease. The tissue samples were sectioned and fixed in 10% neutral formol by standard histological methods and embedded in paraffin wax. The tissue slides were stained with hematoxylin-eosin. We analyzed the morphometric characteristics of pulmonary tissues and arteries using the light-optical microscope (Olympus, Japan, BX - 41).
Results: We found the trend toward an increase of the lumen of alveoli in those with diabetes compared to controls - 137,2±10,8 μm vs. 101,2±12,6 μm, respectively, 0,05<p<0,1 (data are presented as mean±SEM). These changes were accompanied by the significant decrease of the external diameter (100,8±1,6 μm vs. 172,3±27,4 μm, (p<0,001) and internal diameter (76,03±5,5 μm vs. 111,3±18,6 μm, (p<0,001) of pulmonary arteries in diabetic subjects compared to controls. Moreover, we found the significant decrease of the thickness of the arteries wall in those with diabetes (12,3±0,53 μm vs. 35,6±4,9 μm, (p<0,001), the vascular index was 14,3±0,42 vs. 22,6±0,97, (p<0,001), in those with and without diabetes, respectively.
Conclusion: We may conclude that the revealed morphometric changes of alveolar tissue and arteries in type 2 diabetic patients may underlie the higher susceptibility to pulmonary diseases in these patients.

Serum levels of bone turnover markers in type 2 diabetes and their relationship with bone mineral density

P. Rozas-Moreno[1], R. Reyes-García[2], M. Muñoz-Torres[2];
[1]Endocrinology Division, Hospital General de Ciudad Real, [2]Bone Metabolic Unit, Endocrinology Division, San Cecilio University Hospital, Granada, Spain.

Background and aims: Several studies indicate that hyperglycemia induces a low turnover state with osteoblast dysfunction. Studies of bone resorption in diabetes are limited, and the results are conflicting. Our aim was to analyse serum levels of bone turnover markers (BTM), PTH-i and 25 OH vitamin D in patients with type 2 diabetes mellitus (T2DM), and the relationship with bone mineral density (BMD). We also compared BTM between T2DM and controls.
Materials and methods: Case-Control study including 133 subjects, 78 patients with T2DM and 55 healthy controls. Lumbar spine and femoral BMD were measured by dual X-Ray absorptiometry (Hologic QDR 4500). We measured: bone alkaline phosphatase (b-ALP) by an ELISA (OCTEIATM IDS Ltd Boldon UK), osteocalcin (OC) by radioimmunoassay (DiaSorin, Stillwater, Minnesota USA; TRAP (Bone TRAP ® Assay. IDS Ltd); CTX by ELISA (Elecsys ß CrossLaps,Roche Diagnostics SL, Barcelona, Spain); PTH-i (Intact PTH, Roche Diagnostics SL); 25 OH vitamin D (25-Hydroxyvitamin D 125I RIA DiaSorin).
Results: Mean age was 56,7± 6,8 yr (57.8± 6.4 and 55,1± 7,1 in T2DM and control group respectively; p=0.024). Among the T2DM patients (n=78), 47.2% were females (n=35) and 52.8% males (n=43). In the control group 56.5% were females (n=30) and 43.5% males (n=25). Serum levels of bone resorption markers were lower in T2DM compared with controls (TRAP: T2DM 1.39±0.99 UI/l vs controls 1.85±0.81 UI/l, p<0.05; CTX: T2DM 0.20±0.12 ng/ml vs controls 0.33±0.15 ng/ml, p<0.05). There were no differences in bone formation markers (b-ALP: T2DM 14.83±6.5 ug/L vs controls 12.96±6.73 ug/L, p 0.11; OC: T2DM 1.48±1.25 ng/ml vs controls 1.45±1.2 ng/ml, p 0.91). PTH-i serum levels were lower in T2DM (PTH-i: T2DM 38.35±18.20 pg/ml vs controls 50.22±18.99 pg/ml, p<0.05). T2DM have lower levels of 25 OH vitamin D with respect to controls, although differences were not significant (T2DM 17.81±11.14 ng/ml vs controls 21.30±11.05 ng/ml, p 0.07). In T2DM there was a negative correlation between CTX levels and BMD at different sites (LS BMD -0.460, P<0.001; TF BMD -0.530, p<0.001).
Conclusion: T2DM patients have lower levels of bone resorption markers and PTH-i compared with controls. CTX serum levels were negatively correlated with BMD at different sites.

Predictors of impaired glucose regulation in patients with non-alcoholic fatty liver disease

E. Hatziagelaki[1], D. Karageorgopoulos[2], A. Chounta[3], A. Tsiavou[1], T. Economopoulos[1], M. Falagas[4];
[1]2nd Dept. of Internal Medicine, "Attikon" University Hospital, [2]Alfa Institute of Biomedical Sciences (AIBS), [3]4th Dept. of Internal Medicine, "Attikon" University Hospital, [4]Dept. of Medicine, Henry Dunant Hospital and Alfa Institute of Biomedical Sciences (AIBS), Athens, Greece.

Background and aims: Many patients with non-alcoholic fatty liver disease (NAFLD) have impaired glucose tolerance or type 2 diabetes mellitus (DM). We sought to identify characteristics of NAFLD patients associated with hyperglycemia.
Materials and methods: We prospectively studied a cohort of NAFLD patients. They underwent a 2-hour oral glucose tolerance test (using 75 g). Serum glucose and insulin were measured at 30 min intervals. Common biochemical laboratory tests were also done.
Results: We included 152 patients with NAFLD; 74 (48.7%) had hyperglycemia (45 had impaired fasting glucose or impaired glucose tolerance, and 29 had type 2 DM). Patients with hyperglycemia had higher body mass index (BMI; 30.5±4.5 vs. 28.5±4.8 kg/m2, p=0.01), lower high-density lipoprotein cholesterol (HDL-C; 46.5±13.6 vs. 53.7±18.8 mg/dL, p=0.02), lower serum albumin (4.1±0.5 vs. 4.4±0.4 g/dL, p<0.01) and were older (53.0±10.7 vs. 47.3±11.4 years, p<0.01), in comparison with patients with normoglycemia. In multivariate analysis including the above 4 variables as covariates, age (odds ratio [OR]: 1.08, 95% confidence interval [CI]: 1.03-1.13), BMI (OR: 1.12, 95% CI: 1.01-1.25), and HDL-C (OR: 0.95, 95% CI: 0.92-0.98) proved independent predictors of hyperglycemia in NAFLD patients. Additionally, 30-min insulin after the oral glucose challenge was lower in patients with hyperglycemia (74.2±49.7 vs. 94.5±53.9 μIU/ml, p= 0.02), while 90-min insulin (170.1±84.6 vs. 122.9±97.7 μIU/ml, p=0.01) and 120-min insulin (164.0±101.2 vs. 85.3±61.9 μIU/ml, p<0.01) were higher and insulin at 60-min did not differ between patients with or without hyperglycemia.
Conclusion: NAFLD patients with higher BMI, lower HDL-C, or older age were more likely to have impaired glucose metabolism. We suggest that oral glucose tolerance test should be considered for patients with non-alcoholic fatty liver disease, particularly in those with one or more with the above mentioned predictor characteristics of hyperglycemia, to readily diagnose and treat disorders of glucose metabolism.

1348

Non-alcoholic fatty liver disease in patients with type 2 diabetes mellitus

B. Resuli[1], F. Agaçi[2], B. Kraja[1], K. Sema[3], N. Dhigoi[1], M. Kapia[2], I. Burda[2];
[1]University Clinic of Gastrohepatology, University Hospital Center Mother Theresa, [2]University Clinic of Endocrinology, University Hospital Center Mother Theresa, [3]Clinic of Gastrohepatology, Ambulatory Service, Tirana, Albania.

Background and aim: Non-alcoholic fatty liver disease (NAFLD) is a growing medical problem worldwide. It has gained considerable attention for its appealing relations with insulin resistance and the slow-evolving course towards the end-stage liver disease. We conducted a prospective study of incidence and risk factors of NAFLD in patients with type 2 diabetes mellitus (DM).
Methods: 127 consecutive patients with type 2 DM [60 (47.2%) males and 67 (52.8%) females, mean age 59.3±9.3 years old] hospitalized in University Service of Endocrinology in Tirana, Albania during 2009 and fulfilling diagnostic criteria adopted by WHO 1999 were included in the study. The diagnosis of NAFLD was based on 1) sonographic findings, 2) ethanol intake equal or lower than 20 g/day and 3) exclusion of all other liver diseases. The clinical and laboratory parameters, such as age, sex, mean duration of diabetes, body mass index (BMI), glycosylated hemoglobin (HbA1c), transaminases levels, serum cholesterol and triglyceride levels were analyzed as predictors of sonographic findings by using multiple logistic regression model.
Results: 74% (N=94) of the patients had NAFLD [39/94 (41.5%) mild, 45/94 (47.9%) moderate, 10/94 (10.6%) severe]. The value of BMI, WHR (waist-hip ratio), ALT (alanine aminotransferase), serum cholesterol and triglyceride in type 2 DM patients with NAFLD were significantly higher than in those without NAFLD [26.5 vs. 33.9 kg/m^2, 0.91 vs. 1.12, 26.8 vs. 40.19 (UI/L), 193.9 vs.230.1 (mg/dl) and 141.7 vs. 227.9 (mg/dl), respectively, P<0.001). All patients (N=13; 14%) with ALT greater than normal had NAFLD. In multivariable-adjusted models significant predictors were age (OR=1.04, 95% CI=0.03-0.85), BMI (OR=1.53, 95% CI=0.10-0.32) and HbA1c (OR=1.1, 95% CI=0.11-0.23).
Conclusion: In Albania, the incidence of NAFLD seems to be higher in patients with type 2 diabetes mellitus. Older age, obesity and HbA1c were the independent risk factors of NAFLD in diabetic patients.

High prevalence of advanced NAFLD in type 2 diabetic patients with unremarkable liver enzymes and effect of liraglutide on NAFLD: meta-analysis of the LEAD Program

M.J. Armstrong[1], A. Falahati[2], B. Elbrønd[2], W.E. Schmidt[3], S. Gough[4], P.N. Newsome[1];
[1]Centre for Liver Research, University of Birmingham, United Kingdom, [2]Novo Nordisk A/S, Copenhagen, Denmark, [3]St-Josef Hospital, Ruhr-University Medical Faculty, Bochum, Germany, [4]Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of liver disease in type 2 diabetes. Predicting patients at risk of progressing to the advanced stages of NAFLD (liver inflammation and fibrosis) is a clinical challenge as the majority of patients are asymptomatic and have normal liver enzyme levels. The NAFLD Fibrosis Score (NFS) is a well-validated non-invasive scoring system (comprising age, BMI, AST:ALT ratio, platelets and albumin) used to predict the severity of advanced liver fibrosis. The aims of this study are: (i) to estimate the severity of NAFLD using the NFS and (ii) to evaluate the effect of 1.8mg liraglutide, a once-daily human GLP-1 analogue, on NAFLD in a cohort of poorly controlled diabetic subjects.
Materials and methods: Meta-analysis was performed on individual data from patients enrolled in the Liraglutide Effect and Action in Diabetes (LEAD) program. ANCOVA analysis was performed on the intent-to-treat population to estimate change from baseline after 26 weeks.
Results: Data from 3967 adults at baseline: 53% male; 79% Caucasian; Age 56 years [10]; HbA1c 8.3% [1.0]; duration of diabetes 7.8 years [5.8]; systolic BP 131 [15.3]; BMI 31.6 kg/m2 [5.40]; males ALT 32 and females ALT 24 IU/L (*values expressed as mean [SD]*). 70% of subjects had metabolic syndrome based on ATP III classification. 54% of subjects had abnormal ALT (upper limit of normal range 30 IU/L for males and 19 IU/L for females), with mean ALT 39 IU/L. The NFS predicted that 6.4% had advanced liver fibrosis (score > +0.676) and 61.0% had an indeterminate score (-1.455 to 0.676) requiring further liver specialist review. Duration of diabetes significantly correlated with ALT (r_s = 0.17, p<0.0001) and severity of NFS (r_s = 0.14, p<0.0001). Liraglutide significantly reduced ALT versus placebo (LS mean 3.48 vs 1.36; p<0.001), although the proportion of patients normalizing their ALT was similar (25.2% vs 22.7%). Liraglutide significantly improved NFS in comparison to placebo (LS mean -0.40 vs -0.13; p<0.0001), with significant changes in BMI (LS mean -0.66; p<0.0001) and platelet count (LS mean +15.90; p<0.0001). There was no relationship between changes in NFS and HbA1c after 26 weeks liraglutide treatment (r_s = 0.00, p 0.96).
Conclusion: Advanced NAFLD fibrosis is present in a significant proportion of diabetic patients in the LEAD program, despite the absence of clinically significant serum transaminases. Duration of diabetes, but not level of glycaemic control was correlated with elevation of ALT and worsening severity of NFS. 26 weeks treatment with Liraglutide reduces ALT and NFS. The increase in platelets after Liraglutide treatment may indicate an effect independent of weight loss in NAFLD.

Insulinaemic status and nonalcoholic fatty liver disease in Bangladeshi type 2 diabetic subjects

Z. Zeba, A. Alam, R. Zinnat, L. Ali;
Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is becoming a public health problem with increasing incidence and it has been shown to be associated with T2DM and other disorders of metabolic syndrome

(MS)). Insulin resistance (IR) is a central feature of both T2DM and MS, but the association of IR with NAFLD has yet not been fully clarified taking into account the racial heterogenecity and confounders like BMI. Moreover, the pathogenesis of T2DM Bangladeshi subjects has pancreatic β cell dysfunction as a predominant defect and its association with NAFLD needs to be investigated. The issue was addressed in this study through exploring the association of NAFLD with insulin secretion and sensitivity as measured by homeostasis model assessment.
Materials and methods: Under a Case-control design this analytic observational study was conducted on 127 T2DM with NAFLD and 129 T2DM without NAFLD subjects. T2DM was diagnosed by WHO Study Group Criteria and NAFLD was diagnosed by 4D ultrasound. Insulin was assayed by an ELISA technique, and insulin secretory capacity (HOMA% B) and insulin sensitivity (HOMA% S) were estimated by homeostasis model assessment using a HOMA-SIGMA software. Data were analyzed by appropriate univariate as well as multivariate tests including logistic regression analysis with NAFLD as dependent variable and others as independent/confounding variables as appropriate.
Results: The NAFLD group was found to have higher BMI as compared to the Control (BMI, M± SD, 26.19± 3.69 vs 25.32± 3.47, p= 0.053); however, no significant difference was observed in case of WHR. The fasting blood glucose and lipid levels did not differ between the two groups. Serum fasting insulin was significantly higher in case of NAFLD group [fasting serum insulin in IU/L, of NAFLDr vs Non-NAFLD, Median (Range), 19.8(3.0-81.6) vs 16.67(3-100.6), p=0.005]. HOMA%B was significantly higher in NAFLD group compared to T2DM subjects [HOMA%B, NAFLD vs Non-NAFLD, 108.9 (6.30-462.70) vs 90.8 (11.1-451.3), p=0.014]. In case of insulin sensitivity a significant difference was present between NAFLD and Non- NAFLD groups [HOMA%S, NAFLD vs Non-NAFLD, 31.9(5.8-212.10) vs 34 (6.8-190.8), p=0.005]. In logistic regression analysis, taking fatty liver as the dependent variable, and WHR, BMI, FBG, HOMA%S and HOMA%B as independent variables a significant negative association of fatty liver was found with HOMA% S (p= 0.033).
Conclusion: The data suggest that NAFLD is associated with insulin resistance in Bangladeshi T2DM subjects, and the association of IR and NAFLD is independent to obesity and glycemic- insulinemic status.

Alpha-lipoic acid attenuates steatohepatitis through inhibiting CYP2E1 and endoplasmic reticulum stress

M. Kim[1], G.-S. Jung[1], N.-K. Kim[1], H.-S. Kim[1], K.-G. Park[1], A.-K. Min[2], I.-K. Lee[2];
[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, [2]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is closely associated with obesity, and type 2 diabetes. In the insulin-resistant state, increased hepatic fat accumulation and reactive oxygen species (ROS) stimulates the activity of CYP2E1 and endoplasmic reticulum (ER) stress. Here, we examined whether alpha-lipoic acid (ALA) prevents steatohepatitis through the inhibition of molecular mediators involved in hepatic injury including CYP2E1 and ER stress.
Materials and methods: C57BL/6 mice were fed a methionine choline deficient (MCD) diet with or without ALA for 4 weeks. The plasma levels of ALT and AST were measured to check hepatic inflammation. For histological analysis, we conducted hematoxylin and eosin staining and Oil red O stating. We investigated the effect of ALA on CYP2E1 and ER stress in the liver of MCD-diet mice using Northern blot analysis and Western blot analysis.
Results: Dietary supplementation with ALA reduced MCD diet-induced hepatic lipid accumulation, hepatic inflammation and plasma ALT and AST levels. Upon histological examination, the livers of MCD mice exhibited steatohepatitis, including fat accumulation and infiltration by inflammatory cells. Mice fed an MCD diet supplemented with ALA exhibited significantly attenuated hepatic fat accumulation and inflammation. CYP2E1 expression in the liver of MCD mice was significantly higher than that of control mice, and ALA inhibited the MCD diet-induced expression of CYP2E1 at the mRNA and protein levels. Moreover, ALA inhibited MCD diet-induced expression of the nuclear factor-E2-related factor 2 (Nrf2) and Nrf2 target gene NAD(P)H quinone oxidoreductase 1. MCD diet increased the activation of ER stress markers, such as phosphorylation of eIF2α and expression of GRP78, ATF6, and CHOP, and also induced an increase in levels of MAP kinase activity, including JNK and ERK phosphorylation. MCD diet fed mice with ALA attenuated these expressions.
Conclusion: Taken together, the results of the present study indicate that ALA attenuates steatohepatitis through inhibition of CYP2E1 and ER stress. It provides the possibility that ALA can be used to prevent the development and progression of NAFLD in patients who have strong risk factors for NASH.

Specifically-PNPLA3-mediated accumulation of liver fat in type 2 diabetic patient

J.-M. Petit[1], B. Guiu[2], D. Masson[3], L. Duvillard[3], P. Buffier[1], M.-C. Brindisi[1], B. Bouillet[1], P. Hillon[1], I. Robin[1], J. Cercueil[2], B. Vergès[1];
[1]Diabetologie, [2]Radiology, [3]Inserm u866, CHU du Bocage, Dijon, France.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is commonly associated with obesity, metabolic syndrome and type 2 diabetes. Recently, it has been shown in the general population that an allele in the adiponutrin (PNPLA3) gene (rs738409[G]) was strongly associated with increased hepatic fat levels, independently of visceral adiposity and insulin resistance. In this study, we set out to determine whether liver fat content (LFC), evaluated using ^{1}H-MR Spectroscopy, was associated with PNPLA3 rs738409 polymorphism in people with type 2 diabetes. We also evaluated the influence of this polymorphism on the relationship between LFC and either visceral adiposity or intima media thickness (IMT).
Materials and methods: 218 type 2 diabetic patients were included in this study. LFC (1H-magnetic resonance spectroscopy), area of visceral fat (RMN), and IMT were measured.
Results: 139 (63.7 %) patients had steatosis. Patients with steatosis had a higher BMI (34.9 +/- 6.3 vs 32.9 +/- 6.6; p= 0.01), higher visceral fat area (284 +/- 94 vs 246 +/- 100 cm2, p= 0.005), higher plasma ALAT levels (42.8 +/- 22.5 vs 31.6 +/- 36.7 UI/l, p< 0.001), and higher plasma triglyceride levels (2.42 +/- 1.77 vs 1.78 +/- 1.05 mmol/l, p= 0.004) than did patients without steatosis. The rs738409 minor G allele was associated with LFC. The number of patients with steatosis is significantly higher among minor G allele carriers in comparison to C allele homozygote carriers (70.3% vs 57.2%; p=0.04) In the sub group of C allele homozygote carriers, LFC correlated with BMI (r=0.27, p=0.003), and visceral fat area (r=0.30, p=0.002) but not with IMT. In the sub group of minor G allele carriers, LFC correlated negatively with IMT (r=-0.23, p=0.03), but not with BMI, or with visceral fat area. Circulating triglycerides, total cholesterol, HDL cholesterol, LDL cholesterol, AST and ALAT levels were similar for minor G and C allele homozygote carriers.
Conclusion: This study suggests that in people with type 2 diabetes, LFC is related to rs738409 polymorphism. Moreover, an interesting finding of this study was that the relationship between metabolic factors and LFC were very different in each subgroup of the rs738409 polymorphism. The lack of a relationship with visceral obesity and the negative correlation with IMT suggest that fatty liver associated with the minor G allele of the PNPLA3 rs738409 polymorphism may not be linked to metabolic disorders. The reason why liver fat content is negatively associated with carotid atherosclerosis among PNPLA3-minor G allele carriers is not yet known. The possibility that in such patient, hepatic triglyceride synthesis could protect other tissues from the potential lipotoxicity of free fatty acids needs to be evaluated.

European Association for the Study of Diabetes

EASD Executive Committee

President:	U. Smith, Gothenburg (retires 2011)
Vice-President:	A.J.M. Boulton, Manchester (retires 2011)
Vice-President:	F. Bosch, Barcelona (retires 2012)
Honorary Secretary:	M. Stumvoll, Leipzig (retires 2010)
Honorary Treasurer:	G. Spinas, Zurich (retires 2010)
Chairman of the Postgraduate Education Sub-Committee:	J. Nolan, Dublin (retires 2010)
Editor-in-Chief, DIABETOLOGIA:	E. Gale, Bristol (retires 2010)

EASD Council comprises of the Officers above and the following members:

Term expiring September 2010	**Term expiring September 2011**	**Term Expiring September 2012**
F. Ashcroft, UK	T. Battelino, Slovenia	J.-M. Boavida, Portugal
V. Petrenko, Lithuania	D. Matthews, UK	C.-G. Östenson, Sweden
A. Siebenhofer, Austria	J. Philippe, Switzerland	A. Pfeiffer, Germany
	J. Zierath, Sweden	N. Wareham, UK

The Past President, E. Ferrannini, and the Secretary of the Postgraduate Education Sub-Committee, L. Czupryniak, are members of the Council ex officio.

HONORARY AUDITORS
K. Patterson, Glasgow and C. Tack, Nijmegen

HONORARY MEMBERS
G. Alberti, Newcastle; D. Andreani, Rome; J.-P. Assal, Geneva; E. Cerasi, Jerusalem; O.-B. Crofford, Melbourne (USA); A. Czyzyk, Warsaw; J.K. Davidson, Atlanta; T. Deckert, Hellerup; P.
